A WEEKLY

Cuk-H06634-119-RP249

ILLUSTRATED JOURNAL OF SCIENCE

119

VOLUME CXIX

JANUARY, 1927, to JUNE, 1927

"To the solid ground
Of Nature trusts the mind which builds for aye."—WORDSWORTH.

London
MACMILLAN AND CO., LIMITED
NEW YORK: MACMILLAN COMPANY

INDEX.

NAME INDEX.

Abbot (Dr. C. G.), Solar Radiation, 212; The Number of the Stars, 903
Abbott (W. J. Lewis), The Microscopical Examination of Flint Surfaces, 747
Abelous and Argaud, The Different Vicariant Modalities in Animals without the Spleen, 303
Achard (C.), L. Binet, and A. Leblanc, Death in a Superoxygenated Atmosphere, 658
Achard (M.), The First British Locomotives of the St. Etienne-Lyon Railway, 402
Adam (N. K.), The Polishing of Surfaces, 162, 279
Adams, Joy, and Humason, Spectroscopic Parallaxes, 331
Adcock (F.), Dr. M. L. V. Gayler, and N. P. Tucker, The Production of Pure Chromium, Manganese, and Silicon, 833
Addenbrooke (G. L.), Rotation of Bodies with Dielectric Surfaces in Electrostatic Fields, 389
Addison (Col. G. H.), The Work of the Royal Engineers in the European War, 1914–1918. Miscellaneous, 811
Adler (Dr. S.), and O. Theodor, The Behaviour of Cultures of *Leishmania tropica*, *L. infantum*, and *L. brasiliense* in the Sandfly, *Phlebotomus papatasii*, 48; The Behaviour of Cultures of *Leishmania* sp. in *Phlebotomus papatasii*, 565
Aiyer (T. V. Ramakrishna), Some Indian Lepidoptera with Abnormal Habits, 146
Allan (Dr. G. E.), Tuning-Forks with Parallel Prongs, 281
Allen (Grant), The Story of the Plants. New edition, Mar. 19, Suppt., 10
Allen (Dr. G. M.), Birds and their Attributes, Mar. 5, Suppt., 2
Allen (Prof. H. S.), New Quantum Theories, 77; Spinning Electrons and Protons, 237; and I. Sandeman, Bands in the Secondary Spectrum of Hydrogen, 412
Allen (Prof. P. W.), Industrial Fermentations, 741
Altchidjian (Y.), The Utilisation of Liquid Fuels containing a High Proportion of Organic Sulphur Compounds as a Source of an Antidetonating Combustible, 71
Amar (J.), Oxygen-carbon Dioxide Antagonism, 106; The Origin and Evolution of Cancer, 878
Ambronn (H.), und A. Frey, Das Polarisationsmikroskop: seine Anwendung in der Kolloidforschung und in der Farberei, Mar. 5, Suppt., 5
Amery (Mr.), Speech to the Colonial Conference, 755
Ames (Dr. J. S.), elected chairman of the U.S. National Advisory Committee for Aeronautics, 900
Amirthalingam (C.), Structure of Pearls, 854
Amos (A.), reappointed director of the Farm of Cambridge University, 411
Andrade (Prof. E. N. da C.), Light and Electricity, 101; The Structure of the Atom. Third edition, 554
André (E.), and H. Canal, The Oil of *Mesoplodon bidens*, 106
André (Prof. G.), [death], 933
André (H.), The Electrical Properties of Some Metallic Compounds, 658
Andrew (G.), Petrographic Notes on Specimens in the 'David Forbes' Collection of Rocks in the Manchester Museum, 767
Andrews (Dr. R. C.), On the Trail of Ancient Man: a Narrative of the Field Work of the Central Asiatic Expeditions, 521
Andrieux, A Method of High-temperature Electrolysis of Oxygen Compounds, 302
Anniss (L. G.), The Geology of the Saltern Cove Area (Torbay), 545
Antoniadi (E. M.), Changes observed on the planet Jupiter, 146
Appleton (Prof. E. V.), Eclipse Phenomena, 898; Wireless Transmission and the Upper Atmosphere, 679
Appleyard (E. T. S.), Action of Magnetic Fields on the Refractive Index of Carbon Dioxide Gas, 353
Armellini (G.), Horizontal Diameter of the Sun in 1925 and 1926, 690
Armstrong (Dr. E. F.), The Romance of the Organic Chemical Industry, 289
Armstrong (Prof. H. E.), Carbon Monoxide Poisoning in the Absence of Hæmoglobin, 460; Oxygen = 17.00, 51; The Horace Brown Memorial Lecture, 399; Prof. Ira Remsen, 608; Prof. E. H. Rennie, 431
Arnall (Dr. F.), and F. W. Hodges, Theoretical Organic Chemistry. Part 1, Mar. 19, Suppt., 16
Asdell (S. A.), and F. H. A. Marshall, Effect of the Ovarian Hormone in producing Pro-œstrous Development in the Dog and Rabbit, 220
Ashby (E.), Biological Fact and Theory, 456; The Flora of the Grampian Mountains of Victoria, Australia, 104
Ashworth (Prof. J. H.), Distribution of Anopheline Mosquitoes in Scotland, 513, 766
Aston (Dr. F. W.), A New Mass-spectrograph and the Whole-number Rule (Bakerian Lecture), 945; The Constitution of Mercury derived from Coal Tar, 489
Astruc (A.), and M. Mousseron, The Various Soluble Ferments contained in Black Mustard (*Brassica nigra*), 303
Atkin (W. R.), Development of the Sörensen Equation for the Isoelectric Points of Ampholytes, 398
Atkins (Dr. W. R. G.), The Soluble Silicate Content of Soils, 893
van Aubel (E.), The Calculation of the Refractive Indices of Mixtures and the Formulæ of Dieterici and Lichtenecker, 414; The Thermoelectric Power of Alloys, 414; The Viscosity of Liquid Chlorine, 373
Aurousseau (M.), Analyses of Three Australian Rocks, 263
Austin (Prof. J. H.), and Prof. G. E. Cullen, Hydrogen Ion Concentration of the Blood in Health and Disease, 742
Awbery (J. H.), and Dr. Ezer Griffiths, Further Experiments with the Ewing Ball-and-Tube Flowmeter, 105; A Ball and Tube Flowmeter suitable for Pressure Circuits, 657

Back (E. A.), and R. T. Cotton, The Biology of the Saw-toothed Grain Beetle, 368
Baglioni (S.), L. Bracaloni, and A. Galamini, Investigation on the Physiological Action of Alcohol, 414, 479
Baglioni (S.), and A. Galamini, Physiological Action Alcohol (iii), 767
Bahl (Prof. Karm Narayan), The Indian Z Memoirs on Indian Animal Types. 1: (The Common Indian Earthworm), 557
Baikie (Rev. J.), The Amarna Age: a St of the Ancient World, 851
Bailey (E. B.), Granite Domes of Vre James Hutton: Father of 1797, 582

Bailey (M. A.), and T. Trought, Field Trials with Cotton, 214 ; The Cotton Plant, 869

Baird (J. L.), Television, 73, 101, 161, 865

Baize (P.), The Orbit of 61 Cygni, 403

Baker (C.), List of Second-hand Scientific Instruments, 25 ; Microscopes and Accessories, 172

Baker (Dr. E. A.), Density of the Photographic Image, 685 ; Measurement of Radiation Intensity by Photographic Methods, 707 ; The Law of Blackening of the Photographic Plate at Low Density (second paper), iv., 105

Baker (G. S.), The Value of Tank Testing, 296

Baker (Prof. H. B.), Experiments on Molecular Complexity, 510 ; and H. L. Riley, The Atomic Weight of Silver, 348, 703

Baker (T. Thorne), Wireless Pictures and Television : a Practical Description of the Telegraphy of Pictures, Photographs, and Visual Images, 887

Balavoine (P.), The Refractive Estimation of Alcohol in Fermentation Products, 587

Baldwin (J. M.), The Technique of the Nanson Preferential Majority System of Election, 35

Balfour (H.), Archæology in South Africa, 226 ; Coup-de-Poing, 490

Balfour (Lord), The Pollution of Rivers and Estuaries, 327

Ball (Prof. N. G.), Transmission of Stimuli in Plants, 638

Ballantyne (Miss Frances M.), Air-bladder and Lungs : a Contribution to the Morphology of the Air-bladder of Fish, 181

Balls (Dr. W. L.), appointed director of the Botanical Section of the Egyptian Ministry of Agriculture, 402

Bamber (Ruth C.) (Mrs. Bisbee), A Simple Method of Demonstrating the Anatomy of Trematodes, 766

Bannister (C. O.), Crystallisation of Silver Beads and Detection of Platinum Metals by the Microscope, 766

Banta (Dr.), Genetics at the Carnegie Institution of Washington, 904

Banting (Prof. F. G.), awarded the Cameron prize of Edinburgh University, 258

Barber (D. R.), A New Type of Primary Cell, 892

Barbieri (U.), Determination of Astronomical Latitude carried out at Andrate in August 1926, 623

Barclay (D.), H. M. L. Bolus, and E. J. Steer, A Book of South African Flowers, 557

Barfield (R. H.), Effect of a Large Number of Receiving Aerials on the Propagation of Wireless Waves, 195

Barkla (Prof. C. G.), Modified Scattered X-Radiation due to Super-Position, 778 ; and Dr. G. A. Carse, Notes on Practical Physics : for Junior Students, Mar. 19, Suppt., 15

Barnard (C.), A Dicotyledonous Fossil Wood from Ulladulla, N.S.W., 948

Barnard (J.), [death], 754

Barnard (J. E.), J. Smiles, and F. V. Welch, The Morphology of Filterable Viruses, 583

Barnard (J. E.), and F. V. Welch, Practical Photo-Micrography. Second edition, 313

Barnes (Prof. H. T.), Destruction of Icebergs, 761

Barr (G.), and Isabel Hadfield, Effect of Sunlight on Cotton, 255

Barré, A New Method of Preparing a-ketonic Acids, 690

Barrett (Sir William), and T. Besterman, The Divining-Rod : an Experimental and Psychological Investigation, 310

Barritt (N. W.), The Occurrence of Branched Lint Hairs in Egyptian Cotton, 392

Barry (T. H.), Arsenic in Printing Ink, 413

Bartholomew (Miss E. M.), and G. J. Burrows, The Preparation of certain Iodo-bismuthates, 222

artlett (E. P.), Compressibility of Hydrogen and Nitrogen, 797 ; Concentration of Water Vapour in Compressed
, 440
(Prof. H. B.), elected president of the Botanical
of America, 171
) Ionisation in Hydrogen Chloride Vapour,

Demonstration of the Interdependence
and Haüy's Laws, 623
Mary E. Quick, Mollusc as Agent in
Disease, 295

Barus (Dr. C.), Pinhole Probe Experiments with Massive Air Columns, 838

Bastings (L.), Temperature Coefficient of γ-Ray Absorption, 51

Bate (S. C.), The Synthesis of Benzene Derivatives, 520

Bateson (Dr. W.), an appreciation of, 828

Bather (Dr. F. A.), Amphipneustes, 460 ; Biological Classification, 329 ; elected president of the Geological Society of London, 330 ; The Development of Natural History Museums, 639

Batschinski (Prof. A.), A New Pressure-Temperature Formula for Vapours, 198

Bauer (Dr. L. A.), Atmospheric Electricity, 457

Baxter (G. P.), and H. W. Starkweather, The Density of Oxygen and its Compressibility below One Atmosphere (ii), 339

Bayard (F. Campbell), [death], 326

Bayne (C. S.), Exploring England : an Introduction to Nature-craft, 668

Bayol (J.), P. Marcelin, and L. Mayet, A Cave with Drawings on the Walls of the Reindeer Age in the Valley of Gardon, 910

Beacall (T.), Dr. F. Challenger, Dr. G. Martin, and Dr. H. J. S. Sand, Dyestuffs and Coal-Tar Products : their Chemistry, Manufacture and Application. Fourth edition, Mar. 9, Suppt., 17

Beard (J. R.), Electricity Supply, 542

Beasley (H. C.), A Crystal Mask from Tibet, 174

Beaufoy (Mark), centenary of the death of, 792

Beaver (Prof. J. L.), Elements of Alternating Currents and Alternating-current Apparatus, Mar. 9, Suppt., 18

Beck (C.), Measuring Zonal Aberrations, 440 ; The Best Method of Illuminating Metallurgical Specimens, 766

Beckett (Dorothy), The Influence of Separation and Pasteurisation on the Size and Distribution of Fat Globules in Milk and Cream, 658

Becquerel (Prof. J.), Cours de physique à l'usage des élèves de l'enseignement supérieur et des ingénieurs, Tome 2, 850 ; L'Art musical dans des rapports avec la physique, Mar. 5, Suppt., 8

Bedford (G. A. H.), Three New Species of Anoplura from South African mammals, 838

Bedford (T. G.), appointed lecturer in physics in Cambridge University, 835

de Beer (G. R.), An Introduction to Experimental Embryology, 114

Bělař (Dr. K.), Der Formwechsel der Protistenkerne : eine vergleichend-morphologische Studie, Mar. 5, Suppt., 4

Bell (A.), The Free Place Scholarships Examination, 1926, in Kent, 219

Bell (F. A.), appointed secretary of the Faraday House Electrical Engineering College, 619

Belling (Dr. J.), Multiple Chromosomes and Reduction Division in Flowering Plants, 122 , The Nodes at the Reduction Division in Bivalents of Hyacinthus, 527 ; The Nomenclature of Chromosome Groups, 926

Belloc (Hilaire), A Companion to Mr. Wells's "Outline of History," 75 ; Mr. Belloc still objects to Mr. Wells's "Outline of History," 75 ; Is Darwinism Dead ? 277, 427, 526

Benedict (Dr. F. G.), and E. G. Ritzman, The Fasting of Large Ruminants ; The Basal Metabolism of Steers ; The Metabolic Stimulus of Food in the Case of Steers, 839

Benndorf (H.), Contributions to our Knowledge of Atmospheric Electricity (No. 68), 911

Bennett (A. L.), awarded the Frank Smart prize in zoology of Cambridge University, 943

Bennett (Prof. E.), and Dr. H. M. Crothers, Introductory Electrodynamics for Engineers, 595

Benson (Prof. W. N.), Tectonics and Petrogenesis, 761

TITLE INDEX.

a-Bromoaldehydes, A Method of Synthesis of, A. Kirrmann, 547
a-particles from Radium C: The decrease in Velocity of, G. H. Briggs, 301; The Straggling of, G. H. Briggs, 301
a- and β-particles through Matter, The Passage of, Dr. E. J. Williams, 262
Aberystwyth, Prof. H. Stuart Jones appointed principal of the University College of Wales, 688
Abnormal Discharge, A New Phenomenon in the, Güntherschulze, 215
Absorption of Gases by Liquids, An Apparatus for Measuring the Rates of, P. Riou, 373
Abyssinia, An Expedition to, H. Scott, 836
Abyssinian, South, frontier, anthropological expedition to the, 248
Acacias, Description of Fifteen New, and Notes on several other Species, late J. H. Maiden and W. F. Blakely, 222
Académie des Sciences, Paris, Members and Correspondants of the, L., 459
Accident Rates, Individual Difference in, E. Farmer and E. G. Chambers, 332
Acclimatisation and High Altitudes, D. V. Latham, 65
Acetone, Properties of, 27
Acetylene, The Addition of, to Carbon Monoxide: the Synthesis of Quinone, J. F. Durand and M. Banos, 837
Acid Soils, The Lime Requirements of, C. Brioux and J. Pien, 183
Acoma, The Sky City: a Study in Pueblo-Indian History and Civilization, Dr. W. T. Sedgwick, 44
Acoustical Experiments with a Mechanical Vibrator, E. Mallett, 657
Acoustics of Buildings, The, Dr. G. W. C. Kaye, 603
Acrolein Gels: Peculiarities of the Fractures of, Rhythmic Productions of Ridges, C. Dufraisse and P. Gailliot, 71
Aculeate Hymenoptera of Ireland, The, A. W. Stelfox, 413
Adams prize of Cambridge University, Dr. H. Jeffreys awarded the, 436
Adelaide University, Dr. H. H. Woollard appointed professor of anatomy in, 503
Adhesives and Adhesions: True Chemical Compounds as Adhesives, Prof. J. W. McBain and W. B. Lee, 181
Adolescent, Education of the, Report of the Consultative Committee on the, 185
Adrenal Cortex, The Chemistry of the, Dr. A. v. Szent-Gyorgyi, 782
Adrenaline exist in the completely Free State in Fresh Suprarenal Capsules of Does, A. Mouriquand and A. Leulier, 221
Adsorption, The Dipole Theory of, An Experimental Test of, W. G. Palmer, 801
Aerial: Navigation, Artificial Light in connexion with, H. N. Green, 434; Waves, The Propagation of, in Large Subterranean Cylindrical Mains, J. Thovert, 546
Aeronautical Pioneers, a Memorial Tablet to Three, at Cambridge, 757
Aeroplane: Flight, a Non-stop, by, C. Chamberlin and Mr. Levine, 865; Flights, Recent Long-distance, 782; Resistance and the Tilt of an, What determines the, Sir Joseph Larmor, 445, 798; The Book of the, Capt. J. L. Pritchard, Mar. 19, Suppt., 20
Africa: East, a New Dominion: a Crucial Experiment in Tropical Development and its Significance to the British Empire, Major A. G. Church, 917; Tropical, Problems in, 917
African Languages and Culture, International Institute of, The, 22
Agassiz Medal of the U.S. National Academy of Sciences, Dr. M. Weber awarded the, 793
Age and Area, Dr. J. C. Willis, 795
Agricultural Research and Administration in the Non-self-governing Dependencies, Report of Commission on, 670; in 1925, 312; Surveying, including Mensuration, Road Construction and Drainage, J. Malcolm, Mar. 19, Suppt., 12
Agriculture: Ministry of: Retirement of Sir Daniel Hall from the director-generalship of the Intelligence Department of the, 866; H. V. Taylor appointed Horticultural Commissioner of the, 171; The Beginning of, Prof. G. Elliot Smith, 81; Prof. J. Percival, 157; H. J. E. Peake, 158; Beginnings and the Early Spread of, H. J. E. Peake, 894
Air-bladder and Lungs: a Contribution to the Morphology of the Air-bladder of Fish, Miss Frances M. Ballanty[illegible] [illegible]81
Air Elutriation, The Laws of, Dr. G. Martin, 23
Alaska, Tides and Currents in, Lieut. R. W. Woodworth and F. J. Haight, 684
Ala Temporalis and Alisphenoid Bones, Homology of the, Dr. Kesteven, 99
$AlCl_3$—KCl—H_2O at 25°, The System, G. Malquori. 911
Alcohol: in Fermentation Products, The Refractometric Estimation of, P. Balavoine, 587; The Physiological Action of, S. Baglioni, L. Bracaloni, and A. Galamini, 414, 479; (iii.), S. Baglioni and A. Galamini, 767
Algæ, The Perforating, their Distribution and their Rôle in Nature, G. Nadson, 838
Algebraic Equations, Numerical Solution of, Dr. H. Jeffreys, 565
Alkali Chlorides, Luminescence and Coloration of, when treated with Becquerel rays, E. Jahoda, 107
Alkaloids: Plants Yielding, Lt.-Col. A. T. Gage, 909; The Knowledge of, Dr. T. A. Henry, 909
Allothrombium fuliginosum Hermann, Development of, S. Hirst, 260
Alloy Crystals, Tensile Tests on. Parts i., ii., and iii., C. F. Elam, 877
Alloys: Binary, The Magnetic Susceptibility of some, J. F. Spencer and E. M. John, 477; Eutectic, The Structure of, F. Hargreaves, 584; Hardness of, A. Mallock, 669; Inverse Segregation in, the Mechanism of, R. Genders, 585; Magnetisation in, L. W. McKeehan, 140; Non-magnetic, Magnetic Analysis as a Means of Studying the Structure of, K. Honda and H. Endo, 585; of Iron and Manganese of Low Carbon-Content, Sir Robert Hadfield, 545; The Thermoelectric Power of, E. van Aubel, 414
Almanack, An, for the Year of our Lord 1927. Complete and abridged editions, J. Whitaker, 80
Alternating: Current Rectification and Allied Problems: a Mathematical and Practical Treatment from the Engineering View Point, L. B. W. Jolley. Second edition, Mar. 19, Suppt., 18; Currents: Alternating-current Apparatus, Elements of, Prof. J. L. Beaver, Mar. 19, Suppt., 18; Measuring, Instruments for, Lt.-Col. K. Edgcumbe and F. E. J. Ockenden, 334
Aluminium: Film Filter in Telephony, An, Siegmund, 797; Single Crystal of, The Thermal and Electrical Conductivity of a, Dr. E. Griffiths, 545; Surface Film of, H. Sutton and J. W. W. Willstrop, 673, 924; W. H. Withey, 923
Amarna Age: The, a Study of the Crisis of the Ancient World, Rev. J. Baikie, 851
Amateur Botanists, The Society of, J. Ramsbottom, 104
Amber, the Klebs Collection of, procured for the Geological Institute of Königsberg University, 24
America: Civilisation in, The Origin of, Prof. G. Elliot Smith, 3; Physical Types and Cultures in, Dr. A. Hrdlička, 294
American: Geophysical Union, Annual Meeting of the, 757; Institute of Chemical Engineers, Dr. E. R. Weidlein elected president of the, 63; -Indian Music and Musical Instruments, Dr. P. Rivet, 614; Mathematical Society, The, 613; Mongolian Expedition, The, Prof. J. W. Gregory, 521; Roentgen Ray Society, forthcoming meeting in Montreal, 827
Amines, Liquid and Vapour, Absorption Bands of, E. O. Salant, 926

Ammonia: Decomposition of, by Optically Excited Mercury Atoms, R. G. Dickinson and A. C. G. Mitchell, 339; Hydrogen Mixtures, Ionic Mobilities in, and an Anomalous Effect of Ammonia, L. B. Loeb, 338; in the Silent Discharge, Formation of, Warburg and Rump, 369; The Thermal Decomposition of, upon the Surface of a Molybdenum Wire, R. E. Burk, 731
Ammonites, Yorkshire, Dr. L. F. Spath, 543
Amœbæ in Motion, New Imitations of, A. L. Herrera, 767
Amphibole of the Glaucophane Group, An, L. Duparc, 767
Amphipneustes, Dr. F. A. Bather, 460
Anagallis, An Unusual Specimen of, Eleanor Vachell, 513
Anatomical Texts, Medieval, Dr. G. W. Corner, 939
Anatomy: Descriptive and Applied, H. Gray. Twenty-third edition, edited by Prof. R. Howden. Notes on Applied Anatomy revised by J. Gray and Dr. J. D. Lickley, 921
Ancient Cities and Modern Tribes: Exploration and Adventure in Maya Lands, Dr. T. W. Gann, 681; Cottages, The Preservation of, Mr. Baldwin, 503; Man: on the Trail of, a Narrative of the Field Work of the Central Asiatic Expeditions, Dr. R. C. Andrews, 521
Andromede (or Bielid) Meteor Storms, The Apparition Dates of the, W. J. Fisher, 339
Anguilla rostrata, hatching out eggs of, Marie Poland Fish, 290
Anhydrous Borates of Silver, Barium, and Zinc, F. De Carli, 479
Anilopyrine and Antipyrine, P. K. Dutt, 35
Animal: Ecology, Prof. A. S. Pearse, 193; Nutrition in Sweden and Denmark, Dr. H. E. Woodman, 486; Parasites and Human Disease, Dr. A. C. Chandler. Third edition, 885
Animals: Looking into the Future, Prof. W. A. Kepner, 233; Slaughtering, British and American Methods of, H. Kidd, 864; without the Spleen, The Different Vicariant Modalities in, Abelous and Argaud, 303
Anisogeny, A Suggested Interpretation of Certain Cases of, R. J. Chittenden and Caroline Pellew, 10
Annual Register: The, 1926, Edited by Dr. M. Epstein, 889
Anopheline Mosquitoes in Scotland, Distribution of, Prof. J. H. Ashworth, 513, 760
Anoplura, Three New Species of, from South African Mammals, G. A. H. Bedford, 838
Antarctic: Echinoidea, Prof. R. Koehler, 294; Marine Crustacea of the, T. Monod, 294; Meteorology, 139; Projected Flying Expedition to the, 364; Two-way Communication with the, W. H. Brown, 238, 289
Anthropologie, Grundriss der, Dr. M. W. Hauschild, Mar. 5, Suppt., 1
'Antiknocks,' The Action of, A. Egerton and S. F. Gates, 427
Antimonic Ion, The Iodometric Estimation of the, A. Travers and Jouot, 587
Antimony Trichloride as a possible quantitative reagent for Vitamin A, F. Wokes and S. G. Willimott, 837
Antiquity: a New Quarterly, 363; Pt. I., 576
Aphis rumicis L., On the Occurrence of Intermediates in, J. Davidson, 546
Aplocheilus latipes, The Development of Mendelian Characters in, H. B. Goodrich, 147
Arabia: In Unknown, Major R. E. Cheesman, 381; Pre-Sumerian Man in, L. H. Dudley Buxton and H. Field, 651
Arachnides de France, Les, E. Simon. Tome sixième. Deux. partie. Mar. 5, Suppt., 3
Archæology in South Africa, H. Balfour, 226; of the Channel Islands, Dr. R. R. Marett, 20
Archiplasma: Das, Betrachtungen uber die Organisation des Pflanzenkorpers, Prof. H. Miehe, 628
Arctic: Land in the, 763; Ice, The Distribution of, 615; Plant in Ireland, An, A. W. Stelfox, 781
Ardsheal Hill, The Igneous Geology of, F. Walker, 106
Argon, The Spectrum of, K. W. Meissner, 398
Armstrong College, resignation of Prof. D. A. Gilchrist, 411; resignation of Prof. J. W. Bews; J. W. Harvey appointed professor of philosophy, 765; C. Heigham appointed professor of agriculture; Dr. J. W. Heslop Harrison appointed professor of botany; J. Holmes appointed lecturer in geography, 944
Army, Health of the, Report for 1925, 648
Arrow-release, A. L. Kroeber, 904
Arsenic in Printing Ink, T. H. Barry, 413
L'Art musical dans ses rapports avec la physique, Prof. J. Becquerel, Mar. 5, Suppt., 8
Artificial Silk, T. Brough, 140
Artists, Distinctive Colour Senses of, Sir Arthur Schuster, 783
Aspartic Esters, The Rotatory Dispersion of Certain, F. P. Mazza and G. D. Jojo, 767
Aspergilli, The, C. Thom and Margaret B. Church, 386
Aspergillus niger, Formation of Organic Acids from Sugars by, Dr. F. Challenger, V. Subramaniam, and Dr. T. K. Walker, 674
Astronomical Latitude carried out at Andrate in August 1926, Determination of, U. Barbieri, 623

ASTRONOMICAL NOTES.

Comets:
  Comet Comas Sola, 64; Comets, 137, 173, 212, 252; Return of the Comet Pons-Winnecke, The, 403; A New Comet, 437; Comets, 471, 505; Comet Grigg-Skjellerup, 539; Comets, 578, 650, 759, 938
Instruments:
  A New Reflecting Telescope for Edinburgh, 173
Meteors:
  Brilliant Fireball on Feb. 25, W. F. Denning, 366, 403; Fireball of Mar. 1, W. F. Denning, 471; The Bielid Meteor Showers, W. J. Fisher, 539; The Detonating Meteor of Oct. 2, 1926, F. J. Whipple, 578; A Fireball on June 10, W. F. Denning, 938
Observatories:
  The Solar Physics Observatory, Cambridge, 25
Planets:
  The Minor Planets, Prof. H. N. Russell, 137; Satellites of Mars, A. Hall, E. C. Bower, and Miss E. A. Lamson, 137; Mercury as an Evening Star, C. Schoch, 252; Photographs of Mars in 1926, F. E. Ross, 252; The Comas Sola quickly-moving Asteroid, 293; The Planet Neptune, M. E. J. Gheury de Bray, 293; Mercury as an Evening Star, C. Schoch, 505; The Position of the Axis of Mars, 829; Photographs of Mars, 938
Stars:
  Observations of Proxima, Innes and van den Bos, 25; The Distant Companion of Castor, Prof. H. N. Russell, 25; A New Photographic Star Catalogue, 98; The Distribution of Intensity in Stellar Absorption Lines, Miss Payne and Dr. Shapley, 98; Statistical Properties of Galactic Cepheids, J. Schilt, 212; Spectroscopic Parallaxes, Adams, Joy, and Humason; A. V. Douglas, 331; The Orbit of 61 Cygni, P. Baize, 403; Proper Motions of Faint Stars, Dr. W. M. Smart; Dr. H. Knox Shaw, 471; Southern Double Stars, W. H. van den Bos, 505; Kordylewski's Variable Star, 613; Globular Clusters and Spiral Nebulæ, A. R. Hinks, 725; Recent Sunspot Activity, 759
Sun:
  Sunspot Activity, 1926–27, 64; Recent Sunspot and Magnetic Disturbance, 98; Weather Conditions in Norway for the Eclipse of June 29, 1927, K. Kordylewski and Z. Eckstein, 98; A Large Sunspot, 173; Solar Radiation, Dr. C. G. Abbot, 212; Sunspot Frequencies and Terrestrial Phenomena, Prof. T. Terada, 293; Solar Radiation, R. Sekiguti, 366; The Sun's Motion derived from Faint Stars, P. van de Kamp, 366; Radio Reception and Solar Activity, G. W. Pickard, 437; Solar Eclipse of June 29, 437; The Coming Solar Eclipse, 682; A. J. Hawkes, 794
Miscellaneous:
  Another Repetition of the Michelson-Morley Experiment, R. J. Kennedy, 64; The Observer's Handbook for 1927 (Royal Astronomical Society of Canada), 293; A Fixed Easter, 331; Calendar Reform, M. B. Cotsworth, 613; Astrophysics in Russia, 725; New Determinations of the Velocity of Light, 794; Royal Astronomical Society's Annual Report, 794; Exploded Wires, Prof. H. N. Russell, 829; Rare Astronomical Books, 938

Astronomy: Elementary, 593; Modern, its Rise and Progress, Dr. H. Macpherson, Mar. 19, Suppt., 13; The Elements of, a non-mathematical textbook for use as an introduction to the subject in colleges, universities, etc., and for the general reader, Prof. E. A. Fath, 593
Astrophysics in Russia, 725
Athenæum Club: E. G. Dawber, Sir John Reith, and Prof. G. I. Taylor elected members of the, 211; Sir Sydney Chapman, Sir Alexander Gibb, and Sir Israel Gollancz elected members of the, 364; Sir James Berry, Sir H. Walford Davies, and Sir Frederick Keeble elected members of the, 538
Athletes, Rate of Work done by, Prof. A. S. Eve and A. J. Fleming, 86
Atlantic Ocean, The, Sir Gilbert Walker, 169
Atmosphere, The Structure and Movement of the, as affected by Diurnal Variations, A. H. R. Goldie, 803
Atmospheric: Circulation, Dr. H. Jeffreys, 194; Electricity, Dr. L. A. Bauer, 457; Dr. C. Chree, 458; Our Knowledge of (No. 68), H. Benndorf, 911; The Problem of, Prof. P. G. Gundry, 67; Impurity and Electricity Supply, Relationship between, J. B. C. Kershaw, 647; Ionisation, Prof. J. J. Nolan and G. P. de Sachy, 105
Atmospherics, The Range of, R. A. Watson Watt, 689
Atom and Molecule, Conceptions of the, due to Avogadro and Cannizzaro, Prof. Nasini, 435; The Structure of the, Prof. E. N. da C. Andrade, Third edition, 554
Atomdynamik, Probleme der, Prof. Max Born. Erster und zweiter Teil, 77
Atome: Die Welt der, Zehn gemeinverständliche Vorträge, Prof. A. Haas, 419
Atomic: Fields, The Calculation of, L. H. Thomas, 34; Hydrogen, The Dispersion of, R. M. Langer, 147; No. 61, L. Rolla and L. Fernandes, 374; Existence of the Element of, R. Brunetti, 374; Identification of the Element with, R. Brunetti, 374; Nuclei, Disintegration of, by α-particles, The Views of the Cambridge and Vienna Schools on the, 901; Physics, 554; Prof. O. W. Richardson, 905; Prof. A. Sommerfeld, 797; Three Lectures on, Prof. A. Sommerfeld. Translated by Dr. H. L. Brose, 488; Rays, Deflexion of, Prof. O. Stern, 727; Structure, Order Number, Excess Weight, and, G. Piccardi, 691; Structures, 419; Theory and Wave Mechanics, Prof. N. Bohr, 262; The Progress of, Dr. A. C. Crehore, 419; Weights of Isotopic Radio Elements and the Velocity of the α-rays which they emit, The Relation between the, G. Fournier, 730
Atoms, Energy Levels of, The Effect of Intense Light on the, Prof. A. E. Ruark, 389
Aurora of October 15, 1926, The, in Norway and Sounds associated with it, H. S. Jelstrup; Prof. C. Stormer, 45
Auroral: Green Line 5577, The, Dr. D. A. Keys, 162; Spectrum, Second Green Line of the, Spectrographic Observations of the, Prof. L. Vegard, 349; Spectrographic Observations of the Second Green Line of the, Lord Rayleigh, 525
Austral or Tubuai Islands, Southern Pacific, The Geology of the, L. J. Chubb, 261; The Petrography of the, W. Campbell Smith and L. J. Chubb, with chemical analyses by E. D. Mountain, 261
Australia, Magnetic Observations in, 508; Rainfall in, 615; The Flora of (No. 32), Prof. A. J. Ewart and L. R. Kerr, 35; No. 33, Prof. A. J. Ewart and Phyllis Jarrett, 838
Australian Coleoptera, New, with notes on some previously described species, Part III., F. E. Wilson, 514; Curculionidæ of the subfamily Gonipterides, A. M. Lea, 838; Diptera, Notes on (ix.), J. R. Malloch, 107; No. x., J. R. Malloch, 947; Marine Algæ, Notes on, A. H. S. Lucas (iii.), 263; Robberflies of the Cerdistus-Neoitamus Complex (Diptera-Asilidæ), A Reclassification of the, G. H. Hardy, 263; Rocks, The, Analyses of, M. Aurousseau, 263; Stone Implements, A. S. Kenyon, 939; Syrphidæ (Diptera), Revision of, Part II., E. W. Ferguson, 107
Australasia, Gasteromycetes of, G. H. Cunningham (vi.), 263
Australasian: Association for the Advancement of Science, Perth meeting of the, 28; officers for the Hobart meeting, 649
Autoxidation and Anti-oxygen Action (xxi.), C. Moureu, C. Dufraisse, and R. Chaux, 513

β-ray Spectra of Radium B and Radium C, The Relative Intensities of the Groups in the Magnetic, C. D. Ellis and W. A. Wooster, 301
β-rays: The Continuous Spectrum of, Dr. C. D. Ellis and W. A. Wooster, 563; The Photographic Action of, C. D. Ellis and W. A. Wooster, 301
Bacteriological Examination of Food and Water, The, W. G. Savage, 34
Bacteriology and Immunology, Laboratory Outlines in, Prof. J. F. Norton and Prof. I. S. Falk, Mar. 19, Suppt., 17
Bacterium typhi in Milk, Behaviour of, G. Gorini, 107
Baffin Island, an expedition to, led by G. P. Putnam, 865
Bakerian Lecture, The, Dr. F. W. Aston, 945
Ballistics: Dynamics and, 485; Exterior, New Methods in, Prof. F. R. Moulton, 485
Balmer Lines: Fine Structure of, Intensity Distribution in the, G. E. Harrison, 393; The Enlargement of the, by the Inter-molecular Electric Field, Mlle. M. Hanot, 413
Bankfield Museum, Halifax, Report of the, 648
Barium and Radium Chromates, Fractional Precipitation of, Henderson and Kracek, 796
Bastardierung betrachtet, Evolution im Lichte der, Dr. J. P. Lotsy. Aus dem Englischen übersetzt von H. N. Kooiman, Mar. 5, Suppt., 4
Bateson, Dr. W., an appreciation of, 828
Beam Wireless Communication with Australia, Progress of, 402
Beams of Moving Charged Particles, The Analysis of, by a Magnetic Field, W. A. Wooster, 477
Bedford College for Women, laying of foundation stone of a new wing, 935
Beeswax, Origin of the Coloration of, and the Composition of Propolis, G. F. Jaubert, 910
Benn's Sixpenny Library, 827
Benzene: Derivatives, The Synthesis of, S. C. Bate, 520; Magnetic Double Refraction of, The Constant of, Prof. C. V. Raman and K. S. Krishnan, 513
Bermuda, The proposed New Biological Station in, Prof. H. W. Rand, 143
Beryllium: Chloride, The Preparation of, C. Matignon and M. Piettre, 730; Oxidation of, The Heat of, C. Matignon and Mlle. G. Marchal, 730; The Reducing Properties of, C. Matignon and Mlle. G. Marchal, 658
Bibliographical Bulletin of the Eastern Section of the Seismological Society of America, 648
Bibliography, Scientific Method in, 417
Bielid Meteor Showers, The, W. J. Fisher, 539
Biochemie des Menschen und der Tiere seit 1914, Bearbeitet von Dr. F. Haurowitz, 283
Biogéographie, The Société de, 291
Biological: Classification, Dr. F. A. Bather, 329; Fact and Theory, J. T. Cunningham, Dr. F. H. A. Marshall, 568; Prof. C. Walker, 161, 456, 814; J. B. S. Haldane, 456; E. Ashby, 457; Prof. J. S. Huxley, 159, 350, 639; Prof. J. Johnstone, 319; Prof. D. Noel Paton; Prof. E. W. MacBride, 160; Fluctuations: Laws of, Prof. V. Volterra, 622; The Periodicity of, Prof. V. Volterra, 910; *Reviews and Biological Proceedings of the Cambridge Philosophical Society*, Vol. 2, No. 2, 793
Biologie, Die anorganischen Grenzgebiete der (insbesondere der Kristallvergleich), Prof. H. Przibram, 738
Biologischen Arbeitsmethoden, Handbuch der, Herausgegeben von Prof. E. Abderhalden: Lief. 204. Abt. 9. Teil 1, Hälfte 2, Heft 2, 156; Lief. 199. Abt. 9. Teil 4, Heft 2, 523; Lief. 191. Abt. 2. Teil 2, Heft 2, Mar. 5, Suppt., 5; Lief. 205. Abt. 2. Teil 2, Heft 4, Mar. 5, Suppt., 6
Biology: Logic and Law in, Dr. P. Chalmers Mitchell. 748; Popular, 848

Biometrika. Vol. 18, Parts I. and II., 40
Bird: Flight, Prof. F. Wood Jones, 31; Malaria, Asexual Reproduction without Loss of Vitality in the Organism of, Prof. R. W. Hegner, 65; Migration, Factors of, Prof. W. Rowan, 405; Sanctuaries in the Royal Parks of Scotland, Report upon, 611
Birds: and their Attributes, Dr. G. M. Allen, Mar. 5, Suppt., 2; Migration and Reproductive Rhythm in, Prof. W. Rowan, 351; of Ecuador, 336; On the Relation between Egg-weight and Body-weight in, Prof. J. S. Huxley, 513
Birmingham University: H. Munro Fox appointed professor of zoology; C. G. C. Chesters appointed assistant lecturer in botany, 32; Dr. I. de Burgh Daly appointed professor of physiology; impending conferment of honorary doctorates, 875
Bismuth: The Action of, on Hæmorragic Icterus, R. Sazerac, H. Nakamura, and Mme. M. Kitchevatz, 478; Wires, Cycles of Elastic Hysteresis in, B. Nannei, 106
Black Sea, The Perforating Algæ of the, G. Nadson, 730
Blair Duguid, near Alland[illegible] N.S.W., On the Hypersthene-andesite of, W. R. Browne and H. P. White, 303
Bohr Model, The, and the Supposed Coloration of the Ions, G. Magnanini, 374
Bohr's Theory, A Noteworthy Deduction from, N. Siracusano, 623
Boiler Plates, The Embrittlement of, S. W. Parr and F. G. Straub, 686
Books: and a Superlative, 453; published in the British Islands in 1926, 63; The Best, W. Swan Sonnenschein. Third edition. Part IV., 453
Boots Pure Drug Company, Ltd., Dr. F. L. Pyman appointed head of the research laboratories of, 612
Borax, On the Volatility of, Prof. I. M. Kolthoff, 425
Boron Trichloride, Density of, Briscoe, Robinson, and Smith, 727
Boschiman Hottentots, The Cranial Capacity of the, E. Pittard, 622; Weight of the Skull and of the Encephalon of the, E. Pittard, 767
Botanical Society of America, election of Prof. H. H. Bartlett as president, 171
Botany: and Hydrology, O. E. Meinzer, 254; A Practical Introduction to the Study of, Sir J. B. Farmer and Dr. H. Chaudhuri. New edition, Mar. 19, Suppt., 10; Elementary, an Introduction to the Study of Plant Life, Dr. W. Watson, Mar. 19, Suppt., 10; General, with special reference to its Economic Aspects, Dr. C. S. Gager; with three chapters on Heredity and Variation in Plants, by Dr. O. E. White, 742
Botrytis attacking Narcissus, An Unusual Species of, W. J. Dowson, 33
Bovine Foetus, Oxidising and Hæmatogenic Power of, Prof. A. Pugliese, 616
Boyle's Experimental Notes on the Mechanical Origin of Electricity, etc., 433
Brahmanism in Bengal, M. M. Chatterji, 146
Brass: Aluminium, and its Alloys, The Gases in, L. Guillet and A. Roux, 658; The Penetration of, by Tin and Solder, H. J. Miller, 584
Brassica nigra, The Various Soluble Ferments contained in, A. Astruc and M. Mousseron, 305
Brewing: and Malting, Technical Terms in, S. K. Thorpe, 438; in Babylon and Egypt, Dr. E. Huber, 404
Brighter Biochemistry, No. 4, 866
Bristol: Museum, report of the, 291; University, Dr. W. E. Garner appointed professor of physical chemistry; Dr. Morris W. Travers, reader in applied physical chemistry, and Dr. J. E. Lennard-Jones, professor of theoretical physics; Dr. H. W. B. Skinner, a Henry Herbert Wills research fellow in physics, 544
British: Aphides, 115; Architecture, Modern, Exhibition of, 680; Association: Preliminary Programme of the Leeds meeting of the, 723; Sir William Bragg nominated as president of the Glasgow meeting in 1928, 436; B.C., Adoption of Kilocycle Figures, 899; Chemical Abstracts. Index 1926, 805; Colonial Empire Conference, Speech to the, Mr. Amery, 755; Cotton Industry Research Association, Dr. R. H. Pickard appointed director of the, 679; Electrical and Allied Industries Research Association, annual report of the, 290; Empire: Minerals and Metals of the, 625; Research throughout the, Co-operation in, 661; Engineering Standards Association. Publication No. 205, 1926: British Standard Glossary of Terms used in Electrical Engineering, 230; Geophysical Observatories, The Work of the, Dr. A. Crichton Mitchell, 663; Honduras: Explorations in, Dr. T. W. Gann, 536; Forest Administration in, 257; Industries Fair, The, 371; Journal Photographic Almanac and Photographer's Daily Companion, The, 1927, edited by G. E. Brown, 488; Locomotives, The First, of the St. Etienne-Lyon Railway, Achard, 402; Mosquito Control Institute, The, 586; Museum: Copies of Frescoes from Theban Tombs in the, 793; (Natural History): additions to the, 170; retirement of Sir Sidney Harmer, 246; Dr. W. D. Lang appointed a deputy keeper in the Department of Geology, 330; acquisitions by the, 365; C. Tate Regan appointed director, and Dr. W. T. Calman keeper of zoology, 398; purchases for the Department of Zoology, 537; post-cards of the, 613, 866; recent acquisitions at the, 826; Catalogue of Cainozoic Plants in the Department of Geology. Vol. 1: The Bembridge Flora, Eleanor Mary Reid and Marjorie Elizabeth Jane Chandler; with a section on the Charophyta, by J. Groves, 887; Non-Ferrous Metals Research Association: exhibit of the, at the Science Museum, 470; report of the, 864; Optical Science and Industry, 383; Patent: Grants, Early, A. Gomme, 494; System, appointment of a committee upon the, 610; Photographic Research Association, report of the, 136; Plants, Some Interesting, C. E. Salmon, 104; Railways of 1825 as seen by Marc Seguin, Seguin, 402; Rainfall, 1925, 232; Science Guild, annual meeting of the, 825; Settlement in the Dominions Overseas, 693; Christopher Turnor; The Writer of the Article, 890; Spas and Climatic Health Resorts, A Guide to, 293
Bromme, The Spark Spectra of, L. and E. Bloch, 373
Bronze Age Tumulus at Dunstable, A, Prof. G. Elliot Smith, 404
Brown, Horace, Memorial Lecture, The, Prof. H. E. Armstrong, 399
Brownian Movement, The, of a Galvanometer Coil and the Influence of the Temperature of the Outer Circuit, L. S. Ornstein, H. C. Burger, J. Taylor, and W. Clarkson, 802
Bruce gold medal of the Astronomical Society of the Pacific, award of the, to Prof. H. H. Turner, 402
Brucine, The Phylactic Action of, towards Strychnine, A. Goris and L. Lachaise, 879
Brussels Institute of Bibliography, The Decimal Classification of Melvil Dewey and its Extension by the, Dr. S. C. Bradford, 429
Bryant and May Museum of Fire-making Appliances. The, Catalogue of the Exhibits, compiled with an Introduction and Notes, by Miller Christy, 777
Bunsen Society, Annual Conference of the, 936
Burma: The Serpentine Belt of, H. L. Chhibber, 726; University, gift by the Burmah Oil Company, 908
Business Climate, The, Lord Riddell, 411
Butters and Margarines, A Rapid Method for the Sorting of, C. H. Manley, 34

Caballero's Technique for Mounting Diatom and other Type Slides, C. Tierney, 70
Cables, 33,000-volt, P. Dunsheath, [illegible]10
Cacao Butter Substitutes and their Detection, A. W. Knapp, J. E. Moss, and A. Melley, 546
Cæsium Eosinate, Some Physico-chemical Properties of, R. Delaplace and N. Marinesco, 146
Cainozoic Plants, 887
Calcite and Crystalline Sodium Nitrate, Certain Elastic Constants of, S. Chapman and A. E. Ludlam, 877
Calcium: and Zinc, The Paramagnetism of the Elements between, A. Carrelli, [illegible]14; Chromosphere, The Light Intensity of the, P. A. Taylor, 945; in Aluminium containing Silicon, J. D. Grogan, 685; The Influence of, on Aluminium containing Silicon, J. D. Grogan and P. G. Ward, 585
Calcul différentiel et intégral, Exercices de, par l'Abbé Potron. Premier volume, Mar. 5, Suppt., 8

Calcutta School of Tropical Medicine, Work of the, 69
Calendar of Discovery and Invention, 300, 337, 372, 412, 444, 477, 512, 584, 620, 656, 689, 729, 765, 800, 835, 876, 908, 944
Calendar Reform, W. B. Cotsworth, 613
California University, conferment of a doctorate on Prof. H. H. Turner, 827
Californian Indians, Early Records of, E. W. Gifford and W. E. Schenk, 138
Cambrian Area of Comley (Shropshire), The Stratigraphy and Geological Structure of the, E. S. Cobbold, 620
Cambridge University: Prof. A. E. Taylor appointed Leslie Stephen lecturer for 1927; H. Claye appointed an assistant registrary, 69; A. R. Clapham appointed Frank Smart University student in botany, 143; bequest by M. E. Lange, 179; bequest by Prof. E. G. Browne; award of the Gordon Wigan prize to W. A. Waters; proposed regulations for the new professorship in political science, 258; Prof. J. A. Fleming, Prof. G. F. Stout, and Prof. A. E. H. Love elected honorary fellows of St. John's College; A. Amos re-appointed director of the University farm; report of the Faculty Board of Archæology and Anthropology, 411; S. Goldstein and W. V. D. Hodge awarded Smith's prizes; D. Burnett and C. A. Meredith awarded Rayleigh prizes; the Disney professorship of archæology; proposal to appoint H. Quinney as an assistant in experimental research in the engineering department, 444; P. Hall elected a fellow of King's College; A. F. H. Ward elected Amy Mary Preston Read scholar; report of the University Appointments Board, 476; Field-Marshal Sir William Birdwood elected an honorary fellow of Peterhouse; R. O. Redman elected to the Sheepshanks exhibition in astronomy at Trinity College, 546; Appointments Board of, The work of the, 722; H. E. Tunnicliffe appointed University demonstrator in physiology, 729; bequest by Prof. A. W. Scott; J. E. Purvis re-appointed University lecturer in chemistry; A. Hopkinson re-appointed demonstrator of anatomy, 764; Dr. G. F. C. Searle re-appointed University lecturer in experimental physics, and C. Warburton demonstrator in medical entomology, 799; and K. W. Fair appointed demonstrator in agricultural physiology; W. A. Wooster demonstrator in mineralogy, 835; proposed new lectureships and a special animal house, 835; F. Debenham appointed reader in geography; T. G. Bedford lecturer in physics; Dr. E. M'Kenzie Taylor lecturer in agricultural chemistry; Dr. H. E. Woodman demonstrator in agricultural chemistry, 835; Rev. G. A. Weekes re-elected Vice-Chancellor; L. A. Pars and H. A. Newman elected University lecturers in mathematics, 875; H. E. Woodward appointed University lecturer in engineering; Dr. C. M. Yonge elected Balfour student; Pendulum Observations on Sabine Island, G. Manley, 907; C. E. Maitland awarded the John Bernard Seely prize; E. B. Worthington awarded a grant from the Balfour Fund, 943; E. J. H. Corner and A. L. Bennett awarded Frank Smart prizes; C. S. M'Leod awarded the Tyson medal; J. Hargreaves awarded the Mayhew prize; J. N. Goodier awarded the Rex Moir and the Ricardo prizes, 943; A. S. Besicovitch appointed lecturer in mathematics; H. W. Florey Huddersfield lecturer in special pathology; R. V. Sayce lecturer in material culture and physical anthropology; Dr. J. Chadwick lecturer in physics and assistant director of radio-active research; F. W. Shotton elected to the Harkness scholarship in geology, 943
Canada: and Newfoundland, Judgment in the Boundary Dispute between, 398; The Transportation of Bisons in, 95; Western, Iron Ore in, G. A. Young and W. L. Uglow, 796
Cancer: Research in Sydney on, 649; The Origin and Evolution of, J. Amar, 878
Canine Distemper, The Cause of, 62
Capacitance Bridge, A, of Wide Range and a New Inductometer, A. Campbell, 221
Cape to Cairo Flight of the R.A.F. in 1925, Account of the, 96
Carbohydrate Metabolism and Insulin, Prof. J. J. R. Macleod; Prof. H. MacLean, 220
Carbon: Assimilation, Prof. W. Stiles, 406; Dioxide: Gas, Action of Magnetic Fields on the Refractive Index of, E. T. S. Appleyard, 353; Measuring Instrument, A, based on Sound Velocity Measurement, Dr. Ezer Griffiths, 836; The Chemical Yield in the Decomposition of, under Small Pressure by the Condensed Spark, P. Jolibois, H. Lefebvre, and P. Montagne, 546; The Dissociation of, at High Temperatures, R. W. Fenning and H. T. Tizard, 877; The Influence of Some Organic Substances on the Velocity of Absorption of, by Solutions of Neutral Sodium Carbonate, P. Riou and P. Cartier, 448; Monoxide: Molecule of, Structure of the, F. L. Mohler and P. D. Foote, 369; Poisoning in the Absence of Hæmoglobin, J. B. S. Haldane, 35[illegible]; Prof. H. E. Armstrong, 460; Prof. P. F. Frankland, 491; Steel, Tetragonal Structure of, Prof. N. Seljakow, J. Kurdumoff, and N. Goodtzov, 494
Carbonate Crystals, Some Theoretical Determinations of the Structure of, Part I., J. E. Lennard-Jones and B. M. Dent, 181
Carboniferous Lamellibranchs, New, and Notes on other Forms, J. W. Jackson, 766
Carcinus mænas, Observations and Experiments on, Prof. W. C. McIntosh, reprint of, 402
Cardinal Function Interpolation, On the Consistency of, W. L. Ferrar, 946
Carnegie: Institution, Department of Terrestrial Magnetism, Annual Report, 867; Trust for the Universities of Scotland, Activities of the, 619; United Kingdom Trust, annual report for 1926, 902
Castor, The Distant Companion of, Prof. H. N. Russell, 25
Catalytic Combustion, Studies upon, Prof. W. A. Bone and A. Forshaw, Pt. V., 259
Cathode Rays, Diffraction of, by a Thin Film, Prof. G. P. Thomson and A. Reid, 890
Cattle, The Maintenance Requirements of, on Different Kinds of Rations and at Different Rates of Production, Prof. J. Wilson, 586
Cavendish: Laboratory, Clerk Maxwell and the, Sir Oliver Lodge, 46; Society, Post-Prandial Proceedings of the, sixth edition, 233
Cell Division, 556
Cellulose: in the Soil, The Degradation of, S. Winogradsky, 546; Paints, W. F. Starkey, 727
Cement, Concrete, and Bricks, A. B. Searle, 455
Centenaries of the Present Year, Notable, Prof. H. J. Spooner, 184
Cetacea stranded on the British Coasts from 1913 to 1926, Report on, Sir Sidney F. Harmer, 6[illegible]7
Ceylon, The Fisheries of, Dr. J. Pearson, 68
Chætopterus variopedatus, The Control of the Beat of the Fan Segments in, N. J. Berrill, 564
Channel Islands, Archæology of the, Dr. R. R. Marett, 20
Charcoal: Heats of Adsorption on, F. G. Keyes and M. J. Marshall, 406; The Expansion of, on Sorption of Carbon Dioxide, F. T. Meehan, 545
Charophyta: from Madagascar, J. Groves, 945; The Alleged Larvicidal Qualities of, T. B. Blow, 945
Cheilanthes vellea, The Anatomy of, Miss May M. Williams, 947
Chemical: Abstracts, British, Index 1926, 805; Affinity, Calculation of, on the Basis of Entropy (II.), G. Bozza and G. Devoto, 767; Age Year Book, Diary and Directory, The, 1927, 275; Analysis: A Student's Manual of, Qualitative and Quantitative, Prof. J. F. Thorpe and Prof. M. A. Whiteley. Reissue with Appendix on New Methods of Organic Analysis, by H. ter Meulen and J. Heslinga, Mar. 19, Suppt., 16; A Systematic Qualitative, a Theoretical and Practical Study of Analytical Reactions of the More Common Ions of Inorganic Substances, Prof. G. W. Sears. Second edition, Mar. 19, Suppt., 16; Change in Gaseous Systems, The Kinetics of, C. N. Hinshelwood, 771; Engineers, Transactions of the Institution of. Vol. 3, 1925, 275; Industry and Technical Institutions, W. J. U. Woolcock, 942; Laboratory, The First Public, in England, Dr. R. T. Gunther, 492; -plant Operation, Control of, D. Ryder and T. C.

Finlayson, 23; Research in Great Britain, Imperial Chemical Industries and, 290; Society, annual general meeting of the, 504
Chemie, Geschichte der, Studien zur, Festgabe Edmund O. v. Lippmann zum siebzigsten Geburtstage, 451
Chemiker-Zeitung, Jubilee number of the, 210
Chemist and Philosopher, Prof. A. Findlay, 228
Chemistry: and Recent Progress in Medicine, Prof. J. Stieglitz, 156; Classified Problems in, D. B. Briggs, 668; Colloid, Practical, Prof. Wo. Ostwald, with the collaboration of Dr. P. Wolski and Dr. A. Kuhn. Translated by Dr. I. N. Kugelmass and Dr. T. K. Cleveland, 386; General, Exercises in, and Qualitative Analysis, Prof. H. G. Deming and Prof. S. B. Arenson. Second edition, 702; Historical, Research in, Prof. J. Read, 451; Inorganic: General, Prof. M. C. Sneed, Mar. 19, Suppt., 15; A Junior, R. H. Spear. Second edition, 702; A Text-book of, Prof. F. Ephraim. English edition by P. C. L. Thorne, 7; A Text-book of, Edited by Dr. J. Newton Friend. Vol. 3, Part 2; Vol. 7, Part 3, Mar. [illegible] Suppt., 16; in the Middle School, The Teaching of, Miss R. Stern, 619; of Rhythmic Actions, The, Prof. I. Masson, 267; Organic: A Text-book of, Historical, Structural, and Economic, Prof. J. Read, 79; A Laboratory Book of Elementary, Prof. A. Lowy and W. E. Baldwin, 777; A Text-book of, Prof. J. Schmidt. English edition by Dr. H. G. Rule, 384; Theoretical, Dr. F. Arnall and F. W. Hodges. Part I., Mar. 19, Suppt., 16; Synthetic Organic, The Use of Solvents in, Prof. D. W. MacArdle, 520; The Growth of the Profession of, during the Past Half-century (1877–1927), A. Chaston Chapman, 913
Chemists, Organisation and Registration of, 913
Chesapeake Bay, The Microplankton of, J. J. Wolfe, B. Cunningham, and others, 439

Ciliated Protozoa and Contractility, Prof. A. Pensa, 439
Ciona intestinalis (L.), History of the Cytoplasmic Inclusions of the Egg of, during Oogenesis and Fertilisation, L. A. Harvey, 220
Citrus Growing in South Africa, R. A. Davis, 776
Civil: Engineering, Specifications and Quantities, Dr. G. S. Coleman and G. M. Flood, 701; Engineers, Institution of, awards of the, 725
Classical Education, The Advantages of a, G. H. Bonner, 1[illegible]
Clay, The Anomalous Flocculation of, Dr. A. F. Joseph and H. B. Oakley, 673
Cleistopora Zone, The Index Fossil of the, L. B. Smyth, 658
Clementia, The Genus, in American Tertiaries, W. P. Woodring, 684
Clifton College, New Science School at: opening of the, 863, 871
Climate and Animal Evolution, Prof. E. C. Case, 940
Clinical Laboratory Procedure: A Manual of, for the Use of the General Practitioner, Dr. K. A. Kilduffe, Mar. 19, Suppt., 17
Cloudiness in Malt Liquors, The Causes and Correction of, J. Ross-Mackenzie, 802
Clydesdale Breed of Horses, Rôle of Interbreeding in the Development of the, A. Calder, 621
Clypeina jurassica in the Portlandian at Various Points of the Southern Jura, The Presence of, J. Favre, 767
Coal: Analyses of, 870; Carbonisation: Dr. C. H. Lander, 508; Retorts, 653; Dusts, Inflammability of, 832; Getting out the, Stripping, Underground Mining, Loading Machines, Roof Support, Compiled by F. H. Kneeland, 231; Radiographic Examination of, Kemp and Thompson, 296; Sections, The Preparation and Examination of, J. Lomax, 909; Workings, The Support of, 653
Coalfields of Wales, Dr. F. J. North, 581
Coastal Currents along the Pacific Coast of the United States, H. A. Marmer, 443
Cobalt, A New Transformation of, H. Masumoto, 255
Cocaine, Prof. E. Poulsson, 174
Coconut Moths, A Tachinid Parasite of the Larvae of, B. A. R. Gater, 651
Coke, Some Properties of, Prof. J. W. Cobb, 751
Collembola from Spitsbergen, Further Records of, Dr. G. H. Carpenter, 418
Colliery Working: The Use of Power in, a Treatise on Mining Costs and Machinery Designs and Management, J. Kersopp, Mar. 19, Suppt., 19
Colloid Theory, Some Recent Advances in, D. C. Henry, 446
Colloidal: Chemistry, New Conceptions in, Prof. H. Freundlich, 488; Solutions: Rigidity and other Anomalies in, E. Hatschek, 469, 857; Surface Equilibria of, Advantages of the Ring Method for the Study of the, Dr. P. Lecomte du Noüy, 598
Colloids, Biological and Organic, Surface Equilibria of, Dr. P. Lecomte du Noüy, 528
Colonial: Conference, a forthcoming, 574; Scientific and Research Services, The Colonial Office Conference and, 824
Coloured Light, The After-images of, Miss W. M. Smith, 621
Colours shown during the Oxidation of Metallic Copper, The Cause of the, Dr. F. H. Constable, 877
Columbus, The Landfall of, Lieut.-Commdr. R. T. Gould, 368
Comas Sola quickly moving Asteroid, The, 293
Comet: A New, 1927*d*, 437; Comas Sola, 64; Grigg-Skjellerup, 539; New, W. F. Gale, 903; Pons-Winnecke, Return of the, 403
Comets: 137, 173, 212, 252, 471, 505, 578, 650, 759, 938; and the Law of Gravitation, Dr. A. C. D. Crommelin, 464; The Romance of, Mary Proctor, Mar. 19, Suppt., 14
Commercial Iron, Copper, and Zinc, The Inalterability of, by Liquid Hydrogen Sulphide, J. B. Fournier and Fritsch-Lang, 947
Commonwealth: Council for Scientific and Industrial Research, Policy of the, 246; Fund Fellowships, appointments to, 800
Compass Variation in Canada, W. H. Herbert, 405
Compression, Regions of, Dr. J. W. Evans, 55
Computing Machines, Dr. L. J. Comrie, 870
Conglomerates of the Enville Series of the Warwickshire Coalfield, The, F. W. Shotton, 836
Copper: Impurities on, The Effects of, Part V., D. Hanson and Grace W. Ford, 584; Influence of Impurities on, Prof. D. Hanson and others, 728
Cork Formation, Relation of, to the Endodermis in the Shoot of the Dicotyledon, Prof. J. H. Priestley, 35
Cornell University, gift to, for a professorship in forest soils, 583
Correlation Coefficients and the Theory of Mental Abilities, J. R. Thompson, 705

CORRESPONDENCE.

α-Rays and β-Rays through Matter, The Passage of, Dr. E. J. Williams, 489
Académie des Sciences, Paris, Members and Correspondants of the, L., 459

Adrenal Cortex, The Chemistry of the, Dr. A. v. Szent-Gyorgyi, 782
Agriculture, The Beginning of, Prof. G. Elliot Smith, 81 ; Prof. J. Percival, 157 ; H. J. E. Peake, 158
Alchemy, Chinese, Prof. J. R. Partington, 11
Algebraic Equations, Numerical Solution of, Dr. H. Jeffreys, 565
Alloys, Hardness of, A. Mallock, 669
Aluminium, Surface Film of, H. Sutton and J. W. W. Willstrop, 673, 925 ; W. H. Withey, 924
Amines, Liquid and Vapour, Absorption Bands of, E. O. Salant, 926
Amphipneustes, Dr. F. A. Bather, 460
Anisogeny, A suggested Interpretation of certain Cases of, R. J. Chittenden and Caroline Pellew, 11
Antarctic, Two-way Communication with the, W. H. Brown, 238
'Antiknocks,' The Action of, A. Egerton and S. F. Gates, 427
Arctic Peat in Ireland, An, A. W. Stelfox, 781
Argon, The Geissler Discharge in, Dr. K. G. Emeléus and N. L. Harris, 602
Artists, Distinctive Colour Senses of, Sir Arthur Schuster, 783
Aspergillus niger, Formation of Organic Acids from Sugars by, Dr. F. Challenger, V. Subramaniam, and T. K. Walker, 674
Atmospheric : Circulation, Dr. H. Jeffreys, 194 ; Electricity, Dr. L. A. Bauer, 457 ; Dr. C. Chree, 458
Atoms, Energy Levels of, The Effect of Intense Light on the, Prof. A. E. Ruark, 389
Aurora of October 15, 1926, The, in Norway and Sounds associated with it, H. S. Jelstrup, 45 ; Prof. C. Stormer, 45
Auroral : Green Line 5577, The, Dr. D. A. Keys, 162 ; Spectrum, Second Green Line of the, Spectrographic Observations of the, Prof. L. Vegard, 349 ; Lord Rayleigh, 525
β-rays, The Continuous Spectrum of, Dr. C. D. Ellis and W. A. Wooster, 563
Balmer Lines of Hydrogen, Fine Structure of the, Prof. N. A. Kent, L. B. Taylor, and H. Pearson, 163
Biological Fact and Theory, Prof. D. Noel Paton, 159 ; J. T. Cunningham, 563 ; Dr. F. H. A. Marshall, 563 ; Prof. J. S. Huxley, 159, 350, 639 ; Prof. E. W. MacBride, 160 ; Prof. C. Walker, 161, 456, 814 ; Prof. J. Johnstone, 319 ; J. B. S. Haldane, 456 ; E. Ashby, 457
Borax, On the Volatility of, Prof. I. M. Kolthoff, 425
British : Patent Grants, Early, A. Gomme, 494 ; Settlement in the Dominions Overseas, Christopher Turnor, 890 ; The Writer of the Article, 891
Carbon : Dioxide Gas, Refractive Index of, Action of Magnetic Fields on the, E. T. S. Appleyard, 353 ; Monoxide : and Light, Influence of, on Indophenol Oxidase of Yeast Cells, D. Keilin, 670 ; J. B. S. Haldane, 352 ; Poisoning in the Absence of Hæmoglobin, Prof. H. E. Armstrong, 460 ; Prof. P. F. Frankland, 491 ; Steel, Tetragonal Structure of, Prof. N. Seljakow, J. Kurdumoff, and N. Goodtzov, 494
Cathode Rays, Diffraction of, by a Thin Film, Prof. G. P. Thomson and A. Reid, 890
Chætopterus variopedatus, The Control of the Beat of the Fan Segments in, N. J. Berrill, 564
Chinese : Alchemy, Prof. J. R. Partington, 11 ; Kala-azar, Sandflies and, E. Hindle and Major W. S. Patton, 460
Chromosome Groups, The Nomenclature of, Dr. J. Belling, 926
Clay, The Anomalous Flocculation of, Dr. A. F. Joseph and H. B. Oakley, 673
Colloidal Solutions, Surface Equilibria of, Advantages of the Ring Method for the Study of the, Dr. P. Lecomte du Noüy, 598
Convection of Heat in Fluid Flow through Tubes, H. F. P. Purday, 527
Correlation Coefficients and the Theory of Mental Abilities, J. R. Thompson, 705
Cosmic Evolution, The Course of, Sir Oliver Lodge, 387
Cotton : A Mutant in, G. L. Kottur, 747 ; Occurrence of Branched Hairs in, and upon *Gossypium Stocksii*, W. Youngman and S. S. Pande, 745 ; Egyptian Branched Lint Hairs in, The Occurrence of, N. W. Barritt, 392
Coup-de-Poing, Prof. W. J. Sollas, 490 ; H. Balfour, 490
Crystals, Twin Metallic, The Formation of, G. D. Preston, 600
Dactylis glomerata (Cocksfoot), The Chromosome Number in, J. G. Davies, 236
Darwinism Dead ? Is, H. Belloc, 277, 427, 526 ; Sir Arthur Keith, 277, 526
Dawson (W. Bell), Icebergs in relation to Water-Temperature, 236
Day, Length of the, Changes in the, Dr. J. K. Fotheringham, 318
Dielectric Bodies in Electrostatic Fields, Rotation of, Dr. S. W. Richardson, 238 ; C. Record, 319 ; G. L. Addenbrooke, 389 ; A. W. Simon and J. M. Cage, 816
Dilatancy, The Property of, L. B. Tuckerman, 602
Divining Rod, Behind the, Prof. W. J. Sollas, 458, 565 ; Dr. H. Mill, 458 ; Dr. M. Culpin, 783
Double-Image Effect in Transparent Microscopic Spheres, H. S. Patterson and Prof. R. Whytlaw-Gray, 199
Dowsing or Divining Rod, The, Sir Oliver Lodge, 387
Dug-out Canoe in Algoa Bay, [illegible] R. N. Rudmose Brown ; G. S. Laird Clowes, 856
Dyes, Adsorption of, to Silver Halides : a Correction, Dr. S. E. Sheppard, 281
Earth's Surface Structure, The Origin of the, Prof. J. Joly and Dr. J. H. J. Poole, 524, 674
Effectivity ? Efficiency or, Prof. E. P. Cathcart, 599
Electric : Cell, A Useful, Prof. S. L. Jindal, 639 ; Wave Phenomena, A Quantum Relation in Large Scale, T. L. Eckersley, 234
Electricity in Conductors, Thermal Agitation of, J. B. Johnson, 50
Electromagnetic Waves, Refraction of, round the Earth's Surface, J. S. McPetrie and R. M. Wilmotte, 317
Electron 'Reflection' *in Vacuo*, D. Brown and Prof. R. Whiddington, 427
Electrons : Spinning, and Protons, Prof. H. S. Allen, 237 ; The Scattering of, by a Single Crystal of Nickel, C. Davisson and L. H. Germer, 558
Existence, The Continuity of, D. B. Mair, 199
Fatty Acids : Different Modifications of. X-ray Evidence for the Existence of, G. M. de Boer, 40 ; Polymorphism of, X-ray Investigation of the, G. M. de Boer, 634
Fatuoids in Cultivated Oats, The Origin of, C. L. Huskins, 49
Fayum Lakes, The, Sir Flinders Petrie, 238
Ferromagnetic Substances, The Intrinsic Fields in, J. Dorfman, 353
First Public Chemical Laboratory in England, The, Dr. R. T. Gunther, 492
Flame Speeds : The Law of, Dr. W. Payman and Prof. R. V. Wheeler, 747, 779 ; Prof. W. A. Bone, 922 ; The Supposed Law of, A. G. White, 51, 674 ; Dr. W. Payman and Prof. R. V. Wheeler, 238
Flint Surfaces, The Microscopical Examination of, J. Reid Moir, 560 ; W. J. Lewis Abbott, 747
Florentium or Illinium ? Prof. L. Rolla and L. Fernandes, 637
Flowering Plants, Multiple Chromosomes and Reduction Division in, Dr. J. Belling, 122
Fluorine, Arc Spectrum of, The Double Normal State of the, Prof. H. Dingle, 86
Forestry Institute, The Imperial, Prof. R. S. Troup ; The Writer of the Note, 197
γ-Ray Absorption, Temperature Coefficient of, L. Bastings, 51
Gallium in Flue Dust, H. Ramage, 783
Gamma Rays, The Scattering of, Dr. L. H. Clark, 121
Gammarus chevreuxi Sexton, Inheritance in, Mrs. E. W. Sexton and C. F. A. Pantin, 119
Gaseous : Mixture, Simultaneous Ionisation and Excitation by Foreign Ions in a, Prof. O. S. Duffendack and H. L. Smith, 743 ; Mixtures, The Pressure of, Dr. J. E. Lennard-Jones, 459
"Grammar of Science," Unauthorised Publication of, Prof. Karl Pearson, 926
Great Nebulæ, The Genesis of the, Dr. J. H. Jeans, 215
Gunfire, Audibility of, F. J. W. Whipple, 782
Hæmocyanin, Oxidation of, Colorimetric Determination of the, Prof. L. Hogben, 122
Hafnium, Persistent Lines of, M. Petersen, 352

Hardness: of Metals in Relation to Periodicity, S. A. Korff, 818; Stresses involved in Tests of, and a Table of the Comparative Hardness of Certain Metallic Elements, A. Mallock, 276
Haze, Dr. J. S. Owens, 561
Heat: Convection of, in Fluid Flow through Pipes, H. M. Martin, 672; through a Brick Wall, Transmission of, L. R. Ingersoll and J. Bardeen, 892
Helion? Helium or, Dr. J. Newton Friend, 199
Helium: Hydrogen into, The Transmutation of, Prof. F. Paneth, 706; or Helion? Dr. J. Newton Friend, 199
Hereditary Choice of Food-plants in the Lepidoptera and its Evolutionary Significance, E. Meyrick, 388; Dr. J. W. Heslop Harrison, 562
Higher Fatty Acids, The Polymorphism of, Dr. J. Thibaud, 852
Humic Matter, The Origin of, C. E. Marshall and H. J. Page, 393
Hyacinthus, Bivalents of, The Nodes at the Reduction Division in, Dr. J. Belling, 527
Hydrogen: Chloride Vapour, Ionisation in, H. A. Barton, 197; Fluoride, Ionisation Potential of, Prof. S. C. Biswas, 707; into Helium, The Transmutation of, Prof. F. Paneth, 706; Iodide, Photochemical Decomposition of, B. Lewis, 493; The Infra-Red Spectrum of, Dr. A. H. Poetker, 123
Hythe Skulls, The, Prof. F. G. Parsons, 893
Illinium, Prof. W. A. Noyes, 310
Imperial Forestry Institute, The, Prof. R. S. Troup; The Writer of the Note, 197
Indium in Tin, The Occurrence of, J. R. Green, 893
Industrial Revolution, The, E. W. Hulme, 671, 892; Miss Mabel C. Buer, 671; H. W. Dickinson, 818
Insects, Phytophagic or Biological Races in, W. H. Thorpe, 602; E. Meyrick, 762
Ionisation of a Fused Salt, The Coefficient of, Prof. T. M. Lowry, 564
Ions and Atoms or Molecules, Collections of the Second Kind between, Dr. H. D. Smyth, G. P. Harnwell, T. R. Hogness, and E. G. Lunn, 85
Iron Crystals, L. W. McKeehan, 705
Kala-azar, Sandflies and, Major H. E. Short, 80[illegible]
Kammerer's Water-bred Alytes, The Nuptial Pad of, W. C. Kiplinger; Prof. H. Przibram, 635; Prof. E. W. MacBride, 707
'Knock' Suppression, The Mechanism of, Prof. H. S. Taylor, 746
Lamp Filaments, Pathology of, Sir Oliver Lodge, 387
Laplace: The Brain of, Prof. Karl Pearson, 560; The Tomb of, Eng.-Capt. E. C. Smith, 493
Leguminosæ, 'Hard Seeds' in, C. J. Berkeley, 198
Leishmania sp. in *Phlebotomus papatasii*, The Behaviour of Cultures of, Dr. S. Adler and O. Theodor, 565
Lepidoptera, Melanism in the, and its Evolutionary Significance, Prof. W. J. Dakin; Dr. J. W. Heslop Harrison, 318
Lewes, George Henry, Sir E. Sharpey-Schafer, 281
Light Quanta, The Length of, Dr. G. Breit, 280
Lightning, Progressive, Dr. C. D. Perrine, 278, 816; Prof. C. V. Boys, 279, 816
Lilium longiflorum and its Varieties, An Important Virus Disease of, L. Ogilvie, 528
Limnæa peregra, The Origin of an Albino Mutation in, Prof. A. E. Boycott and C. Diver, 9
Limnoria, The Absence of a Cellulase in, Dr. C. M. Yonge, 855
Luciola gorhami, Origin of Yolk in the Eggs of, Prof. V. Nath and Dev Raj Mehta, 13
Lumbricus, The Oögenesis of, L. A. Harvey, 14
Magnetic: Double Refraction, Prof. C. V. Raman and J. Rama Krishna Rao, 528; Induction in Continuous Media, C. R. Burch and N. R. Davis, 353
Mawkin Canoe in Algoa Bay, A, F. W. FitzSimons, 746
Maxwell, Clerk, and the Cavendish Laboratory, Sir Oliver Lodge, 46
Melanism in the Lepidoptera and its Evolutionary Significance, Prof. W. J. Dakin; Dr. J. W. Heslop Harrison, 318
Memphis, The Floods at, S. R. K. Glanville, 813
Mental Abilities, Correlation Coefficients and the Theory of, J. R. Thompson, 705
Mercury: Absorption Spectrum of, Bands in the, Lord Rayleigh, 778; derived from Coal Tar, The Constitution of, Dr. F. W. Aston, 489, The Band Spectrum of, from the Excited Vapour, Lord Rayleigh, 387, 423; Vapour Trap, An Improved, G. I. Finch, 856
Metallic: Catalyst, A New Method of Measuring the Absolute Surface Area of a, Dr. F. H. Constable, 349; Crystals, Twin, The Formation of, L. W. McKeehan, 120, 392; Prof. H. C. H. Carpenter and S. Tamura, 121; Salt, Optically Active Complex, A Novel Type of, Dr. F. G. Mann and Sir W. J. Pope, 351; Single Crystals, Etch Planes in, H. H. Potter and W. Sucksmith, 924
Migration and Reproductive Rhythm in Birds, Prof. W. Rowan, 351
Mineral Compounds, Chemical Formulæ of, L. W. Tibyriçá; J. W. E., 815
Modified Scattered X-Radiation due to Super-Position, Prof. C. G. Barkla, 778
Molecular Beams, Intensities of, T. H. Johnson, 745
Money, The Mystery of, Prof. F. Soddy, 46; W. H. Coates, 47
Muscular Contraction, The Significance of Phosphorus in, P. and M. G. Eggleton, 194
Natural: History: Museums, The Development of, Dr. F. A. Bather; The Writer of the Article, 639, Museum, South Kensington, The Future of the, Sir E. Ray Lankester, 314; Selection, Larger Aspects of, Prof. T. D. A. Cockerell, 564
Neon: Ionised: Regularity in the Spectrum of, P. K. Kichlu, 671; (Ne II), The Spectrum of, T. L. de Bruin, 925; Spectrum, Hyperfine Structure in the, Dr. G. Hansen, 237
Newton's Moving Water Rings, White Spot with, Prof. J. Muir, 781
NH Compounds, The Spectra of, Dr. E. Hulthén and S. Nakamura, 235
Nitric Oxide, The β Bands of, F. A. Jenkins, H. A. Barton, and Dr. R. S. Mulliken, 118
Nitrogen: Active: Dr. R. C. Johnson, 9; Dr. E. J. B. Willey, 924; Ionisation Phenomena in, P. A. Constantinides; Lord Rayleigh, 163, Pentoxide, Decomposition of, Dr. R. G. W. Norrish, 123
Non-Magnetic Films of Iron, Nickel, and Cobalt, J. D. Hanawalt and L. R. Ingersoll, 234; Dr. L. C. Jackson, 426
Odours and Visual Imagery, Dr. J. H. Kenneth, 818
Oligochæte, A Polymorphic, Rev. Hilderic Friend, 281
Oxygen: and Nitric Oxide, The Theory of the Paramagnetism of, Prof. J. H. Van Vleck, 670; = 17.00, Prof. H. E. Armstrong, 51
Pauli's Exclusion Principle, Relation between the Reciprocal Impenetrability of Matter and, Prof. P. Ehrenfest, 196
Pearls, Structure of, C. Amirthalingam, 854
Phlebotomus papatasii, The Behaviour of Cultures of *Leishmania tropica*, *L. infantum*, and *L. brasiliense* in the Sandfly, Dr. S. Adler and O. Theodor, 48, 565
Photo-electric Polarimetry, Prof. H. von Halban, 86
Photo-electrons produced by Soft X-rays, The Energy of, E. Rudberg, 704
Photographic Plates, The Calibration of, F. S. Hogg and Cecilia H. Payne, 925
Pinholes in Photographic Negatives, Capt. C. J. P. Cave, 852
Plants, Excitation in, Transmission of, Sir J. C. Bose, 48
Polar Pressures, L. C. W. Bonacina, 124
Polyploids, The Behaviour of, C. D. Darlington, 390
Prehistoric Archæology in Yorkshire, O. G. S. Crawford, 494; T. Sheppard, 601
Primary Cell, A New Type of, D. R. Barber, 802
Prothetely in Insects, Dr. Hem Singh Pruthi, 301
Protons, Spinning Electrons and, Prof. H. S. Allen, 237
Quantum Theory: and Gravitational Relativity, Prof. N. Wiener and D. J. Struik, 853; Philosophical Foundations of, Dr. N. R. Campbell; Dr. P. Jordan, 770
Radcliffe Science Library, The, Oxford, Lord Cottesloe, 350; The Writer of the Notes, 351
Radiation: from the Earth, Experiments on Highly Penetrating, L. N. Bogoiavlensky and A. A. Lomakin, 525; Intensity, Measurement of, by Photographic Methods, Dr. E. A. Baker, 707

Radioactivity and the Heat of the Earth, Dr. R. W. Lawson, 277, 503; Dr. J. W. Evans, 424
Rain-drops, Distribution of Sizes among, Prof. J. J. Nolan and J. Enright, 922
Reciprocal Impenetrability of Matter, Relation between the, and Pauli's Exclusion Principle, Prof. P. Ehrenfest, 106, 602
Relativity and the Observer, Prof. H. Wildon Carr, 199
Research Associations, Financing of, R. W. Paul, 673
Resonance Radiation, A Source for, M. A. Tuve, 85
River Pollution and the Acidity of Natural Waters, W. J. M. Menzies, 638
Rock of Unknown Origin, A, from Glacial Gravel at Ipswich, J. Reid Moir, 50
Rocksalt, Refractive Index of, Effect of Temperature on the, Sir R. Robertson and Dr. J. J. Fox, 818
Rubber, Electro-deposition of, Dr. S. E. Sheppard, 303
Runge, Prof. Carl, Sir Oliver Lodge, 565
Sampling, A Convenient and Rapid Method of, C. E. R. Bruce and W. B. Whitney, 892
Sand-flies and Chinese Kala-azar, E. Hindle and Major W. S. Patton, 460; Major H. E. Short, 893
Science and Food Production, Sir E. J. Russell; The Reviewer, 636
Scientific Achievement and Aptitude, Prof. T. D. A. Cockerell, 84; Discovery, An Amusing Conception of, X.Y., 14
Sea Anemones, Fluorescence of, Major C. E. S. Phillips, 747
Sea Water, Measurement of Evaporation of, Prof. Was. Shoulejkin, 891
Secretion, The Problem of, Prof. J. P. Hill and Dr. J. A. Murray, 163
"Seizure" with Sliding Surfaces, J. M. Macaulay, 425
Sheep, The Coat of, Prof. J. Cossar Ewart, 426; Prof. J. E. Duerden, 815
Silicic Acid Gel during the Drying-up Process, Behaviour of, Dr. J. B. Firth and H. A. Fells, 84
Silver, The Atomic Weight of, Prof. B. Brauner, 348, 526; Prof. H. B. Baker and H. L. Riley, 348, 703
Simulium Larva, so-called 'Posterior Sucker' of a, The Mechanism of the, Dr. Sunder Lal Hora, 599
Solar Radiation: and Athermancy, A. F. Dufton, 14; and Diathermancy, A. F. Dufton, 460
Species, Fluctuations in the Abundance of a, considered Mathematically, Dr. A. J. Lotka; Prof. V. Volterra, 12
Spectrohelioscope, The, and Direct Telescopic View of Solar Prominences, A. A. Buss, 780
Spencer's, Herbert, Electrical Apparatus, F. W. Shurlock, 672
Spinning Electron, The, in Wave Mechanics, Prof. A. Carrelli, 492; E. Guth, 744
Stimuli in Plants, Transmission of, Prof. N. G. Ball, 638
Sulphur, Lengthened Chain Compounds of, Sir P. C. Ray, 124
'Sun Circles' in Ritual Dances, W. E. F. Macmillan, 14
Surfaces, The Polishing of, F. W. Preston; J. M. Macaulay, 13; N. K. Adam, 162, 279; Prof. J. Muir, 279; Dr. J. W. French, 527
Symmetrical Top, The, in Wave Mechanics, Prof. P. Debye and C. Manneback, 83
Tahitian Coral Reefs, Recession of the, Dr. C. Crossland, 597
Teleostean Fishes, Adrenal and Suprarenal Bodies in, The Homologues of the, Prof. Swale Vincent and F. R. Curtis, 83
Television, J. L. Baird, 161; Dr. A. Russell, 198
Teredo, Siphons of, Formation of Calcareous Tubes round the, Dr. C. M. Yonge, 11
Terrestrial Magnetism, Wireless Communication and, Dr. C. Chree, 82; Dr. W. H. Eccles, 157
Thyroxine, Designation of, Prof. A. T. Cameron, 925
Transmutation of Elements, Prof. L. Thomassen, 813
Truth or Convenience, Sir Oliver Lodge, 423
Tuning-Forks with Parallel Prongs, R. S. Maxwell, 124; Dr. G. E. Allan, 281
University Teachers, Salaries of, Prof. J. Read, 528
Upper Air, Thermodynamic Diagrams in the Study of the, Sir Napier Shaw, 118
Vacuum Flask, Early Suggestion as to the, R. Inwards, 893
Vapours, A New Pressure-Temperature Formula for, Prof. A. Batschinski, 198
Vertebrate Gut, Nomenclature of the, G. L. Purser, 855
Walrus, The, Dr. R. W. Gray, 923
Wave Mechanics: and the Radiation of Homopolar Molecules, D. M. Dennison, 316; The Symmetrical Top in, Prof. P. Debye and C. Manneback, 83
Whales, The Sleep of, Dr. R. W. Gray, 636
Wheat in 3500 B.C., Prof. J. Percival, 280
Winter Thunderstorms in the British Islands, S. M. Bower, 123
Wireless: Communication and Terrestrial Magnetism, Dr. C. Chree, 82; Dr. W. H. Eccles, 157; Waves, Propagation of, Effect of a Large Number of Receiving Aerials on the, R. H. Barfield, 195
Work done by Athletes, Rate of, Prof. A. S. Eve and A. J. Fleming, 86
X-ray: Diffraction in Liquids, Prof. C. V. Raman and C. M. Sogani, 601: Spectra, Soft, T. H. Osgood, 817; Spectrometer, An Unclaimed, P. E. Klopsteg, 14
Yolk Formation in some Arthropods, Mian Tasdique Husain, 817
'Zoo,' The Modern, T. H. Gillespie, 747
Zoological Nomenclature, Consideration of Six Cases in, Dr. C. W. Stiles, 817

Corrosion of Metal Joints, Dr. U. R. Evans, 941
Corrosive Action, The Influence of Boundary Films on, L. H. Callendar, 877
Cosmos: Conceptions of the: in Ancient Babylonia, Dr. R. Campbell Thompson, 170; in the Classical Period, Sir Thomas Heath, 247; according to Dante, Prof. E. Gardner, 280; from the Times of Copernicus to Galileo, Sir F. W. Dyson, 328; in the Galilean and Newtonian Period, Prof. H. H. Turner, 400; Present Conceptions of the, Prof. E. T. Whittaker, 502
Cotton: A Mutant in, G. L. Kottur, 747; Effect of Sunlight on, G. Barr and Isabel Hadfield, 255; Field Trials with, M. A. Bailey and T. Trought, 214; Occurrence of Branched Hairs in, and upon *Gossypium Stocksii*, W. Youngman and S. S. Pande, 745; Plant, The, M. A. Bailey and T. Trought, 869; Species, New, O. F. Cook and J. W. Hubbard, 796
Countryman, The, No. 1, 866
Coup-de-Poing, Prof. W. J. Sollas; H. Balfour, 490
Coupled Circuits, A Vector Loci Method of treating, E. Mallett, 412
Creeping Eruption in America, W. E. Dove and C. F. White, 367
Crehore (Dr. A. C.), The Progress of Atomic Theory, 410
Cretaceous Mammals, Teeth of, Prof. W. K. Gregory, 762
Crime and Custom in Savage Society, Dr. B. Malinowski, 633
Crimea: Palæontological Research in, 615; Wild Nature in, Preservation of, 580
Crimean Flora, Origin of the, Wulf and Prof. L. Berg, 904
Cromar, Deeside, Aberdeenshire, The Igneous and Metamorphic History of, H. H. Read, 621
Crustacea: Staining and Cleaning, Method of, R. J. Daniel, 766; The Segmental Excretory Organs of, Dr. H. G. Cannon and Miss S. M. Manton, 361
Crystal: Lattices, U. Panichi, 623; Structure in Biology, Sir William Bragg, 66; X-ray Photographs, Rotating, G. Greenwood, 586
Crystalline: Nitrates and Carbonates, The Magnetic Anisotropy of, K. S. Krishnan and Prof. C. V. Raman, 801; Sodium Nitrate, On the Form and Energy of, J. Topping and S. Chapman, 180
Crystallisation of Silver Beads and Detection of Platinum Metals by the Microscope, C. O. Bannister, 766
Crystals: Actual, Molecular Structure of, The Optical Proof of Lacunæ in the, A. Smekal, 222; Growth of, Sir Henry A. Miers, 758; Magnetism and Temperature in, Prof. W. Peddie, 621; Rate of Growth of, in Different Directions, M. Bentivoglio, 337; Twin Metallic, The Formation of, L. W. McKeehan, 392
Culture: Diffusion or Invention in, Dr. B. Malinowski, 65; The Diffusion of, Dr. R. R. Marett (Frazer Lecture), 410
Cuprammonium Ion and its Stability, The, P. Job, 373
Curie's and Hauy's Laws, A Demonstration of the Interdependence between, A. Bartorelli, 623

Current in Systems of Linear Conductors, A Principle Governing the Distribution of, F. Wenner, 221
Cycloheptene, Oxide of, The Action of Organo-magnesium Compounds on the, M. Godchot and P. Bedos, 373
Cyclones: and the General Circulation, Dr. H. Jeffreys, 637; The Mechanism of, T. Kobayasi, 832
Cygni, 61, The Orbit of, P. Baize, 403

Dactylis glomerata (Cocksfoot), The Chromosome Number in, J. G. Davies, 236
Dahomey, The Pictorial Records of, E. M. G. Waterlot, 760
Dairy Research Institute in Scotland, a committee for the management of the proposed, 402
Dairying, National Institute for Research in, 135, 649
Danish Ingolf-Expedition, Medusæ of the, Dr. P. L. Kramp, 367
Darius I., The Inscription of, Prof. E. Herzfeld, 792
Darwinism Dead? Is: Sir Arthur Keith, 75, 277, 526; H. Belloc, 277, 427, 526; Editor of NATURE, 427
Datura, A New Mutant in, Drs. C. S. Gager and A. F. Blakeslee, 940; Chromosome and Gene Mutations in, following Exposure to Radium Rays, C. S. Gager and A. F. Blakeslee, 731
Day, Length of the, Changes in the, Prof. E. W. Brown, 200; Dr. J. K. Fotheringham, 318
Dead, Disposal of the, at Wakching, Assam, J. H. Hutton, 683
Dead Sea, Water of the, R. Koefoed and G. Haugaard, 615
Death in a Superoxygenated Atmosphere, C. Achard, L. Binet, and A. Leblanc; C. Richet, 658

DEATHS.

André (Prof. G.), 933
Barnard (J.), 754
Bayard (F. Campbell), 326
Berthelot (Prof. D.), 432, 645
Brightmore (Dr. A. W.), 678
Brownlee (Dr. J.), 573
Bruckner (Prof. E.), 862
Bury (Prof. J. B.), 897
Carhart (Dr. D.), 132
Casale (Dr. L.), 609
Cathcart (G. L.), 609
Chauvenet (W. M.), 168
Collingridge (Dr. W.), 678, 789
Colvin (Sir Sidney), 754
Cook (Surg.-Genl. H.), 933
Crandall (Dr. I. B.), 933
Crossley (Dr. A. W.), 397, 498
Cvijić (Tzvyitch) (Prof. Y.), 432
Da Fano (Dr. C.), 534
Dall (Dr. W. H.), 678
Deacon (A. B.), 609
Delafosse (M.), 206
Des Coudres (Prof.), 645
Drechsel (Kommandeur C. F.), 432
Dumble (E. T.), 678
Edwardes (S. M.), 93
Eigenmann (Prof. C. H.), 862
FitzGerald (Prof. M. F.), 754, 823
Fox (Sir Francis), 93
Gilchrist (Prof. D. A.), 609, 789
Goodwin (H. B.), 361
Graebe (Prof. C.), 500
Greenhill (Sir George), 286, 323
Guthrie (F. B.), 361
Hamilton-Grierson (Sir Philip James), 678
Harding (C.), 132
Hartland (Dr. E. S.), 933
Haslam (Sir Alfred Seale), 245
Hell (Dr. K.), 168
Holborn (Dr. C. B. L.), 678
Howe (Dr. H. A.), 168
Hultzsch (Dr. E.), 286
Irving (B.), 168
Keltie (Sir John Scott), 130
Knowlton (Dr. F. H.), 326
Lawson (Prof. A. A.), 753
Lee (A. B.), 432
Levin (Dr. A.), 678
Lister (J. J.), 245, 360
Lochhead (Prof. W.), 862
Manouvrier (Dr. L. P.), 245
Marshall (Dr. C. E.), 678
Marshall (Col. C. H. T.), 397
Mellish (Lt.-Col. H.), 326
Miethe (Prof. A.), 754
Moore (Dr. F. J.), 132
Murray (Major J. R. Erskine), 361
Nicholson (Prof. J. S.), 754
Nutting (Prof. C. C.), 678
Owen (Sir Isambard), 132
Pargiter (F. E.), 397
Pearcey (F. G.), 245
Phillips (Prof. R. W.), 92
Pigott (Sir Digby), 206
Power (Dr. F. B.), 573
Pullar (Dr. L.), 59
de Quervain (Prof. A.), 205
Radlkofer (Prof. L.), 432
Remsen (Prof. Ira), 397, 608
Rennie (Prof. E. H.), 206, 361, 431
Richardson (Dr. S. W.), 645
Rigge (Father W. F.), 933
Ross (Dr. H. Campbell), 59
Rothmund (Prof. V.), 862
Rovsing (Prof. T.), 245
Runge (Prof. C.), 432, 533
Sargent (Prof. C. S.), 609, 645
Sars (Prof. G. O.), 609, 822
Scott (Prof. A. W.), 432
Seton (Dr. W.), 206
Shrubsole (W. H.), 862
Smith (Miss Matilda), 326
Spiegel (Dr. L.), 361
Starling (Prof. E. H.), 678, 715

Tzvyitch (Cvijić) (Prof. Y.), 432
Verrill (Dr. A. E.), 432
Walcott (Dr. C. D.), 286, 325
Walston (Sir Charles), 534
Warren (Genl. Sir Charles), 168
Wassmuth (Dr. A.), 933
Webster (J.), 168
Williams (Prof. W. C.), 862
Wilson (Sir James), 59
Withycombe (Dr. C. L.), 131

Decapod Crustacea, Fossil, Miss M. J. Rathbun, 905
Delphos: the Future of International Language, E. Sylvia Pankhurst, 889
Deltopecten, A New, from the Illawarra District, N.S.W., J. Mitchell, 947
Delusion and Belief, Prof. C. M. Campbell, 487
Denbighshire Technical Institute, Dr. W. Thomas appointed principal of the, 729
Desensitiser for Photographic Plates, A New, R. J. Garnotel, 100
Destruction of Organic Matter with the Aid of Perchloric Acid, The, E. Cherbuliez, 514
Destructive Insects and Pests Bill, The, 535
Development Commissioners, Sixteenth Report of the, 94
Devonian Flora, Dr. D. H. Scott, 368
Dewey, Melvil, The Decimal Classification of, and its Extension by the Brussels Institute of Bibliography, Dr. S. C. Bradford, 429
Dicotyledonous Fossil Wood from Ulladulla, N.S.W., A, C. Barnard, 948
Dielectric Bodies: Rotation of, in Electrostatic Fields, Dr. S. W. Richardson, 238; C. Record, 319; A. W. Simon and J. M. Cage, 816
Diet: and Cancer, with special reference to the Incidence of Cancer upon Members of certain Religious Orders, Dr. S. M. Copeman and Dr. N. Greenwood, 297; in Relation to Health, The Importance of, 44

Diffusion: or Invention in Culture, Dr. B. Malinowski, 65; Over Distances ranging from 3 km. to 86 km., Dr. L. F. Richardson and D. Proctor, 478; Pumps, The Theory of, L. Wertenstein, 34
Dilatancy, The Property of, L. B. Tuckerman, 602
Dinosaurs of Tendaguru, The, F. W. H. Migeod, 320
Diœcious Plants, Chromosomes of, C. A. Jorgensen, 726
Diphtheria, The Death-rate from, in Massachusetts for 51 years, 1875–1925, C. R. Doering, 659
Diphtheric Toxins giving rise to a Diphtherimorph bacillus, P. Hauduroy, 478
Disease: in the Tropics, Fighting, 828; Resistance in Plants, on the Nature of, W. A. Roach, 33
Dispersion, The Quantum Theory of, P. A. M. Dirac, 802
Disulphisatide, A. Wahl and Féricéan, 690
Divining Rod: Behind the, Dr. H. R. Mill, 310, 458; Dr. M. Culpin, 783; Prof. W. J. Sollas, 458, 565; The, an Experimental and Psychological Investigation, Sir William Barrett and T. Besterman, 310
Dogs Protection Bill, The Medical Research Council and the, 898
Dominions Overseas, British Settlement in the, 693
Dopes and Detonations, Prof. H. L. Callendar and others, 542
Doppler Effects and Intensities of Lines in the Molecular Spectrum of Hydrogen Positive Rays, M. C. Johnson, 412
Doublets, a Plane Network of, on the Mutual Potential Energy of, J. Topping, 180
Drawings on the Walls of the Reindeer Age in the Valley of Gardon, A Cave with, J. Bayol, P. Marcelin, and L. Mayet, 910.
Drumlins, The Glacial Origins of, Prof. J. K. Charlesworth, 727
Dug-out Canoe in Algoa Bay, Dr. R. N. Rudmose Brown; G. S. Laird Clowes, 856
Duplex Reversal Key, A, with Mercury Contacts, E. A. Griffiths and Dr. Ezer Griffiths, 909
Durgāpūja, A European Parallel to the, Dr. S. Konow, 99
Durian and the Rhio-Lingga Archipelago, The Fauna of, Dr. K. W. Dammerman, 371
Dust Clouds, Electricity of, G. B. Deodhar, 586
Dyeing, The Chemistry of, Dr. J. K. Wood. New edition, 742
Dyers' research medal, award of the, to Dr. H. H. Hodgson, 331
Dyes, Adsorption of, to Silver Halides: a Correction, Dr. S. E. Sheppard, 281
Dyestuffs and Coal-Tar Products: their Chemistry, Manufacture, and Application, T. Beacall, Dr. F. Challenger, Dr. G. Martin, and Dr. H. J. S. Sand. Fourth edition. Mar. 19 Suppt., 17
Dynamics: and Ballistics, 485; Apparatus for Demonstrating Experiments in, G. C. Sherrin, 25

Early Ancestors: Our, an Introductory Study of Mesolithic, Neolithic, and Copper Age Cultures in Europe and Adjacent Regions, M. C. Burkitt, 889
Earth: Constitution of the, Prof. H. H. Turner; Dr. H. Jeffreys, 295; Our Changing, E. B. Bailey, 421; Our Mobile, Prof. R. A. Daly, 421; Size and Figure of the, A. R. Hinks, 541; The Heat of the, Radioactivity and, Dr. R. W. Lawson, 277, 703; Dr. J. W. Evans, 424; The Peopling of the, Dr. A. Hrdlička, 253; The Relative Velocity of the, and the Neighbouring Ether, E. Brylinski, 373; Tremor in Scotland, 171
Earthquake: Chinese, of May 22, 936; in Japan, 401; in Scotland, An, 208; Research Institute, Japan, Inauguration of, 576; Prediction in California, Dr. J. P. Buwalda, 684
Earthquakes: along the Dalmatian Coast, 329; and the Tilting of the Ground, M. Ishimoto, 869; in California and Mexico, 60; in China, 826; in Latitude, The Distribution of, C. Maurain, 587
Earth's: Atmosphere, the, The Sun, and Radio Transmission, Prof. S. Chapman, 428; Crust, The Constituents of the, and the Molecular Number, P. Vinassa, 767; Surface Structure, The Origin of the, Prof. J. Joly and Dr. J. H. J. Poole, 524, 674
Earwigs, Variation in, Prof. J. S. Huxley, 507
Easington, Old Tithe Barn at, The, 364
East: Anglican Institute of Agriculture, Calendar of the, 32; Africa, The Early Peoples of, L. S. Leakey, 724
Easter, A Fixed, J. J. Withers, 331
Ebullioscopic Paradox, The, E. Briner and A. Schidlof, 587
Echinoderms: The Experimental Embryology of the (i.), P. Pasquini, 803; The Fertilisation Membrane in the, A. D. Hobson, 513
Eclipse: Observations, Meteorological Conditions in Relation to, R. Corless, June 18, Suppt., 70; Observing Parties and Stations, June 18, Suppt., 99; of the Sun: Naked-eye Observations of an, Annie S. D. Maunder, June 18, Suppt., 81; Partial, Spectroscopic Observations during a, Prof. A. Fowler, June 18, Suppt., 91; Radio Telegraphy and the, June 18, Suppt., 85; Phenomena, Prof. E. V. Appleton, 898; Photography, C. P. Butler, June 18, Suppt., 82; Problems: Astrophysical, Prof. H. Dingle, June 18, Suppt., 88; Modern, F. J. M. Stratton, 898; The Coming Total Solar, A. J. Hawkes, 794; The Forthcoming, Excursions and other Railway Arrangements, June 18, Suppt., 897; Time Signals for the, 903; Work, Astronomical Programmes of, F. J. M. Stratton, June 18, Suppt., 98
Eclipses: Prof. H. H. Turner, 102; Solar: Future Total, in the British Isles, Dr. A. C. D. Crommelin, June 18, Suppt., 77; The Recurrence of, Dr. J. Jackson, June 18, Suppt., 75; The Prediction of, Dr. L. J. Comrie, June 18, Suppt., 73
Economic Entomology, The Principles of Biological Control in, Dr. R. J. Tillyard, 202
Ecuador: Bird-Life in, The Distribution of, Dr. F. M. Chapman, 336; Birds of, 336
Edinburgh University: conferment of degrees, 32; gift by the International Education Board of New York towards the new department of zoology, 179; funds for a new department of zoology, 219; award of the Cameron prize to Prof. F. G. Banting, 258; Dr. R. J. Clark appointed lecturer, etc., in the department of natural philosophy; gift by T. Cowan, 372; Animal Breeding Research Department, 510; V. Gordon Childe appointed to the Abercromby chair of archæology, 511; impending conferment of honorary doctorates, 875; gift by T. Cowan, 907; grant by the Highland and Agricultural Society to the Department of Research in Animal Breeding; annual contribution to the British Institute in Paris, 943
Edison medal of the American Institute of Electrical Engineers, the, awarded to Dr. W. D. Coolidge, 251
Education: among Primitive Peoples; Origins of, a Comparative Study in Racial Development, W. D. Hambly, Mar. 19, Suppt., 10; and Industry, Departmental Committee on Interim Report of the, 69; of the Adolescent, Report of the Consultative Committee on the, 185
Educational Ladder, The, 810
Effectivity? Efficiency or, Prof. E. P. Cathcart, 599
Efficiency: Industrial and Commercial, Factors in, 305; or Effectivity? Prof. E. P. Cathcart, 599
Egypt: Early, The Court Life and Organisation of, 575; School of Archæology in, Report on the work of the, Sir Flinders Petrie, 433
Egyptian: Cotton, Branched Lint Hairs in, The Occurrence of, N. W. Barritt, 392; Ministry of Agriculture, Dr. W. L. Balls appointed director of the botanical section of the, 402; Tombs, Early, The Microscopical Study of Deteriorated Fabric from, A. C. Thaysen and H. J. Bunker, 802
Elective Fermentation, The So-called, A. Fernbach, M. Schoen, and M. Mori, 547
Electric: Cell, A Useful, Prof. S. L. Jindal, 639; Circuit Theory and the Operational Calculus, J. R. Carson, Mar. 19, Suppt., 18; Lamps, Methods of Testing, 140; Locomotives for Haulage Work in Factories, 936; Tetanus in Fishes, The Conditions of Death in, Dr. C. Richet, 910; Traction, F. Lydall, 176; Trains, R. E. Dickinson, Mar. 19, Suppt., 19; Tramways, The Equipment of, 169; Wave Phenomena, Large Scale, A Quantum Relation in, T. L. Eckersley, 234

Electrical: Communications, Fifty Years' Progress in, Prof. M. Pupin, 249; Conductivity of the Atmosphere: The, Dr. Rose Stoppel, 140, in the Region of the North Pole, Measurements of the, Malmgren and Běhounek, 947; Contracting: a Guide and Handbook specially designed to meet the Needs of all those engaged in Business as Electrical Contractors, H. A. Purdie, 632; Engineering: British Standard Glossary of Terms used in, 230; The Terminology of, 230; Illumination, Indoor, J. W. T. Walsh, 542; Instrument Design and Construction, Progress in, Dr. C. V. Drysdale, 101; Polarisation in Selenium Cells and the Effects of Desiccation, Prof. A. O. Rankine and J. W. Avery, 338
Electricity: in Conductors, Thermal Agitation of, J. B. Johnson, 50; in Warships, The Application of, W. McClelland, 575; Supply, J. A. Beard, 542; (Supply) Act, The, 755, The Theory of, Prof. G. H. Livens. Second edition, 385; through Gases, Conduction of, Prof. Seeliger, 653
Electrification and the Electricity Act, Sir Charles Bright, 207
Electro-conductivity Titration, A New Method of, E. Butterworth, 621
Electrodeless Discharge, The, and Active Nitrogen, G. Hornès, 910
Electrodynamics for Engineers, Introductory, Prof. E. Bennett and Dr. H. M. Crothers, 595
Electrolyte, Completely Dissociated, Interionic Forces in a, H. Hartley, 322
Electrolytes: Activity Coefficients of, V. K. La Mer, C. V. King, and C. F. Mason, 581; Strong, The Theory of, 676
Electrolytic Interruptor, The Mechanism of the, G. Colange, 182
Electromagnetic: Field, A Dynamical Theory of the, Prof. J. Clerk Maxwell, 125; Waves round the Earth's Surface, Refraction of, J. S. McPetrie and R. M. Wilmotte, 317
Electro-Mechanical Oscillators, C. B. Moore, 610
Electrometric Methods, Dr. E. K. Rideal, 346
Electron: Atoms and Ions, Physical Properties of many, The Theoretical Prediction of the, L. Pauling, 260; Emission under the Influence of Chemical Action at High Gas Pressures and some Photoelectric Experiments with Liquid Alloys, Prof. O. W. Richardson and M. Brotherton, 802; Orbits, Undulatory Theory of Two, Prof. A. W. Conway, 878; 'Reflection' *in vacuo*, D. Brown and Prof. R. Whiddington, 427; The, as a Vector Wave, Prof. C. G. Darwin, 282
Electrons: On the Capture of, by swiftly moving Electrified Particles, L. H. Thomas, 301; Spinning: R. H. Fowler, 90; and Protons, Prof. H. S. Allen, 237; The Effect of the Orbital Velocity of the, in Heavy Atoms on their Stopping of α-particles, L. H. Thomas, 445; The Scattering of, by a Single Crystal of Nickel, C. Davisson and L. H. Germer, 558; through Gases, The Passage of, H. Jones and Prof. R. Whiddington, 338
Electroscopes, A Convenient Method of Charging, Dr. H. H. Poole, 658
Elektrische Leitfahigkeit der Atmosphäre und ihre Ursachen, Die, Prof. V. F. Hess, Mar. 5, Suppt., 6
Elektrodynamik, Lehrbuch der, Prof. J. Frenkel. Erster Band, 851
Element: 61, Isolation of, Rolla and Fernandes, 27, 215; of Atomic Number 61, The Concentration and Identification of the, J. M. Cork, C. James, and H. C. Fogg, 339
Elements: The Thermal Ionisation of, Saha, Sur, and Mazumdar, 334; Transmutation of, L. Thomassen, 8[illegible]
Elephant-like Creatures represented in the New World, The Identification of, Prof. G. Elliot Smith, 132
Elephas antiquus of Pignataro, The, G. De Lorenzo, 333
Embryological Studies and Tissue Culture, 831
Embryology, Experimental: Dr. F. H. A. Marshall, 114; An Introduction to, G. R. de Beer, 114
Emeryville Shell Mound, The, California, W. R. Schenck, 438
Empire: Broadcasting, The Feasibility of, 757; Cotton Growing Corporation, Report of the, 291; *Cotton Growing Review, The*, Vol. 4, No. 1, 250; Foundations of, 841; Marketing Board, The Work of the, Mr. Ormsby-Gore, 680; Mining and Metallurgical Congress, Impending meeting in Canada, 575
Empty Quarter, The, Dr. P. A. Buxton, 381
Endocrine Organs: The, an Introduction to the Study of Internal Secretion, Sir E. Sharpey-Schafer. Second edition, Part 2, 420
Energy of Naturally Occurring Warm Water, The Utilisation of the, P. Villard, 106
Engineer: -Astronomer, An, 627; be trained? How should an, 225
England: Exploring, an Introduction to Naturecraft, C. S. Bayne, 668
English: Life in the Middle Ages, L. F. Salzman, 275; Opticians in the First Half of the Nineteenth Century, History of, Dr. M. von Rohr, 837
Entomological Society of Belgium, Dr. R. J. Tillyard elected an honorary member of the, 681
Entomology, Economic, The Principles of Biological Control in, Dr. R. J. Tillyard, 242
Enzyme: Die, Wirkungen und Eigenschaften, E. Waldschmidt-Leitz, 596; Research, Problems and Methods of, Prof. R. Willstatter, 790
Ephemera Danica, Mull., Biology of, E. Percival and H. Whitehead, 35
Erblichkeitslehre: Elemente der exakten, mit Grundzugen der biologischen Variationsstatistik, Prof. W. Johannsen. Dritte Auflage, 523
Eriostemon Coxii Mueller and *Phebolum dentalum* Smith, The Essential Oils of, A. R. Penfold, 303
Esfinge Indiana: La, antiguos y nuevos aspectos del problema de los origenes americanos, Prof. J. Imbelloni, 3
Eskimo in East Greenland, J. M. Wordie, 506
Eskimos and Plants, A. V. Kidder, 731
Essential Oils, The, H. Finnemore, 920
Estate Accounts, C. S. Orwin and H. W. Kersey, Mar. 19, Suppt., 12
Estheriæ of Australia, The Fossil. Part I., J. Mitchell, 947
l'Éther, Les équations de la dynamique de, Prof. H. Eyraud, 347
Ethylenediamine, The Substitution of, for Ammonia in Complexes in Solution, P. Job, 879
Etna, Laval Percolations from, Temperature of, G. Ponte, 691
Eucalypts, The Essential Oils of the, Prof. J. Read, 784
Euclid's Elements, The Thirteen Books of, Translated from the Text of Heiberg, with Introduction and Commentary, by Sir Thomas L. Heath. Second edition, 3 vols., 152
Euphausiacea and Mysidacea from the Western Atlantic, Prof. W. M. Tattersall, 614
Europa, Geologie von, Prof. Serge von Bubnoff. Band I., 232
Europium, The Arc Spectrum of, S. Piña de Rubies, 302
Evaporation, Latent Heats of, M. de Hemptinne, 373
Evolution: and Intellectual Freedom, Rev. Dr. H. Watson Smith, 288; The Teaching of the Truth of, in the U.S.A., The Supreme Court of Tennessee and, 134
Evolutionary: Advance: Emergent and Resultant, Prof. C. Lloyd Morgan, 786; Philosophy, Prof. J. Graham Kerr, 307
Ewing Ball-and-tube Flowmeter, Further Experiments with the, J. H. Awbery and Dr. Ezer Griffiths, 105
Excitation: by High Velocity Electrons, E. G. Dymond, 945; in Plants, Transmission of, Sir J. C. Bose, 48
Existence, The Continuity of, D. B. Marr, 199
Experimental Biology, Society for: meeting of the, 136; Easter conference of the, 681
Experimentalphysik, Handbuch der, Herausgegeben von W. Wien und F. Harms. Band 2: Mechanik der Massenpunkte und der Starren Korper, Prof. A. Haas, 189
Experimental Researches, Some, M. Hamy, 182
Exploded Wires, Prof. H. N. Russell, 829
Eye: Microscopy of the Living, B. Graves, 585; -strain in the Hosiery Industry, H. C. Weston and S. Adams, 726

Fairyland, A Road to, E. Fay, 313
Faraday House: Electrical Engineering College, appointment of the Rev. L. Van Vestraut as Registrar and F. A. Bell as Secretary, 619; Journal, Lent Term, 336; Medal of the Institution of Electrical Engineers, Award of the, to Prof. Elihu Thomson, 171; Michael, Proposed Memorial Library, 329
Farm: Calculations and Accounts, including a Thorough Treatment of Agricultural Calculations and of the Business Transactions of the Farm, Dr. A. G. Ruston and C. V. Dawe, Mar. 19, Suppt., 12; Measurements: A Practical Treatment of Problems in Mensuration, Dr. A. G. Ruston and C. V. Dawe, Mar. 19, Suppt., 12
Fasting of Large Ruminants, The, Dr. F. G. Benedict and E. G. Ritzman, 839
Fat-soluble Vitamins, 787
Fatty Acids: Higher, The Polymorphism of, Dr. J. Thibaud, 852; Polymorphism of, X-ray Investigation of the, G. M. de Boer, 634; X-ray Evidence for the Existence of Different Modifications of, G. M. de Boer, 50
Fatuoids in Cultivated Oats, The Origin of, C. L. Huskins, 49
Fayum Lakes, The, Sir Flinders Petrie, 238
Federow's Plate, Further Observations on the Apparent Duplication of the Optic Axis of Calcite by, N. Philibert, 107
Fermentations, Industrial, Prof. P. W. Allen, 741
Ferments, Preparation and Activity of, The Importance of Isoelectric Points in the, F. Chodat, 587
Ferns: Primitive, 191; The (Filicales): Treated comparatively with a View to their Natural Classification, Prof. F. O. Bower, Vol. 2, 191
Ferromagnetic Ferric Oxide, A New, R. Chevallier, 622; Substances, The Intrinsic Fields in, J. Dorfman, 353
Ferroso-ferric Cyanides, L. Cambi and Ada Clerici, 622
Ferrous Metals, The Action of Complex Saline Solutions on the, R. Girard, 690
Fields of Force in the Atmosphere of the Sun, The, Dr. G. E. Hale, 708
Filipinos, The Physique of, J. C. Nañagas and L. O. Santiago, 868
Fireball: Brilliant, on February 25, W. F. Denning, 366; of Feb. 25, The, W. F. Denning, 403; of March 1, W. F. Denning, 471; on June 10, W. F. Denning, 938
Fisheries: of Ceylon, The, Dr. J. Pearson, 68; River Pollution and, 1
Fishery Investigations at Cullercoats, 506
Fishes, New or Rare, C. F. Silvester and H. W. Fowler, 614
Fishing Industries of the Thames Estuary, the late Dr. Murie, 726
Fish Remains from the Upper Silurian Rocks of Ludlow, S. H. Straw, 766
Fisica dei corpuscoli, La, Dr. G. Gianfranceschi. Terza edizione, 419
Fjords, The Origin of, Prof. J. W. Gregory, 66
Flame: Movement, O. C. de C. Ellis, 870; Speeds, The Law of, Dr. W. Payman and Prof. R. V. Wheeler, 747, 779; The Supposed Law of, A. G. White, 51, 674; Dr. W. Payman and Prof. R. V. Wheeler, 238; Prof. W. A. Bone, 922; The Propagation of, H. F. Coward and G. W. Jones, 581
Flames, The Spectrography of, in an Explosion Motor, A. Henne and G. L. Clark, 262
Flat-fishes, Ambicoloration and Associated Variations in, J. R. Norman, 104; Natural Ambicoloration and the Production of Pigment in, J. T. Cunningham, 513
Fleas and Plague, Dr. L. F. Hirst, 540
Flinders Ranges, South Australia, The Geology of the, in the Neighbourhood of Wooltana Station, W. G. Woolnough, 303
Flint Surfaces: The Microscopical Examination of, J. Reid Moir, 560; W. J. Lewis Abbott, 747
Floræ Siamensis Enumeratio: a List of the Plants known from Siam, with Records of their Occurrence, Prof. W. G. Craib. Vol. 1., Parts 1 and 2, 633
Florentium: (Atomic number 61), A New Element, L. Rolla and L. Fernandes, 374; or Illinium? Prof. L. Rolla and L. Fernandes, 637
Florida, Miocene Mollusca from, Julia Gardiner, 139
Flour: Chemical Treatment of, 797; the Colour of, A Numerical Expression for, D. W. Kent-Jones and C. W. Herd, 690; The Relative Food Values of Brown and White Wheaten, E. J. Sheehy, 803
Flowering Plants, Multiple Chromosomes and Reduction Division in, Dr. J. Belling, 122
Flowmeter, A Ball and Tube, Suitable for Pressure Circuits, J. H. Awbery and Dr. Ezer Griffiths, 657
Fluid, Superposed Streams of, An Experiment on the Stability of, Prof. G. I. Taylor, 657
Fluorescence: Action of the Antioxygens on, Privault, 910; Decay of, E. Gaviola, 66
Fluorine, Arc Spectrum of, The Double Normal State of the, Prof. H. Dingle, 86
Food: Fishes in the North Sea, Distribution of, J. O. Borley, 540; Production, Science and, Sir E. J. Russell; The Reviewer, 636
Foot-and-Mouth Disease, Report on, 906
Foraminifera from the Suez Canal, E. Heron-Allen and A. Earland, 939
Forest: Administration in British Honduras, 257; Crops: Measurements of the Cubical Contents of, being a critical investigation into the methods of measuring Sample Plots, with special reference to the liability to error, M. D. Chaturvedi, 192; Destruction and its Effects, 37; Steppe and Tundra: Studies in Animal Environment, Maud D. Haviland (Mrs. H. H. Brindley), 385
Forestry: and Forest Products Research, Co-operation in, 881; in Illinois and Great Britain, 317; Research in South Africa, J. Phillips, 333
Formic Acid, The Catalytic Decomposition of, J. B. Senderens, 730
Forrest, James, Lecture, The, Prof. H. C. H. Carpenter, 927
Fossil: Bone Implements of Pliocene Age, Discovery in Nebraska of, Dr. H. F. Osborn, 790; Permian Insects from European Russia, Dr. A. V. Martynov, 440
Foulden, Berwickshire, The Fish-fauna of the Cementstones of, E. I. White, 182
Fowl: Domestic, Relation of Gonadic Structure to Plumage Characterisation in the (ii.), A. W. Greenwood and Dr. F. A. E. Crew, 877; Relation of Gonad and Plumage in the, Pézard, Sand, and Caridroit, 99; the Quantitative Relation of Comb Size and Gonadic Activity in the, A. W. Greenwood and Dr. F. A. E. Crew, 803
Fowls, The Erythrocyte Count in Sexually Normal and Abnormal, A. C. Chaudhuri, 145
France, Statistique intellectuelle de la, T. Beresovski-Chestov, 345
Free: Pendulum, A, maintained by a Photo-electric Current and its Application to the Problem of Time, G. Ferrié and R. Jouaust, 302; Place Scholarships Examination, 1926, in Kent, The, A. Bell, 219
Fresh-water: Life, Microscopic, F. J. W. Plaskitt, 117; Polyzoa in East Anglia, Ecology of the, H. E. Hurrell, 766
Fresnel's Convection Coefficient in General Relativity, On, N. R. Sen, 877
Friction Match, The Centenary of the, Prof. W. A. Bone, 495
Fruit: Growing, Prof. W. H. Chandler, Mar. 19, Suppt., 11; Tree Spraying, Modern, and What it Costs, J. Turnbull, 828
Fuel: Institute of, Fusion of the Institution of Fuel Technology and the Institution of Fuel Economy Engineers under the Name of the, 681; Research Board, Report of the, for 1926, 211; Technology, Institution of, Inaugural Meeting of the, 136
Fugle. 2: Lomfugle, Stormfugle, Vandhøns, Tranefugle og Vadefugle, R. Hørring, Mar. 5, Suppt., 2
Fulminating Material, The Study of, E. Mathias, 446
Fungal Diseases, Seed Mixtures and Incidence of, E. W. Fenton, 657
Furfural in Vinegar, On the Presence and Detection of, L. H. Lampitt, E. B. Hughes, and L. H. Trace, 34
Furnace Development, Prof. W. E. S. Turner, 909
Fused Salt, The Coefficient of Ionisation of a, Prof. T. M. Lowry, 564
Fütterung der Haustiere: ihre theoretischen Grundlagen und ihre wirtschaftliche Durchführung, Prof. N. Hansson. Übersetzt von F. von Meissner, 486

γ-Ray Absorption, Temperature Coefficient of, L. Bastings, 51
Gabb's Californian Fossil Gastropods, R. B. Stewart, 255
Gadolinium, The Arc Spectrum of, S. Piña de Rubies, 586
Galactic Cepheids, Statistical Properties of, J. Schilt, 212
Gallium in Flue Dust, H. Ramage, 783
Gambusia, Sexual Maturation of, Phenomena accompanying the Crisis of, E. Remotti, 414
Gamma Rays, The Scattering of, Dr. L. H. Clark, 121
Gammarus chevreuxi Sexton, Inheritance in, Mrs. E. W. Sexton and C. F. A. Pantin, 119
Gas: Ion Mobilities in Ether-hydrogen Mixtures, L. B. Loeb, 146; Storage of Fruit, F. Kidd, C. West, and M. N. Kidd, 830
Gaseous: Combustion at High Pressures (Part vii.), Prof. W. A. Bone and D. M. Newitt, 802; Explosions, The Initial Stages of, Prof. W. A. Bone, R. P. Fraser, and D. A. Winter. 2 Parts, 259, 763; Prof. W. A. Bone, R. P. Fraser, and F. Witt, 545; Mixture, The Equation of State of a, Dr. J. E. Lennard-Jones and W. R. Cook, 545; Mixtures: of Acetylene and of Pentane, On Detonation of, A. Egerton and S. F. Gates (1), 259; On Detonation of, at High Initial Pressures and Temperatures, A. Egerton and S. F. Gates (2), 259; The Pressure of, Dr. J. E. Lennard-Jones, 459; Reactions, The Mechanism of, 771
Gases: in Nitrous Oxide, The Burning of, Prof. H. B. Dixon and W. F. Higgins, 296; The Activation of, by Adsorption, G. B. Kistiakowsky, 650; The Ionisation of, and the Temperatures of the Stars, G. Tiercy, 514
Gaussmeter, A. A Direct Reading Apparatus for the Measurement of Magnetic Fields, G. Dupouy, 478
Geine (Geoside), The Chemical Composition of, H. Hérissey and J. Cheymol, 183
Geissler Discharge in Argon, The, Dr. K. G. Emeléus and N. L. Harris, 602
Genetics at the Carnegie Institution of Washington, Dr. Banta, 904
Genius: Genetic Studies of, edited by L. M. Terman. Vol. 1: Mental and Physical Traits of a Thousand Gifted Children, L. M. Terman and others. Second edition. Vol. 2: The Early Mental Traits of Three Hundred Geniuses, by Catherine Morris Cox and others, 695; The Numerical Measurement of, 695
Geodesy and Geophysics, International Union of, Publication of Vol. 3 of the Proceedings of the Geodesy Section, 936
Geodetic Constants and the Values of Gravity, Relations existing between the, C. Somigliana, 475
Geographical Association, The, Annual Meeting of, 142
Geography, the new title of the *Geographical Teacher*, 538
Geological Society: of London, Awards of the, 169, 329, 504; election of officers, 330
Geology: of South Africa, The, Dr. A. L. Du Toit; Prof. J. W. Gregory, 665; of the country between Llanelidan and Bryneglwys, B. C. Blackie, 878
Geometry, Theoretical, The Greek Conception of, Prof. G. A. Gibson, 152
Geophysics, Modern, Dr. H. Jeffreys, 343
Geophysik, Lehrbuch der, Herausgegeben von Dr. B. Gutenberg. Lief. 1 und 2, 343
Gianfranceschi (Dr. G.), La fisica dei corpuscoli. Terza edizione, 419
Gibbs' Phase Integral for Imperfect Gases, The Evaluation of, H. D. Ursell, 445
Gifford Lectures, The, Prof. A. S Eddington, 170, 208, 249, 289, 328, 363, 399, 434, 468
Gigha, The Geology of, W. J. M'Callion, 302
Gisortia, The Molluscan Genus, late Dr. Vredenburg, 684
Giza, An Archæological Discovery at, Dr. Reisner, 791
Glasgow: *Royal Technical College, Journal of the*, Dec., 867; University, Awards in, 656
Glass: Fragments in Preserved Foods, G. C. Hancock, 614; Furnaces, Recuperative, Some Further Developments in, T. Teisen, 621; Technology, Society of, W. Butterworth re-elected president, 827
Glasses and Glazes, Some Colouring Agents in, Sir Herbert Jackson, 401
Glencoin and Stybarrow, The Woods of, 756
Globular Clusters and Spiral Nebulæ, A. R. Hinks, 725
Glucose Solutions, Alcoholic Fermentation of, exposed to the Action of Ultra-violet Rays, R. de Fazi, 803
Gluten from Flour, The Washing of, D. W. Kent-Jones and C. W. Herd, 690
Gmelin's Handbuch der anorganischen Chemie. Achte Auflage. Herausgegeben von der Deutschen Chemischen Gesellschaft. Bearbeitet von R. J. Meyer. Number 13 und 5, 346
Gods, The Goodness of, Prof. E. Westermarck, 557
Gold: A New Organo-metallic Derivative of, A. Lumière and F. Perrin, 414; from Mercury, The Formation of, Miethe and Stammreich, 474
Gold Coast Survey, 406
Golden Eagle, Filming the, Capt. C. W. R. Knight, 536
Goldsmiths' Company, The, 501
Golgi: Apparatus, The, in the Cells of Tissue Culture, Dr. R. J. Ludford, 512; Bodies, The Nature of, and other Cytoplasmic Structures appearing in Fixed Material, C. E. Walker and Margaret Allen, 512
Gosforth District, N.S.W., Geology of the. Part 1, General Geology, W. R. Browne, 222
Graft of a Regenerated Member and Induced Differentiation, E. Guyénot and O. Schotté, 622
Grain Beetle, Saw-toothed, The Biology of the, E. A. Back and R. T. Cotton, 368
"Grammar of Science," Unauthorised Publication of the, Prof. Karl Pearson, 926
Grampian Mountains of Victoria, Australia, The Flora of the, E. Ashby, 104
Granite-schist Junction in the Leinster Chain, The Topographical Features of the, A. Farrington, 145
Graphite: Formation in White Cast Irons, The Influence of Carbon and Silicon on, P. Chevenard and A. Portevin, 182; Suspension for Intravital Injection of Capillaries, A, C. K. Drinker and E. D. Churchill, 878
Grass, Hybrid Vigour in, T. J. Jenkin, 683
Gravitation, Comets and the Law of, Dr. A. C. D. Crommelin, 464
Great Barrier Reef, Impending Marine Biological Research upon the, 468
Great Britain, Mycology in, 256
Greek People, The Formation of the, Prof. A. Jardé. Translated by M. R. Dobie, Mar. 19, Suppt., 9
Green Manuring, 830
Greenhouse White Fly, A Parasite of the, E. R. Speyer, 868
Greenland, Phytogeography of, C. H. Ostenfeld, 761
Greenwich, Royal Observatory, Annual Visitation, 873
Grevillea (Proteaceæ), A Case of Natural Hybridism in the Genus, C. T. Musson and the late J. J. Fletcher, 948
Grewia polygama, The Leaves of, Alice M. Coverlid, 838
Growth: Inhibiter, A Universal, in Living Tissue, P. O'Connor, 946; Light and, 543; The Physiology of, 269
Guest, The Divinity of the, A. M Hocart, 540
Gulf of Carpentaria, The Salinity of the Water of the, G. J. Burrows, 222
Gum Arabic: with Special Reference to its Production in the Sudan, H. S. Blunt, Mar. 19, Suppt., 11
Gunfire, Audibility of, F. J. W. Whipple, 782
Guthrie Lecture, The, Sir Ernest Rutherford, 363
Guy's Hospital Medical School, E. Matthews appointed demonstrator in the Chemistry Department of, 69
Gypsum, Dehydration of, The Thermal Analysis of the, R. Stumper, 837
Gypsy: Linguistics, Prof. R. L. Turner, 830; Marriage Customs in Eastern Rumelia, 174

Haas (Prof. A.), Die Welt der Atome: Zehn gemeinverstandliche Vortrage, 419
'Hackleless' Fowl, Pterylosis in the, A. W. Greenwood, 261
Hadrian, The Wall of, Sir George Macdonald, 434
Hæmocyanin, Oxidation of, Colorimetric Determination of the, Prof. L. Hogben, 122
Hæmolysis, Percentage, The Measurement of (ii.), E. Ponder, 220

Hafnium, Persistent Lines of, M. Petersen, 352
Hair Hygrometers, The Behaviour of, A. N. Puri, 145
Hairsprings, The Manufacture and Properties of, H. Moore and S. Beckinsale, 584
Hales, Rev. Stephen, 250th anniversary of the birth of, 936
Halides of Bivalent Metals, Additive Compounds of, with Organic Bases (iii.), G. Scagliarini and G. Tartarini, 107
Halley Lecture, The, F. J. M. Stratton, 898
Halobates, The Eggs and Young of, Dr. H. C. Delsman, 651
Halophytes, Chemistry of, J. Zellner, 36
Hardness: of Metals in relation to Periodicity, S. A. Korff, 818; Tests of, Stresses involved in, and a Table of the Comparative Hardness of Certain Metallic Elements, A. Mallock, 276
Hartmann Formula for the Dispersion of Glass, The, H. W. Lee, 657
Haute-Provence, The Astronomical Quality of the Sky of, A. Couder, A. Danjon, and A. Dufay, 221
Hawaiian Islands, The Insect Fauna of the lesser known, E. H. Bryan and others, 579
Hawkesbury River between Windsor and Wiseman's Ferry, The Physiography and Geography of the, Miss Lesley D. Hall, 262
Haystacks, Spontaneous Combustion of, G. Laupper, 541
Haze, Dr. J. S. Owens, 561
Health: Wealth and Population in the Early Days of the Industrial Revolution, M. C. Buer, 379; Week, The Celebration of, 902
Heat: Convection of: in Fluid Flow through Pipes, H. M. Martin, 672; in Fluid Flow through Tubes, H. F. P. Purday, 527; Theorem: The New, its Foundations in Theory and Experiment, Prof. W. Nernst, translated by Dr. G. Barr, 43; through a Brick Wall, Transmission of, L. R. Ingersoll and J. Bardeen, 892
Heath-association on Hindhead Common, Prof. F. E. Fritch, 620
Helion? Helium or, Dr. J. Newton Friend, 199
Helium: Arc Spectrum, The Fine Spectrum of the, W. V. Houston, 838; Electron Scattering in, Dr. E. G. Dymond, 581; or Helion? Dr. J. Newton Friend, 199; The Transmutation of Hydrogen into, Prof. F. Paneth, 706
Hemimysis Lamornae, On the Feeding Mechanism of, Prof. H. G. Cannon and Miss S. M. Manton, 105
Hemiptera, Classification of, Dr. W. E. Britton, 540
Herbarium Method, An Improved, for Geneticists, Ecologists, and Taxonomists, E. M. Marsden-Jones and W. B. Turrill, 620
Herculaneum, Impending Excavations of, 248
Heredity, Prof. A. F. Shull, 156
Herschel's Condition, On, and the Optical Cosine Law, G. C. Steward, 478
Heterogeneous Fluid Mass in Rotation, The Stratification of a, R. Wavre, 622
Hewlett Collection of Stone Implements, The, A. Keiller, 611
Hicksonia, The Genus, Isobel Deans, 546
High: Vacua, Dr. G. W. C. Kaye, Mar. 19, Suppt., 15; Voltage Overhead Transmission, 474
Higher Degrees, Report on, 143
Himalayan Silver Fir and Aeroplane Construction, The, 728
History, The New Outlook in, F. S. Marvin, 591
Hittite Studies, The Progress of, Prof. J. Garstang, 819, 860
Holism and Evolution, Gen. the Rt. Hon. J. C. Smuts, 307
Home Fires without Smoke: a Handbook on the Prevention of Domestic Smoke, edited by C. Elliott and Marion Fitzgerald, Dr. J. S. Owens, 812
Hommes fossiles, L'Art et la religion des, G.-H. Luquet, 8
Homogeneous Reactions involving Complex Molecules, C. N. Hinshelwood and G. J. Askey, 801
Hordeum vulgare, Protoplasm of Root-hairs in, Influence of Hydrogen Ion Concentration on the, S. Strugger, 222
Horns, The Growth of, Dr. J. U. Duerst, 472
Horticulture, The Principles and Practice of, A. S. Galt, Mar. 19, Suppt., 11
Huaxtec, The Indians of, Dr. W. Staub, 367
Human: Adventure, The, (1) The Conquest of Civilisation, Prof. J. H. Breasted. (2) The Ordeal of Civilisation: a Sketch of the Development and World-wide Diffusion of our Present-day Institutions and Ideas, Prof. J. H. Robinson, 591; Biliary Calculi containing a High Proportion of Copper, J. Meunier and Mlle. G. Saint-Laurens, 183; Life, Science and, 449; Race, The Pedigree of the, Prof. H. H. Wilder, Mar. 19, Suppt., 9; Races, Old and New, Sir Arthur Keith, 247
Humic Matter, The Origin of, C. E. Marshall and H. J. Page, 393
Hutton, James, Father of Modern Geology, 1726–1797, E. B. Bailey, 582
Huxley Memorial Lecture, Dr. P. Chalmers Mitchell, 721, 748
Huyghens' Principle and the Phenomena of Total Reflection, Prof. C. V. Raman, 657
Hyacinthus, Bivalents of, The Nodes at the Reduction Division in, Dr. J. Belling, 527
Hydrocarbons, The General Preparation of, by the Reduction of Organic Substances, J. Campardou, 690
Hydrofluoric Hydrolysis of the Proteids, The, E. Cherbuliez and R. Wahl, 262
Hydrogen: and Nitrogen, Compressibility of, E. P. Bartlett, 797; Atom, Oriented, The Effective Cross-section of the, R. G. J. Fraser, 260; Atoms, The Stopping Power of, for α-particles according to the New Mechanics, J. A. Gaunt, 657; Balmer Lines of, Fine Structure of the, P. A. Constantinides; Lord Rayleigh, 163; Band Spectrum: The, New Band Systems in the Violet, Prof. O. W. Richardson, 801; Chloride Vapour, Ionisation in, H. A. Barton, 197; Connexion between the Visible and Ultra-violet Bands of, Prof. O. W. Richardson, 801; Fluoride, Ionisation Potential of, Prof. S. C. Biswas, 707; into Helium, The Transmutation of, Prof. F. Paneth, 706; Iodide, Photochemical Decomposition of, B. Lewis, 493; Ion Concentration: Influence of the, on the Respiratory Exchanges of the Tissues, M. Comel, 767; its Significance in the Biological Sciences and Methods for its Determinations, Prof. L. Michaelis. Vol. 1: Principles of the Theory, translated by Dr. W. A. Perlzweig, 346; of the Blood in Health and Disease, Prof. J. H. Austin and Prof. G. E. Cullen, 742; Peroxide, Preparation of, M. L. Kilpatrick, 334; Secondary Spectrum of, Bands in the, Prof. H. S. Allen and I. Sandeman, 412; The Infra-Red Spectrum of, Dr. A. H. Poetker, 123; The Magnetic Moment of, T. E. Phipps and J. B. Taylor, 474; The Specific Heat of, Dr. F. Hund, 762; The Use of the Discharge in, as a Source of a Continuous Spectrum in the Ultra-violet, M. Lambrey and D. Chalonge, 879
Hydrographic Surveying, Commdr. J. H. Hawley, 831
Hydroxides, Modified, The Magnetic Behaviour of the, in the Presence of Hydrogen Peroxide, Mlle. Suzanne Veil, 947
Hygiene, Bulletin of, The, 578
Hyperorthogonants, Note on, Sir Thomas Muir, 838
Hythe Skulls, The, Prof. F. G. Parsons, 893

Icebergs: Destruction of, Prof. H. T. Barnes, 761; in Relation to Water-Temperature, W. Bell Dawson, 236
Iceland, The Palagonite Formation of, Dr. G. W. Tyrrell and Dr. M. A. Peacock, 507
Illinium: Prof. W. A. Noyes, 319; Florentium or, Prof. L. Rolla and L. Fernandes, 637
Illipé Butter in Chocolate, The Determination of, H. W. Bywaters, F. T. Maggs, and C. J. Pool, 546
Illuminating Engineering Society, D. R. Wilson nominated president of the, 612
Illumination Research Committee of the Department of Scientific and Industrial Research, Technical Papers 1, 2, 3, 63
Immersion Refractometer, The, and its Value in the Analysis of Milk, G. D. Elsdon and J. R. Stubbs, 413
Imperial: College and Tropical Agriculture, Report of the, Dr. H. Martin Leake, 688; Forestry Institute: Second annual report of the, 96; The, Prof. R. S. Troup; The Writer of the Note, 197; Institute: Annual Report of the, for 1926, 824; Conducted Tours for School Teachers in the Exhibition Galleries of the, 103; Panoramas at the, 23

India: The Survey of, 541; War Record, 1914–1920, 7
Indian: Lac Research Institute, The, 299; Lepidoptera with Abnormal Habits, Some, T. V. Ramakrishna Aiyer, 146; Science Congress, election of Dr. J. L. Simonsen as president of the, 252; Zoological Memoirs on Indian Animal Types. I.: Pheretima (The Common Indian Earth-worm), Prof. Karm Narayan Bahl, 557
Indium in Tin, The Occurrence of, J. R. Green, 893
Industrial: Accidents, The Practical Application of the Statistics of Repeated Events with special reference to the Personal Factor in, Miss E. M. Newbold, 730; and Commercial Efficiency: Factors in, being Part I. of a Survey of Industries, 517; Fatigue Research Board, Report of the, 172; Research: Co-operative, 646; The State and, 589; Revolution, The: 379; E. W. Hulme, 671, 892; Mabel C. Buer, 671; H. W. Dickinson, 818
Infusoria, Appearances of Struggle and of Parasitism with Simulations of, L. Herrera, 106
Insecticides, Contact, The Toxicity of, F. Tattersfield and C. T. Gimingham, 546
Insects: Metamorphosis of, O. W. Tiegs, 35; Phytophagic or Biological Races in, E. Meyrick, 782; W. H. Thorpe, 602; Prothetely in, Dr. Hem Singh Pruthi, 391
Insektenlarven, Die Ökologie der blattminierenden, Dr. M. Hering, 232
Institute of Chemistry, annual general meeting of the, election of Prof. A. Smithells as president for 1927–28, 402
Institution of Electrical Engineers, Speech by the Prince of Wales at the annual dinner of the, 287
Insulin, L. Schmid and G. Bilowitzki, 374
Intellectual Activities in France, 345
Interionic Forces in a Completely Dissociated Electrolyte, H. Hartley, 322
Internal Combustion Motors, The Use in, of Slightly Inflammable Combustibles, P. Dumanois, 182
International: Botanical Congress: Arrangements for the Fifth, 208; of 1930 to be held in Cambridge, 436; Congress of Orientalists, to be held in 1928, at Oxford, 723; Critical Tables of Numerical Data, Physics, Chemistry and Technology, Editor-in-Chief: Dr. E. W. Washburn. In 5 Vols. Vol. 1, 735; Federation of Intellectual Unions, Report of the third assembly of the, 209; Illumination Commission, The, 900
Interpolation, Prof. J. F. Steffensen, 921
Invention in Culture, Diffusion or, Dr. B. Malinowski, 65
Iodine: and Bromine, Thermal Dissociation of, Devries and Rodebush, 797; Vapour, The Fluorescence of, G. Ramsauer, 334
Iodo-Bismuthites, The Preparation of certain, Miss E. M. Bartholomew and G. J. Burrows, 222
Ionic Theory, The, Brig.-Gen. H. Hartley, 102
Ionisation: Formula, Some Applications of the, Cecilia H. Payne, 339; Simultaneous, and Excitation by Foreign Ions in a Gaseous Mixture, Prof. C. S. Duffendack and H. L. Smith, 743
Ions: and Atoms or Molecules, Collisions of the Second Kind between, Dr. H. D. Smyth, G. P. Harnwell, T. R. Hogness and E. G. Lunn, 85; d'hydrogène: Les, signification, mesure, applications, données numériques, W. Kopaczewski, 546; The Absorption of, by Glass, H. Devaux and E. Aubel, 587
Ipsilateral Spinal Reflexes, Interaction between, acting on the Flexor Muscles of the Hind-limb, Sybil Cooper, D. E. Denny-Brown, and Sir Charles S. Sherrington, 512
Irish: Moss Mucilage and a Method for its Determination, Dr. P. Haas and Barbara Russell-Wells, 413; Spiranthes, The, called *S. Romanzoffiana* Cham., A. J. Wilmott, 546
Iron: Archæology of, 42; Crystals, L. W. McKeehan, 705; in Antiquity, Dr. J. Newton Friend, 42; manganese Alloys low in Carbon, Thermal Changes in, Sir Robert Hadfield, 801; Nickel, and Cobalt, Non-Magnetic Films of: J. D. Hanawalt and Prof. L. R. Ingersoll, 234; Dr. L. C. Jackson, 426; Nitrosulphides, Constitution and Absorption Spectra of the, L. Cambi and L. Szegö, 374; Oxide Coatings, Structure of, R. M. Bozorth, 832; Single Crystals of, The Transverse Magneto-resistance Effect in, W. L. Webster, 545; Sulphide in Contact with Water, The Evolution of, Mlle. S. Veil, 182
Irrawaddy Delta Air Survey, Major C. G. Lewis, 173
Isohydric Solutions and the Velocity of Chemical Change, H. M. Dawson and C. R. Hoskins, 35
Isostasy in Spain, W. Bowie, 27

Jaintia Hills, Some Megalithic Work in the, J. H. Hutton, 374
Japan: Science in, Prof. C. C. Farr, 407; Tertiary Shells from, Prof. M. Yokoyama, 26
Japanese: Earthquake of: March 7, 1927, The, Dr. C. Davison, 443; Sept. 1, 1923, The: Prof. A. Imamura, 139; Land Movements during the, Major-Genl. H. Omura, 254; Minerals, Helium Content of, J. Sasaki, 541; Volcanoes, The Echelon Structure of, S. Fujiwhara, 473
Java, Freshwater Eels in, Dr. H. C. Delsman, 579
Jenissei: Bronzezeit am, ein Beitrag zur Urgeschichte Sibiriens, Gero v. Merhart, 775
Jerusalem, The Hebrew University of, 656
Juniper in Norway, F. R. S. Balfour, 214
Jupiter: Changes observed on the Planet, E. M. Antoniadi, 146; Danish Observations of the Planet, 29; La surface de la planète, 1919–1924, C. L. Janssen, 29

Kala-azar, Sand-flies and, Major H. E. Short, 893
Kammerer's Water-bred Alytes, The Nuptial Pad of: W. C. Kiplinger; Prof. H. Przibram, 635; Prof. E. W. MacBride, 707
Kant to Einstein, From, H. de Montmorency, Mar. 19, Suppt., 14
Karachi, Fauna of, S. S. Bindra, 905
Katanga, A Mineral from, H. Buttenbach, 910
Kateruk Series, The, and Associated Rocks of the Northern Suk Hills, Kenya Colony, V. G. Glenday and J. Parkinson, 689
Kent's Cavern, Torquay, Human Skull from, Sir Arthur Keith, 614
α-Ketonic Acids, A New Method of Preparing, Barré, 690
Kew, Royal Botanic Gardens, H. C. Sampson appointed economic botanist at the, 577
Khallam, The, Miss Erna Gunther, 683
Kilauea, A New Observatory opened at, 865
King's Birthday Honours, The, 863
King's Classical Theory of Radiation, B. Podolsky, 838
Kirondrine, The Bitter and Toxic Principle of Kirondro Seeds, Volmar and Samdahl, 478
α-Kirondrine, The Constitution of, Volmar and Samdahl, 547
'Knock' Suppression, The Mechanism of, Prof. H. S. Taylor, 746
Kolbe's Electrosynthesis, Mechanism of, D. A. Fairweather and O. J. Walker, 215
Kordylewski's Variable Star, 613
Krakatau, The Recolonisation of, by Animal Life, Dr. A. D. Imms, 370
Kriegsschauplatze 1914–1918 geologisch dargestellt, Die, Herausgegeben von Prof. J. Wilser. Heft 14, Mar. 5, Suppt., 8
Kultur: Frühschein der, Bilder aus Vorgeschichte und Urzeit, Prof. J. Ledroit, Mar. 5, Suppt., 2

Lac Research Institute, The Indian, 299
Lactose, Synthesis of, A. Pictet, 262
Lamb's Valley and the Paterson River, Geology of the Country between, Prof. G. D. Osborne, 947
Lamsiekte in Cattle in South Africa, Sir Arnold Theiler and others, 904
Land: Planarians, Some, from Barrington Tops, N.S.W., with Descriptions of New Species, Lucy M. Wood, 107; Politics and Economics, Christopher Turnor, 845
Langerhans, Islets of, Secretion and the Golgi Apparatus of, Dr. R. J. Ludford and Dr. W. Cramer, 144

Laplace: Centenary of the death of, 362; The Bram of, Prof. Karl Pearson, 560; The Tomb of, Eng.-Capt. E. C. Smith, 493
Large Ions, Measurements of the, at Paris, J. MacLaughlin, 947
Latent (or Developable) Image, Intensification of the, Wightman and Quirk, 619
Lathræa, The Pollen Development of Two Species of, Prof. R. R. Gates and J. Latter, 909
Laying Hen with Cock's Plumage, The (iii.), Dr. F. A. E. Crew, 877
Lead: Accumulators, Products formed during the Action of (ii.), L. Mazza, 623; Determination of Certain Elements in, New Processes for the, B. S. Evans, 837; Mining and Smelting in West Yorkshire, Dr. A. Raistrick, 537; -tin Eutectic, Crystallisation of the, F. Hargreaves, 585
Leaf Structures and Wound Response, Prof. R. B. Wylie, 405
League of Nations, The: as a Subject of Instruction in the Schools of Great Britain, 908; The International Labour Organisation of, 908
Lebistes, Genetics of, Dr. Winge, 831
Lecithines, A New Histochemical Reaction for the, M. Romieu, 947
Leeds University, gift for the mining department of, 511
Leguminosæ, 'Hard Seeds' in, C. J. Berkeley, 198
Leishmania: tropica, L. infantum, and *L. braziliense* in the Sandfly, *Phlebotomus papatasii*, The Behaviour of Cultures of, Dr. S. Adler and O. Theodor, 48, 565
Lepidoptera: Hereditary Choice of Food-plants in the, and its Evolutionary Significance: E. Meyrick, 388; Dr. J. W. Heslop Harrison, 562; The Induction of Melanism in the, and its Evolutionary Significance, Dr. J. W. Heslop Harrison, 127
Leprosy, A New Drug Treatment of, Dr. E. Muir, 362
Lewes, George Henry, Sir E. Sharpey-Schafer, 281
Lichen Dyes, Miss F. Haworth, 620
Lichens: A New Family of, Miss A. Lorrain Smith, 33; Isidia and Soralia of, O. V. Darbishire, 33
Life, The Unity of, Prof. C. J. Patten, 919
Light: and Electricity, Prof. E. N. da C. Andrade, 101; and Growth, 543; diffused by Benzene in the Liquid State, The Absolute Measurement of the Intensity of the, J. Cabannes and P. Daure, 546; Filters, Measurements of Absorption Coefficients of, Dr. G. M. B. Dobson and I. O. Griffith, 585; Magnetic Dispersion of, The Constants of the, Prof. C. G. Darwin and W. H. Watson, 412; Quanta, The Length of, Dr. G. Breit, 280; The Nature of, Prof. E. B. Wilson, 615; Treatment in Surgery, Dr. O. Bernhard, 701; Velocity of, New Determinations of the, Dr. A. A. Michelson, 794
Lightning, Progressive: Dr. C. D. Perrine, 278, 816; Prof. C. V. Boys, 279, 816
Ligniera: Junci, Influence of Environment on, W. R. I. Cook, 657; The Genus, W. R. I. Cook, 33
Lignin and Lignification, C. F. Cross, 5
Lignins, Die Chemie des, Dr. W. Fuchs, 5
Lilium longiflorum, An Important Virus Disease of, and its Varieties, L. Ogilvie, 528
Lime: in Agriculture, 1: in Plant Nutrition, 2: in Animal Nutrition; a Handbook for Practical Farmers, Students, and others, F. E. Corrie, 313; on the Farm, 683
Limestone containing Lepidocyclina and other Foraminifera, from the Cape Range, Exmouth Gulf, Western Australia, On a, F. Chapman, 514
Limit, The Deferred Approach to the, Dr. L. F. Richardson, 181
Limnæa: peregra, The Origin of an Albino Mutation in, Prof. A. E. Boycott and C. Diver, 9; Life-history and Distribution of, Dr. C. L. Walton and W. N. Jones, 332
Limnology, International Congress of Theoretical and Applied, Forthcoming, at Rome, 577
Limnoria, The Absence of a Cellulase in, Dr. C. M. Yonge, 855
Linnæus, Carl, the 220th anniversary of the birth of, 756
Linnean Society: award of the Linnean gold medal to Dr. O. Stapf and the Crisp medal to Prof. H. G. Cannon, 649; election of officers; presentation of medals to Dr. O. Stapf and Prof. H. G. Cannon, 866; of N.S.W., Prof. L. Harrison elected president, 827
Liquid Fuels, The Utilisation of, containing a High Proportion of Organic Sulphur Compounds as a Source of an Antidetonating Combustible, Y. Altchidjian, 71
Lister: and Physiology, Sir C. S. Sherrington, 606, Centenary Celebrations in London, The, 570
Lister's: Contribution to Preventive Medicine, Dr. C. J. Martin, 529; Scientific Work, Some Aspects of, Prof. W. Bulloch, 531
Liver Oils, Colour Reactions associated with, W. R. Fearon, 145
Livingstone College, Annual Report of the, 63
Logic and Law in Biology, Dr. P. Chalmers Mitchell, 721
London: A University Centre in, 764; City of, Area, Chronological Interpretation of Archæological Evidence in the, G. Hume, 249; School of Hygiene and Tropical Medicine, Second Annual Report of the, 62; The Stones of, J. Allen Howe, 537; University: The Laboratory of Civil and Mechanical Engineering at University to be named the Cowdray Laboratory, 219; the title of reader in geology conferred on G. McDonald Davies; conferment of doctorates, 219; conferment of the title of professor of psychology on Dr. Beatrice Edgell, 258; the title of reader in geometry conferred on J. L. S. Hatton, 411; W. E. Le Gros Clark appointed professor of anatomy at St. Bartholomew's Hospital Medical College; Dr. H. Hartridge appointed professor of physiology at St. Bartholomew's Hospital Medical College, 511; conferment of doctorates, 511; gift from A. Wander, Ltd.; D. MacC. Blair appointed professor of anatomy at King's College; Dr. G. S. Wilson appointed reader in bacteriology and immunology at the London School of Hygiene and Tropical Medicine; conferment of doctorates; award of the Dunn exhibitions in anatomy and physiology to K. M. Robertson, 799; Report for 1926–27, 876; *Weekly, The*, 97
Long-chain: Compounds, An X-ray Investigation of certain, Dr. A. Muller, 301; Organic Compounds, The Various Crystalline Forms of, and the Difficulties of Interpretation of their X-ray Spectra, J. Thibaud, 263
Loutreuil Foundation of the Paris Academy of Sciences, 178
Low Temperature Carbonisation: 333; Retort, 27
Lower Old Red Sandstone Plants showing Structure, from Brecon, On, A. Heard, 34
Luciola gorhami, Origin of Yolk in the Egg of, Prof. V. Nath and Dev Raj Mehta, 13
Lumbricus, The Oogenesis of, L. A. Harvey, 14
Luminescence: due to Radioactivity, D. H. Kabakjian, 659; in Radioactive Luminous Compound, The Theory of, J. W. T. Walsh, 878
Lunar Eclipses of 1927, The, 655
Lythrum salicaria, Inheritance of Trimorphism in, E. M. East, 839

Macaulay (J. M.), 'Seizure' with Sliding Surfaces, 425
Madeira, The Garden Interests of, Dr. M. C. Grabham, 683
Madi Rainstones, F. H. Rogers, 868
Madras Government Museum, Report of the, 172
Magmatic Differentiation, C. N. Fenner, 295
Magne-crystallic Action, Tyndall's Experiments on, Sir William Bragg, May 7, Suppt., 61
Magnesium: -Copper Alloys, Dr. M. Hansen, 653; -rich Magnesium-copper Alloys, The, Dr. M. Hansen, 585
Magnet Galvanometers, Moving, Dr. C. V. Drysdale, 941
Magnetic: Dip in Geological Time, Reversal of, P. L. Mercanton, 580; Disturbances observed at Parc Saint-Maur and at Val-Joyeux, The Periodicity of the, C. E. Brazier, 547; Double Refraction, Prof. C. V. Raman and J. Rama Krishna Rao, 528; Induction in Continuous Media, C. R. Burch and N. R. Davis, 353; Moment of the Electron? Is it possible to detect directly the, L. Brillouin, 302; Observations made by the Ordnance Survey in the Channel Islands in 1925, etc., Results of the, 611; Observatory at

Matochkin Shar (Novaya Zemblya), The, 97; Research, Dr. E. C. Stoner, 762; Storms, The Law of Distribution of, and of their Elements, Dr. H. Deslandres, 221
Magnetism: and Atomic Structure, Dr. E. C. Stoner, 809; The Future of, Dr. P. Kapitza, 809
Maiao (Society Islands), The Geology of, L. J. Chubb and W. Campbell Smith, 585
Maize, Dormant, Genetics of, 652
Malayo-Polynesians in America, Dr. P. Rivet, 332
Man: and Weather, Prof. A. McAdie, 274, not a Machine: a Study of the Finalistic Aspects of Life, Prof. E. Rignano, 738
Man's Place of Origin, Dr. W. K. Gregory, 939
Manchester: Literary and Philosophical Society, election of officers, 794; University: resignation of Prof. W. W. C. Topley; W. O. Howarth appointed to supervise research in mycology; H. G. Chippindale appointed research assistant in mycology, 372; Prof. H. S. Raper appointed dean of the Medical School; award of the Hill prize in bio-chemistry to E. Boyland, 476; Dr. A. M. Smith appointed lecturer in agricultural chemistry, etc., 544; anonymous gift for post-graduate scholarships, 764
Mandshurian Tiger, The, 138
Manganese: Dioxide in the Solid State, Reactivity of, F. De Carli, 414; Pyrophosphate, The Magnetic Properties of, at Various Temperatures, G. Foex and Mlle. A. Brunet, 513
α-Manganese, The Crystal Structure of, A. J. Bradley and J. Thewlis, 877
Manoilov Reaction for the Identification of Sex and its Application to the Case of the Sexually Abnormal Fowl, The, Miss J. S. S. Blyth, 261
Manson, Sir Patrick, A memorial plaque to, 400, 468
Maori: Canoe, The, E. Best, 297; Games, E. Best, 795; Navigation, S. H. Ray, 297; Symbolism: being an Account of the Origin, Migration, and Culture of the New Zealand Maori, as recorded in Certain Sacred Legends, Report made by Ettie A. Rout, 386
Map Projections, An Introduction to the Study of, J. A. Steers; J. E. Coleclough, 888
Marine Biology: at the Isle of Man, 213; in the Pacific, 404; *Observer*, The, Jan., 172; Observers' Handbook, fourth edition, 648, Shells of the W. Coast of N. America, 26, Steam Turbine Progress, Hon. Sir Charles Parsons, R. J. Walker, and S. Cook, 176; Works: a Practical Treatise for Maritime Engineers, Landowners and Public Authorities, E. Latham. Second edition, 741
Mars: Axis of, The Position of the, 820; Photographs of, in 1926, F. E. Ross, 252; Photographs of, R. J. Trumpler, 938; Satellites of, A. Hall, E. C. Bower, and Miss E. A. Lamson, 137; The Planet, Jarry-Desloges, 106
Mass-spectrograph, A New, and the Whole Number Rule, Dr. F. W. Aston, 945
Maternal and Paternal Heredity in the Capacity for Larval Development of the Reciprocal Crosses between Two Races of Silkworms, C. Jucci, 623
Mathematical Models, List of, G. Cussons, Ltd., 905
Matières colorantes organiques, La Chimie des, Dr. P. Casten, Mar. 5, Suppt., 7
Matrix and Wave Mechanics, R. H. Fowler, 239
Matter: and Gravity in Newton's Physical Philosophy: a Study in the Natural Philosophy of Newton's Time, A. J. Snow, 454; and Radiation, The Equilibrium between, P. Langevin, 622; and Electricity, A Theory of, G. D. Birkhoff, 839; The Creation of, Dr. A. Haas, 296
Mawken Canoe in Algoa Bay, A, F. W. FitzSimons, 746
Maxwell, Clerk, and the Cavendish Laboratory, Sir Oliver Lodge, 46
Maxwell's Equations and Atomic Dynamics, A. Bramley, 338
Maya: Exploration Fund, Appeal for a, 135; Ruins in Yucatan, Report on, Dr. T. W. Gann, 723
Meccanica razionale, Lezioni di, Profs. T. Levi-Cività e U. Amaldi. Volume secondo. Parte prima, 485
Mechanism and Vitalism, 738
Median Pré-Alps, The Lias of the, E. Peterhans, 940
Medical: and Veterinary Entomology in Australia, E. W. Ferguson, 947; Education: and Registration, Dr. H. H. Dale appointed a member of the general council of, 681; Methods and Problems of: 68; Fifth series, 251; Examination before Marriage, Should a, be Obligatory? Dr. G. Schreiber, 436; Report of the Hamilton Rice Seventh Expedition to the Amazon, in Conjunction with the Dept. of Tropical Medicine of Harvard University, 1924–1925, 885; Research Council, Activities of the, 497
Melanism in the Lepidoptera, The Induction of, and its Evolutionary Significance, Dr. J. W. Heslop Harrison, 127, 318
Melilite-spurrite-Ca_2SiO_4 Assemblage from Larne (Antrim), C. E. Tilley, 586
Mellon Institute of Industrial Research, Work of the, 577
Memory Factor in Biology: The, a Sketch of the Unity of Life, Prof. C. J. Patten, 741
Memphis, The Floods at, S. R. K. Glanville, 813
Mental Abilities, Correlation Coefficients and the Theory of, J. R. Thompson, 705
Menthol, De-hydrogenation of, New Process of, G. Cusmano, 107
Menthones and Derived Substances, Prof. J. Read and Dr. G. J. Robertson, 100
Mercury: Absorption Spectrum of, Bands in the, Lord Rayleigh, 778; -arc Power Rectifier, The, 176; Atoms, Excited, Photosensitised Decompositions by, Prof. H. S. Taylor and J. R. Bates, 339; Band Spectrum of Long Duration, Studies of the, Lord Rayleigh, 801; derived from Coal Tar, The Constitution of, Dr. F. W. Aston, 489; Free, in Commercial Products, The Determination of, H. B. Dunnicliff and Kishen Lal, 690; from the Excited Vapour, The Band Spectrum of, Lord Rayleigh, 387, 423; in the Extreme Ultra-Violet, The Spark Spectrum of, G. Déjardin, 221; into Gold, The Attempted Change of, Sheldon and Estey, 215; Krypton and Xenon, New Study of some Radiations of, from the Point of View of their Meteorological Applications, A. Pérard, 622; The Photo-electric Properties of, H. K. Dunn, 941; Vapour Trap, An Improved, G. I. Finch, 856
Mercury: as an evening star: 252; C. Schoch, 505; observed in Babylon, C. Schoch, 252
Mesoplodon bidens, The Oil of, E. André and H. Canal, 106
'Meta' Thorium Oxide, Peptisation of, G. R. Levi and A. Reina, 691
Metal Crystals, The Transverse Thermo-electric Effect in, P. W. Bridgman, 730
Metallic: Catalyst, Absolute Surface Area of a, A New Method of Measuring the, Dr. F. H. Constable, 349; Colloids, A General Method of Preparation of, E. Fouard, 446; Combinations, The Thermal Expansion of, M. de Hemptinne, 916; Compounds, The Electrical Properties of Some, H. André, 658; Crystals, Twin, The Formation of: G. D. Preston, 600; L. W. McKeehan, 120; Prof. H. C. H. Carpenter and S. Tamura, 121; Salt, Optically Active Complex, A Novel Type of, F. G. Mann and Sir W. J. Pope, 351; Single Crystals, Etch Planes in, H. H. Potter and W. Sucksmith, 924; Sulphides, The Action of High Temperatures on some, Picon, 302
Metallurgical Specimens, The Best Method of Illuminating, C. Beck, 766
Metallurgy, Some Recent Services of, to Engineering, Prof. H. C. H. Carpenter, 927
Metals: at Low Temperatures, Resistance of, 215; Colouring of, by Polishing, J. A. Wasik, 762; Fatigue of, in the Presence of Chemicals, G. D. Lehmann, 581; Institute of, The May Lecture of the, Sir Henry A. Miers, 758; Minerals and, of the British Empire, 625; Molten, The Attack of, on Certain Non-ferrous Metals and Alloys, H. J. Hartley, 584, Viscosity of, Dr. F. Hettwer, 140
Meteor, The Detonating, of Oct. 2, 1926, F. J. Whipple, 578
Meteoric Iron Block from Savik at Cape York, The, O. B. Bøggild, 262
Meteorites: The Composition of, G. P. Merrill, 508; The Origin of, R. Schwinner, 796

Meteorological: Observations made at Sea, Some, N. K. Johnson, 145; Perturbations of Tides and Currents in an Unlimited Channel Rotating with the Earth, H. Horrocks, 337
Meteorology: Ancient and Modern, W. H. Dines, 915; and Air Routes, 256; Elementary, A Short Course in, W. H. Pick. Second edition, 274; Manual of, Vol. I.: Meteorology in History, Sir Napier Shaw, with the assistance of Elaine Austin, 915
Methane, Ignition of, by Spark Discharge, H. F. Coward and E. G. Meiter, 616
Metropolitan Asylums' Board, New Laboratories of the, opened by Mr. Neville Chamberlain, 724
Mexico, Valley of, The Archæology of the, Mrs. Zelia Nuttall, 472
Mica, G. V. Hobson, 653
Michelson-Morley Experiment: Another Repetition of the, R. J. Kennedy, 64; Realisation of the, in a Free Balloon, A. Piccard and E. Stahel, 414
Micro: -crystals in Electrolytically Deposited Silver, H. Hirata and H. Komatsubara, 334; Fauna of the Sea-bottom, An Apparatus for Catching the, Dr. T. Mortensen, 138
Micromagnetic Oscillations at Zouy, A. Podder, 369
Microphone, The, as a Detector of Small Vibrations, E. H. Booth, 303
Microscope Object-glasses, Demonstration of Beck's, 24
Microscopes and Accessories, Catalogue of, J. Swift and Son, Ltd., 63
Microscopic and Ultra-microscopic Objects, Control Experiments for a New Interferometric Method for the Measurement of, G. de Mottoni, 222
Microscopy: Practical, an Introduction to Microscopical Methods, Dr. F. S. Scales. Third edition, 557
Middle American Archæological Research, Dr. S. G. Morley, 579
Milk, Clean, The Production and Distribution of, A. T. R. Mattick, 828
Milky Way, Beyond the, Dr. G. E. Hale, 888
Milton Chantry, Proposed Reconstruction of, 329
Mind and Body, Types of, Dr. E. Miller, 702
Mineral: Compounds, Chemical Formulæ of, L. W. Tibyriçá; J. W. E., 815; Fields: The Location of, Modern Procedure in the Investigation of Mineral Areas and the Subsequent Verification of their Extent, etc., M. H. Haddock, Mar. 19, Suppt., 13; Resources of the British Empire, Proposed Review of the, Sir Thomas H. Holland, 640
Mineralogie, Lehrbuch der, Prof. P. Niggli. 1. Allgemeine Mineralogie. Zweite Auflage. 2. Spezielle Mineralogie. Zweite Auflage, 595
Mineralogists, recently deceased, Biographical Notices of, Dr. L. J. Spencer, 586
Mineralogy, General and Special, 595
Minerals and Metals of the British Empire, 625
Mining: and Metallurgy, Institution of, Awards of the, 505; Law in the Empire, Observations upon, G. Stone, 646
Minorca, Prehistoric Monuments in, F. Chamberlain, 61
Mississippi Floods: The, 680; Dr. D. E. White, 940
Mitosis *in vitro*, The Effect of Radium on, R. G. Canti and M. Donaldson, 144
Modifiability, A Fundamental Theorem in, E. L. Thorndike, 659
Modified Scattered X-Radiation due to Super-position, Prof. C. G. Barkla, 778
Moens Klint and Lonstrup, Denmark, The Structure of the Disturbed Deposits of, G. Slater, 181
Mohammedan Child-killing Demons, W. Ivenow, 26
Moisture, The Determination of, by the Volatile Solvent Method, J. M. Jones and T. McLachlan, 836
Molecular: Beams, Intensities of, T. H. Johnson, 745; Complexity, Experiments on, Prof. H. B. Baker, 510
Mollusca, New, from Mexico, Central and South America, 254
Molybdenum: in Nickel-chrome Steels, 685; the Volumetric Estimation of, A New Method for, G. Denigès, 446
Money, The Mystery of, Prof. F. Soddy, 46; W. H. Coates, 47
Mongrel Virginians: The Win Tribe, A. H. Estabrook and I. E. McDougle, 812
Monilia fructigena, Zonation in Cultures of, Miss M. P. Hall, 657
Mono-Alu Folklore (Bougainville Strait, Western Solomon Islands), Dr. G. C. Wheeler, 386
Monoethyl Aspartate, Aqueous Solutions of, Natural Refractive and Rotatory Dispersion of, M. L. Pagliarulo, 911
Monotreme, Milk of the, H. R. Marston, 295
Moon's Shadow, The, in Relation to the Earth on June 29, Dr. E. H. Rayner, June 18, Suppt., 97
Moravia, Rainfall of, Dr. Fr. Rikovsky, 214
Mosquito Nuisance, Judicial Decision in Scotland on the, 934
Mount Girnar, Igneous Rocks of, M. S. Krishnan, K. K. Mathur, V. S. Dubey, and N. L. Sharma, 254
Mouse, Changes in the Ovary of the, following Exposure to X-rays: Dr. F. W. R. Brambell, Dr. A. S. Parkes, and Una Fielding, 144; Drs. F. W. R. Brambell and A. S. Parkes, 445; Ovarian Regeneration in the, after Complete Double Ovariotomy, Dr. A. S. Parkes, Una Fielding, and Dr. F. W. R. Brambell, 445
Muller-Pouillets Lehrbuch der Physik. Elfte Auflage. Herausgegeben von A. Eucken, O. Lummer, und E. Waetzmann. Band 2. Erste Halfte. Band 3. Erste Hälfte, Mar. 5, Suppt., 6
Muscle, The Viscous Elastic Properties of, Dr. A. Levin and J. Wyman, 445
Mutarotation and the Alkalinity of the Medium, H. Colin and Mlle. A. Chaudin, 658
Mycology in Great Britain, 256
Mytilus, The Ciliated Cells of the Gill of, D. Bhatia, 405

Naga Hills Celt, A, J. H. Hutton, 374
Nakuru, Discovery of a Human Skeleton at, L. S. Leakey, 61
Nanson Preferential Majority System of Election, The Technique of the, J. M. Baldwin, 35
Naparima: District of Trinidad, Tertiary Foraminifera from the, W. L. F. Nuttall, 302; Region of Trinidad, The Geology of the, V. C. Illing, 302
Naphthalene and of Anthracene, The Hydrogenation of, at a High Temperature and under High Pressure in the Presence of Non-hydrogenating Catalysts, A. Kling and D. Florentin, 690
Nassau Mountains, The Pygmies of the, Dr. Stirling, 249
National: Broadcasting Company of America, The Activities of the, A. Dinsdale, 901; Museum of Wales, gift to the, by Lord Buckland, 97; Physical Laboratory: Collected Research of the. Vol. 19, 937; visit of the Illuminating Engineering Society to the, 724; Progress, Trusts and, 140; Union of Scientific Workers: Appeal of the: 327; A. G. Tarrant, 436; J. B. Ward, 647; change of name to The Association of Scientific Workers, 792
Natives Think, How (Les Fonctions mentales dans les sociétés inférieures), Prof. L. Lévy-Bruhl. Translated by Lilian S. Clare, 700
Natural: -colour Photography under the Sea, Dr. W. H. Longley and C. Martin, 365; *History Magazine*, No. 1, 401; History: Museum, South Kensington, The Future of the, Sir E. Ray Lankester, 314; Museums, The Development of: 549; Dr. F. A. Bather; The Writer of the Article, 639; Man: a Record from Borneo, Dr. C. Hose, 806; Selection, Larger Aspects of, Prof. T. D. A. Cockerell, 564
Nature, The Preservation of, Dr. J. Ritchie, 265
Naturen, completion of its fiftieth year, 291
Navaho Grammar, A Manual of, arranged by Fr. B. Haile, 668
Nebalia bipes, The Feeding Mechanism of, Prof. H. G. Cannon, 803
Nebulæ, Great, The Genesis of the, Dr. J. H. Jeans, 315
Negroes in the U.S., Colour Selection among, J. Herskovits, 213
Neon: Ionised, Regularity in the Spectrum of, P. K. Kichlu, 671; (Ne II), Ionised, The Spectrum of, T. L. de Bruin, 925; Lamp, Relighting of a, when momentarily extinguished at Voltages below the Striking Potential, R. R. Nimmo, 586; Spectrum, Hyperfine Structure in the, Dr. G. Hansen, 237

Neptune, The Planet, M. E. J. Gheury de Bray, 293
Nerves and Muscles: How we feel and move, Prof. A. V. Hill, 284
New: Brunswick, Devonian Volcanic Rocks of, W. V. Howard, 99; Caledonian Art, G. H. Luquet, 760; Education Fellowship, forthcoming world conference arranged by the, 103; Guinea: An Exploring Expedition in, 827; Rest Periods in, Prof. C. G. Seligman, 506; The Expedition of the Smithsonian Institution and the Scientific Research Society of the Dutch East Indies to, 135; Year Honours, 59; Zealand Annual Report of Lands and Survey, 291; Kauri (*Agathis australis*), An Examination of Defective, M. B. Welch, 303
Newton: Celebration, forthcoming, in New York, 900; Commemoration, The, 467 and Suppt., Mar. 26; Dwelling-places, Portraits, and Medallic Illustrations of, T. E. James, 465; Isaac: Dr. J. H. Jeans, Mar. 26, Suppt., 28, fund for a scholarship in memory of, 575
Newton's: Death, The Bicentenary of, Bishop of Birmingham, Mar. 26, Suppt., 21; Moving Water Rings, White Spot with, Prof. J. Muir, 781; Work: in Astronomy, Sir Frank Dyson, Mar. 26, Suppt., 30; in Mechanics, Prof. H. Lamb, Mar. 26, Suppt., 33; in Optics, Sir Richard Glazebrook, Mar. 26, Suppt., 43; in Pure Mathematics, Prof. L. J. Mordell, Mar. 26, Suppt., 40; in Physics, Sir J. J. Thomson, Mar. 26, Suppt., 36; Place in Science, F. S. Marvin, Mar. 26, Suppt., 24
Newtonian Time essential to Astronomy, Sir Joseph Larmor, April 9, Suppt., 49
NH Compounds, The Spectra of, Dr. E. Hulthén and S. Nakamura, 235
Niccolite and Ullmannite at the Settlingstones Mines, Fourstones, Northumberland, etc., Occurrence of, A. Russell, 261
Nigeria: Agriculture in, 796; Mr. Ormsby-Gore, 469
Nilotic Tribe, The Life of a, Mrs. Brenda Z. Seligman, 113
Nimrud Volcano, Armenia, Alkaline Rocks from, Dr. G. T. Prior, 586
Nineteenth-Century Teacher, A, John Henry Bridges, M.B., F.R.C.P., sometime Fellow of Oriel College, Oxford, and late Medical Inspector to the Local Government Board, Susan Liveing, 116
Nitric Oxide, The β Bands of, F. A. Jenkins, H. A. Barton, and Dr. A. S. Mulliken, 118
Nitrogen: Absorption Bands in, H. Sponer, 838; Active: Dr. R. C. Johnson, 9; Dr. E. J. B. Willey, 924; and Carbon Monoxide, A Comparison of the Behaviour in Thermal Diffusion of, and of Nitrous Oxide and Carbon Dioxide, T. L. Ibbs and L. Underwood, 585; Formula of Blood Serum, Modifications brought about in the, by Renal Impermeability, F. Widal and M. Laudat, 105; Ionised, The Spectrum of (N II), Prof. A. Fowler and L. J. Freeman, 801; Pentoxide, Decomposition of, Dr. R. G. W. Norrish, 123; Peroxide, The Reaction of, with Sulphurous Anhydride, E. Briner, G. Lunge, and A. Mirimanoff, 262; The Density, Compressibility, and Atomic Weight of, G. P. Baxter and H. W. Starkweather, 339; to Steel, The Addition of, L. Guillet, 70
Nitroxyl, Reactions of, with Aromatic Nitro-derivatives and with Azoxy-compounds, D. Bigiavi, 222
Niue (Savage Island), E. M. Loeb, 579
"Nomenclator animalium, generum et subgenerum," 61
Non: -aqueous Solution, Organic Acids and Bases in, F. Holzl, 222; -marine Lamellibranchs of the Coal Measures, A Revision of the, and a Discussion of their Zonal Sequence, J. H. Davies and A. E. Trueman, 105
North Siberian Shelf, The Tides on the, H. U. Sverdrup, 763
Northern: Alberta, Bituminous Sands of, S. C. Ells, 66; Tungus Migrations, Prof. S. M. Shirokogoroff, 253
Norvège, Préhistoire de la, Dr. H. Shetelig, Mar. 5, Suppt., 1
Norway, Weather Conditions in, for the Eclipse of June 29, K. Kerdylewski and Z. Eckstein, 98
Norwegian Plankton Investigations, B. Rund, 472
Nuclear Degenerations due to Multipolar Mitosis, Dr. J. A. Murray, 413
Nutritive Salts, Influence of, on the Transpiration, Water Assimilation, Relative Shoot and Root Masses and Leaf Structure. Parts 1 and 2, T. Kisser, 767
Nyasan Rift-valley, The Tertiary and Post-tertiary Lacustrine Sediments of the, Dr. F. Dixey, 181

Observatories' Year-Book, The, 1923, 663
Observer's Handbook for 1927, The, 293
Occultism, Modern, 187
Ocean Currents, Admiral Niblack, 831
Oceanographical Expeditions, Two, 18
Oceanography of the Baltic and Fishery Research, Prof. O. Petterson, 29
Oceans and Continents, M. Brillouin, 730
Odours and Visual Imagery, Dr. J. H. Kenneth, 818
Œnothera, Crossing over in the Third Linkage Group of, G. H. Shull, 659
Œstrous Cycle, On the Occurrence of the, after X-ray Sterilisation. Part II., Dr. A. S. Parkes, 144
Oil: Contamination as a Climatic Factor, L. A. Ramdas, 652; -fields, The Electrical Working of, 211; in Burma, Dr. L. D. Stamp, 333; Oil-Shale and Coal, The Geology of, Dr. M. Stuart, Mar. 19, Suppt., 13; Pollution of Navigable Waters, The Government and, 756; Prospects of the Battle River Area, Alberta, G. S. Hume, 831; Surveys in Northern Alaska, P. S. Smith, J. B. Mertie, and W. T. Foran, 130
Oils of Marine Animals, Some, The Heats of Combustion of, H. Marcelet, 587
Oiseaux: Les, l'ornithologie et ses bases scientifiques, Dr. M. Boubier, Mar. 5, Suppt., 2
Old Red Sandstone Flora of Scotland, The (vi.), Prof. W. H. Lang, 946
Oligochæte, A Polymorphic, Rev. Hilderic Friend, 281
Onnes Memorial Lecture, The, Prof. E. Cohen, 288
Opium in Stomach Contents, The Rapid Determination of, E. R. Dovey, 34
Optical: Convention, 1926: The, Catalogue of Optical and General Scientific Instruments, 383; *Proceedings* of the, 2 parts, 383; Fields, Some Uncultivated, T. Smith, 413; Glass, Optical Constants of, 100; Society: election of officers, 365; *Transactions* of the, No. 5, 1925–26, 211
Orchids: Cultivated, Seedling Structure of, J. Ramsbottom and E. H. Ellis, 260; of Sikkim, A Guide to the, Prof. P. Bruhl, 851
Ore Dressing in Canada, 507
Organic: and Bio-chemistry, Practical, Prof. R. H. A. Plimmer. New edition, 811; Chemical Industry, The Romance of the, Dr. E. F. Armstrong, 289; Compounds, The Preparation and Analysis of, J. B. Coleman and Dr. F. Arnall, 851; Syntheses: an Annual Publication of Satisfactory Methods for the Preparation of Organic Chemicals. Vol. 5, 520, 668
Organo-magnesium Compounds: Action of, on Nitriles, P. Bruylants and A. Dewael, 414; and the Nitriles, The Reaction between the, F. Petit, 910; The Constitution of the, P. Jolibois, 71
Oriental Seals, I. M. Casanowicz, 294
Orientation of Churches, Rev. J. Griffith, 506
l'Ornithologie, L'Évolution de, Dr. M. Boubier, Mar. 5, Suppt., 2
Otology, Contributions to the Art and Science of, Lectures and Papers by Richard Lake, 1892–1925, 233
"Outline of History, The": Mr. Belloc objects to, H. G. Wells, 75; Mr. Wells's, Mr. Belloc still objects to, Hilaire Belloc, 75; Mr. Wells's, A Companion to, Hilaire Belloc, 75
Ovarian Grafts in the Male Mouse, Effects of Implantation upon, Y. Tamura, 621
'Overspeed' Test House, A New, Metropolitan Vickers Electrical Co., 290
Oxalic Acid, Pure, The Electrolysis of Aqueous Solutions of, E. Doumer, 658
Oxford: The Sir William Dunn School of Pathology, Opening of the, 433; University: A. G. Tansley appointed Sherardian professor of botany, 179; gifts to, 247; Profs. G. Bourne and S. Vines made emeritus professors; regulations for the Rolleston memorial prize, 258; establishment of a research fellowship in medical science in memory of Dr. G. I. Schorstein, 476; Statutes of; foundation of a memorial travelling studentship, 764; eligibility of women as professors,

etc.; the University observatory to be extended, 835; impending conferment of honorary doctorates, 875; Prof. A. M. Carr-Saunders appointed Herbert Spencer lecturer for 1928, 907; money grants to laboratories of certain colleges; an Aldrichian praelector in chemistry, 944

Oxidation-reduction, Potential, On the Mechanism of, M. Dixon, 145

Oxygen: and Nitric Oxide, The Theory of the Paramagnetism of, Prof. J. H. Van Vleck, 670; -carbon Dioxide Antagonism, J. Amar, 106; Compounds, A Method of High-temperature Electrolysis of, Andrieux, 302; The Density of, and its Compressibility below one Atmosphere, G. P. Baxter and H. W. Starkweather, 339; $=17.O\phi$, Prof. H. E. Armstrong, 51

Oyster, European, Researches on Sex-change in the, Dr. J. H. Orton, 177

Ozone: Formation of, by the Silent Electric Discharge in the Presence of Foreign Gases, A. Juliard, 910; Formation, The Kinetics of, under the Action of the α-particles, W. Mund and J. d'Olieslager, 373; in the Earth's Atmosphere, Measurements of, and its Relation to other Geophysical Conditions. Part II., Dr. G. M. B. Dobson, D. N. Harrison, and J. Lawrence, 337; in the Presence of Hydrogen, Thermal Decomposition of, R. O. Griffith and K. McKeown, 255

p-Xylyl-allylacetic Acid and its Conversion into Cyclic Tetra-hydronaphthalene Derivatives, G. Darzens and A. Heinz, 262

Pacific, Tropical Cyclones of the, E. V. Newnham, 218

Palæolithic Man in Scotland, 475

Palestine, Proposed Italian Geographical Studies in, 96

Pan: -American Child Congress, Impending, at Havana, 583; Pacific Science Congress, The Third, 178

Parabromobenzyl Chloride and the Grignard Reaction, R. Quelet, 730

Paraffin Imbedding Blocks, A New Apparatus for Casting, M. T. Deane, 70

Paragonimus, A New Species of, A. Gulati, 580

Paramagnetism Independent of Temperature, Mlle. Paule Collet, 106

Parasites: and Man, 885; Liquid of, The Molecular Concentration of the, W. H. Schopfer, 514

Paris: Academy of Sciences: Loutreuil Foundation of the, 178; prizes and grants awarded in 1926, 141; University of, course of anthropology in the, 63

Parsons, William, Third Earl of Rosse, 1800–1867, The Scientific Papers of, Collected and republished by the Hon. Sir Charles Parsons, 627

Pastures, The Correlation of Nutritive Value with Dry Matter Content of, E. J. Sheehy, 586

Pathological Sera (Cancer, Syphilis, Tuberculosis), A Method of Differentiation of, R. Douris and G. Giquel, 587

Paths that do not separate a Given Continuous Curve, Concerning, R. L. Moore, 339

Pearl Shells, Peculiar, E. A. Chapman; Prof. W. J. Dakin, 864

Pearls, Structure of, C. Amirthalingam, 854

Peas: Garden, Linkage in, Miss Sverdrup, 473; Pollination Experiments with, Dr. C. J. Bond, 541

Pedestal Rocks formed by Erosion, K. Bryan, 684

Penicillium glaucum, The Influence of Calcium on, H. Coupin, 658

Penrose's Annual: the Process Year Book and Review of the Graphic Arts. Edited by W. Gamble. Vol. 29, 1927, 274

People of the Veil: being an Account of the Habits, Organisation and History of the Wandering Tuareg Tribes which inhabit the Mountains of Air or Asben in the Central Sahara, F. Rennell Rodd, 551

Peperite, Existence in the South of Annam of a, resulting from the Intrusion of a Basalt into a Diatomaceous Sediment, A. Lacroix and F. Blondel, 946

Perception, The Theory of, An Introduction to, Sir J. H. Parsons; Prof. T. Graham Brown, 773

Periodic Orbits of the Second Genus near the Straight-line Equilibrium-points in the Problem of Three Bodies, D. Buchanan, 180

Perkin medal, J. E. Temple awarded the, 577

Pestalozzi: and the Teaching of Science, 377; The Greatness of, and its Numerical Evaluation, E. Claparède, 514

Petrographic Notes on Specimens in the 'David Forbes' Collection of Rocks in the Manchester Museum, G. Andrew, 767

Petroleum in Persia, Sir John Cadman, 762

Pflanzenanatomie, Handbuch der, Herausgegeben von Prof. K. Linsbauer. Abt. 1, Teil 2, Band 4; Band 5, 628

Pflanzenareale: Die, Sammlung kartographischer Darstellungen von Verbreitungsbezirken der lebenden und fossilen Pflanzen-Familien, -Gattungen und -Arten, Prof. L. Diels und Prof. G. Samuelsson. 1 Reihe, Heft 1 und Heft 2, Mar. 5, Suppt., 5

*p*H; Malic Acid, The Rotatory Power of Organic Substances as a Function of the, E. Vellinger, 302

Phaseolus vulgaris, The Presence of Allantoic Acid in, R. Fosse, 146

Phenacite, Be_2SiO_4, The Structure of, Prof. W. L. Bragg, 181

Phenols, The Transformation of the, into Hydrocarbons, in the Presence of Catalysts and Hydrogen under Pressure, A. Kling and D. Florentin, 730

Phenylmagnesium Bromide, Action of, on the Trisubstituted Acetonitriles, Mme. Ramart-Lucas and F. Salmon-Legagneur, 302

Philippine Islands, Weapons and Armour of the, H. W. Krieger, 540

Philippines, Polychæta from the, A. L. Treadwell, 473

Philosophy and Physics, Dr. J. H. Tummers. 440

Phosphates in Calcareous Silos, Estimation of, S. Das, 176

Phosphorus in Muscular Contraction, The Significance of, P. and M. G. Eggleton, 194

Photo: -electric: Emission, Thermionic Emission, and Peltier Effect, E. H. Hall, 730; Polarimetry, Prof. H. von Halban, 86; Thresholds, The Periodicity of, G. B. Welch, 838; -electrons, The Energy of, produced by soft X-rays, E. Rudberg, 704; -micrography, Practical, J. E. Barnard and F. V. Welch. Second edition, 313

Photographic: Image, Density of the, Dr. E. A. Baker, 685; Impressions, Influence of Temperature on, G. Colange, 946; Negatives, Pinholes in, Capt. C. J. P. Cave, 852; Plate, The Law of Blackening of the, at Low Densities, Second paper (iv.), E. A. Baker, 105; Plates, The Calibration of, F. S. Hogg and Cecilia H. Payne, 925; Telescope, A New Type of, A. Couder, 182

Photography, The American Annual of, 1927. Vol. 41, edited by F. R. Fraprie and E. J. Wall, 80

Photosynthesis, H. A. Spoehr, 808

Phylogeny and Classification, Dr. W. B. Crow, 26

Physical: and Chemical: Constants: Tables of, and Some Mathematical Functions, Dr. G. W. C. Kaye and Prof. T. H. Laby. Fifth edition, 193; Dr. Ezer Griffiths, 735; and Optical Societies, Annual Exhibition of the, 101; Society of London, election of officers, 330; World, The Nature of the, Prof. A. S. Eddington, 170

Physiciens hollandais, Les, et la méthode expérimentale en France au XVIII^{e} siècle, Prof. P. Brunet, 812

Physico-chemical Periodicity, The Problem of, Dr. E. S. Hedges and Dr. J. E. Myers, 267

Physics: General, for the Laboratory, Prof. L. W. Taylor, W. W. Watson, and Prof. C. E. Howe. Mar. 19, Suppt., 15; Institute of: Annual Report for 1926, 793; election of officers, 758; resignation of Prof. A. W. Porter of the honorary secretaryship; appointment of Prof. A. O. Rankine as successor and of T. Martin as secretary, 96; in the Glass Industry, Prof. W. E. S. Turner, 825; German Handbooks of, 189; of the Earth, British members of committees on the, 504; Practical, Notes on, for Junior Students, Prof. C. G. Barkla and Dr. G. A. Carse. Second edition, Mar. 19, Suppt., 15

Physik, Handbuch der, Herausgegeben von H. Geiger und K. Scheel. Band 1: Geschichte der Physik; Vorlesungstechnik, Redigiert von K. Scheel, 189

Physikalische Mediumismus, Der, Dr. W. v. Gulat-Wellenburg, Graf Carl v. Klinckowstroem und Dr. H. Rosenbusch, 187

Physiological Society, Jubilee dinner of the, 756
Physiology, Recent Advances in, Prof. C. Lovatt Evans. Second edition, 596
Physique, Cours de, à l'usage des élèves de l'enseignement supérieur et des ingénieurs, Prof. J. Becquerel. Tome 2, 850
Pigeons, Chromosomes of, K. Oguma, 869
Pigments, Paints, and Varnishes, The Analysis of, Dr. J. J. Fox and T. H. Bowles, 849
Pimpinellas of Tropical Africa, C. Norman, 260
Pinhole Probe Experiments with Massive Air Columns, Dr. C. Barus, 838
Pistil of Some Plants, The Preferential Electric Conductivity of the, S. C. Guha, 587
Pitman's "Radio Year Book," 1927, 97
Pituitary Body, The Comparative Anatomy, Histology, and Development of the, G. R. de Beer, 420
Planaria, Grafting in, Prof. H. W. Rand and Amy Browne, 253
Planets: and Periodicities, Dr. Z. Kamerling, 298; Ellipsoidal Stratification of the, The Impossibility of an, P. Dive, 622; The Minor, Prof. H. N. Russell, 137; The Stratification of the, and Fredholm's Equation, R. Wavre, 587
Plant: Activities, The Chemistry of, 808; Autographs and their Revelations, Sir J. C. Bose, 919; Geography, An Outline of, Dr. D. H. Campbell, 701; Lice or Aphididæ of Great Britain, The, F. V. Theobald. Vol. 1, 115; Nutrition and Crop Production, E. J. Russell (Sir John Russell), 454; Pathology and Disease Control, Landmarks in the Development of the Science of, Prof. P. A. van der Pijl, 67; Products, S. H. Collins and G. Redington, Mar. 19, Suppt., 11; Tissues: Electric Currents and, Prof. H. H. Dixon and T. A. Bennet-Clark, 580; Specialised, 628; The Electrical Stimulation of, Prof. H. H. Dixon and T. A. Bennet-Clark, 105
Plants: Inheritance in, Some Recent Advances in our Knowledge of, Prof. F. E. Weiss, 182; Organography of, Prof. K. von Goebel, 931; Physiology of Movement and Irritability in, The, Sir J. C. Bose, 209; The Presence in, of a Substance which becomes Luminescent in Ultra-violet Light, L. Petri, 690; The Story of the, Grant Allen. New edition, Mar. 19, Suppt., 10; with Milky Sap, Chemistry of, J. Zellner and others, 35
Plaster, Thermal Analysis of, An Apparatus for the, Jolibois and Chassevent, 373
Plato's American Republic, D. Woodruff, 455
Pneumokoniosis due to Asbestos Dust, W. E. Cooke and C. F. Hill, 766
Polar Pressures, L. C. W. Bonacina, 124
Polarisation: of a Medium, The, and its Molecular Structure, J. Errera, 373; of Light emitted by Positive Rays, E. Rupp, 100
Polarisationsmikroskop: Das, seine Anwendung in der Kolloidforschung und in der Farberei, H. Ambronn und A. Frey, Mar. 5, Suppt., 5
Polhem, Kristofer, The Work of, J. G. A. Rhodin, 22
Polishing of Surfaces, The: N. K. Adam, 162, 279; Dr. J. W. French, 527; Prof. J. Muir, 279; F. W. Preston; J. M. Macaulay, 13
Politician, The, and Political Economy, Dr. S. Evans, 67
Politics: and the Land, C. Dampier Whetham, 845; as a Science, Prof. H. J. Laski, 519; The Science and Method of, Prof. G. E. G. Catlin, 519
Pollen: Development in *Lathræa squamaria* and *L. clandestina*, Prof. R. R. Gates, 766; Utilisation of, by the Honeybee, R. L. Parker, 507
Pollution of Rivers and Estuaries, The, Lord Balfour, 327
Polonium: A New Determination of the Period of, M. A. da Silva, 373; The Penetration of, into Metals, E. Rona and E. A. W. Schmidt, 767
Polyatomic Molecule, The Quantisation of the Rotational Motion of the, by the New Wave Mechanics, E. E. Witmer, 731
Polyploids, The Behaviour of, C. D. Darlington, 390
Pontania salicis Christ., The Egg-laying Instincts of the Sawfly, Dr. J. W. H. Harrison, 220
Pontifical Academy of the Nuovi Lincei, Meeting of the, 172
Population and Migration, Sir Charles Close, 142
Porto Rico, Plant Ecology of, H. A. Gleason and M. I. Cook, 940
Positive Ions, a New Source of, Some Thermionic Experiments with, C. H. Kunsman, 338
Potash: a Review, Estimate and Forecast, Dr. J. W. Turrentine, 385
Potassium: Alum/hydrochloric Acid Solutions, The Effect of, on the Growth and Fate of Neoplastic Tissue (1), L. C. Strong, 839; Nitrate as a Fertiliser, 941
Potato: -breeding, Problems of, 271; Varieties, Dr. R. N. Salaman, 271; Virus Disease, Some Insect Carriers of, K. M. Smith, 145
Potatoes, Copper Dusts and Sprays for, O. C. Boyd, 761
Potentiometric Titrations: a Theoretical and Practical Treatise, Dr. I. M. Kolthoff and Dr. N. H. Furman, 346
Power: Station at Portishead, A Large, 470; Systems, Large, The Stability of, F. H. Clough, 364
Precision Pendulums, The Synchronisation at a Distance of, without Use of any Contact, P. Lejay, 446
Pre-Columbian Huastec Mounds in the Tampico Region, Mexico, J. M. Muir, 726
Prehistoric: Archæology in Yorkshire: O. G. S. Crawford, 494; T. Sheppard, 601; Man and the Cambridge Gravels, Rev. Frederick Smith, 523; Stone Implements, Sale of the Hewlett Collection of, 501
Preservatives Regulations, The New, E. R. Bolton, 546
Primary: Aberrations, On the Addition of the, G. C. Steward, 35; Cell, A New Type of, D. R. Barber, 892
Primitive: Culture in Italy, Prof. H. J. Rose, Mar. 19, Suppt., 9; Trade: its Psychology and Economics, Prof. Elizabeth Ellis Hoyt, 117
Prismatic Photographs, On Temperature and Pressure Regulation in, T. R. Merton, 181
Probabilités: Le calcul des, son évolution mathématique et philosophique, Prof. L.-G. Du Pasquier, 921
Professional Schools, etc., of Great Britain and Ireland, 1926–27, 336
Prominences, Two Interesting, F. da Costa Lobo, 302
Pro-œstrous Development in the Dog and Rabbit, The Effect of the Ovarian Hormone in producing, S. A. Asdell and Dr. F. H. A. Marshall, 220
Protective Mimicry in Insects, Prof. E. B. Poulton, 102
Proteins, Characterisation of Genuine, Prof. S. P. L. Sorensen, 369
Protistenkerne: Der Formwechsel der, eine vergleichend-morphologische Studie, Dr. K. Bělař, Mar. 5, Suppt., 4
Protoplasm, The Possible Production of, Sir Oliver Lodge, 902
Protoplasma, No. 1, 292
Protozoon, Larval Stages in a, M. M. Metcalf, 339
Proxima, Observations of, Innes and van den Bos, 25
Psychic Behaviour, Science and, Prof. H. Levy, 484
Psychical Research, The British Journal of. Vol. 1, No. 5, 484
Public: Analysts, Society of, election of officers, 436; Lighting by Electricity, Commdr. H. T. Harrison, 433
Publication: Organised, a Connected Series of Proposals relating to the Publication and Record of Scientific and Technical Information, J. F. Pownall, Mar. 19, Suppt., 19
Puzzle Crazes, H. E. Dudeney, 65
Pycnosende, The, Dr. D. la Cour, 369
Pyridine and the Pyridine Nucleus, The Oxidation with Permanganate of, M. Delépine, 373
Pyrosole: das kolloide Phanomen in der gluhend-flussigen Materie und seine Erstarrungszustande, Prof. R. Lorenz und Prof. W. Eitel, Mar. 5, Suppt., 7
Pyruvic Acid, A New Reaction of, T. Postarnak, 622

Quanta, The Theory of, On the Evaluation of certain Integrals important in, P. S. Epstein, 147
Quantenspringen durch Stösse, Anregung von, Prof. J. Franck und Dr. P. Jordan, Mar. 5, Suppt., 7
Quantum: Dynamics, The Physical Interpretation of the, P. A. M. Dirac, 181; Mechanics: Physical Aspects of, Prof. M. Born, 354; The Dielectric Constant and Diamagnetism of Hydrogen and Helium in the New, J. H. Van Vleck, 338; Theories, New, Prof. H. S. Allen, 77; Theory: and Gravitational Relativity, Prof. N. Wiener and D. J. Struik, 853; Modern Ideas

on the, H. T. Flint and J. W. Fisher, 477; New, The Correspondence Principle in the, C. Eckart, 338; Philosophical Foundations of: Dr N. R. Campbell, 779; Dr. P. Jordan, 566, 779; The Evolution and Development of the, N. M. Bligh, 193
Quarantine Signals for Ships, International, 212
Quarterly Review of Biology, No. 4, 538
Quartz: Fused, Dr. Berry, 250; Piezo-electricity of, L. H. Dawson, 870; The Fracture of, by Heat, B. W. Holman, 295
Quasi-unimolecular Reactions—the Decomposition of Diethyl Ether in the Gaseous State, C. N. Hinshelwood, 180
Quekett Microscopical Club, election of officers, 330

Rabbit: Natural Granular Conjunctivitis of the, C. Nicolle and V. Lumbroso, 878; Placenta of the, The Giant Cells in the, G. S. Sansom, 512
Rabbits, Artificial Insemination of, The Relation between 'Density' of Sperm-Suspension and Fertility as determined by, A. Walton, 445
Racemic Potassium Chlorosulpho-acetate, An X-ray Investigation of Optically Anomalous Crystals of, W. G. Burgers, 180
Racial Likeness, 40
Radcliffe: Infirmary, The, A. G. Gibson, Mar. 19, Suppt., 20; Library, The: etc., presented to the University of Oxford, 247; Lord Cottesloe, 350; The Writer of the Notes, 351
Radiation: and Matter, On the Equilibrium between, R. C. Tolman, 338; Emission and Absorption of, The Quantum Theory of the, P. A. M. Dirac, 338; from the Earth, Experiments on Highly Penetrating, L. N. Bogoiavlensky and A. A. Lomakin, 525; Intensity, Measurement of, by Photographic Methods, Dr. E. A. Baker, 707
Radiations: The Chemical Actions of, A. G. de Moncetz, 414; P. Villard, 478
Radio: -activity and the Heat of the Earth: Dr. J. W. Evans, 424; Dr. R. W. Lawson, 277, 703; Beam Service to Australia, The, 574; Communication, Progress of, 864; Frequency Measurements: The Theory and Practice of, a Handbook for the Laboratory and a Textbook for Advanced Students, E. B. Moullin, 155; in the Whaling Industry, 255; -receiving Sets from the Electric-lighting Mains, Apparatus required to operate, P. R. Coursey and H. Andrewes, 610; Reception and Solar Activity, G. W. Pickard, 437; Signals, Direction Changes and Fading in, H. J. Reich, 905; Telegraphy: and the Eclipse of the Sun, June 18, Suppt., 85; Short-wave, T. L. Eckersley, 401; -telephone Service between London and New York, Opening of the, 94; -telephony between London and New York, 60; Transmission, The Sun, the Earth's Atmosphere, and, Prof. S. Chapman, 428; -waves, Interference of, E. Quack, 870
Radioactive Substances, The Separation of, J. Kendall, E. R. Jette, and W. West, 296
Radium-B and Radium-C, The Absolute Intensities of the γ-rays of, C. D. Ellis and W. A. Wooster, 657
Raffles College, Singapore, Dr. G. McOwan appointed reader in chemistry at, 143
Rails, Internal Flaws in. Detection of, M. Suzuki, 255
Rain-drops, Sizes among, Distribution of, Prof. J. J. Nolan and J. Enright, 922
Rainfall, Average Monthly, Variability of, throughout the year, Dr. J. Glasspoole, 477
Raja, The Species and Sex-ratios of, Augusta Lamont, 651
Ranikot Beds of Thal (North-west Frontier Provinces of India), The, L. M. Davies, 105
Rare: Earth and Alkali Metals, Double Sulphates of, F. Zambonini and A. Stolfi, 222; Metals: Determination and Separation of, (ix.) Beryllium from Aluminium, L. Moser and M. Niessner, 691; from other Metals, Determination and Separation of the (viii.), L. Moser and A. Brukl, 107
Ray Society, election of officers, 539
α-Rays and β-Rays, The Passage of, through Matter, Dr. E. J. Williams, 459
Reading: Presentation of an Economic Botany Collection to, by Dr. J. B. Hurry, 292; University, conferment of an honorary doctorate on A. Palmer, 300
Reale Accademia Nazionale dei Lincei, Activities of the, Prof. Scialoja, 434
Reality: a New Correlation of Science and Religion, Rev. Canon B. H. Streeter, 273
Reciprocal Impenetrability of Matter and Pauli's Exclusion Principle, Relation between the, Prof. P. Ehrenfest: 196; A Correction, 602
Rectangular Beam, The, Loaded at a Point, Mesnager, 586
Red Cells of Man, The Diameter of the, before and after Exercise, E. Ponder, 802
Redi (F.), Tercentenary of the Birth of, 402
Refractive Indices of Mixtures, Calculation of the, and the Formulæ of Dieterici and Lichtenecker, E. van Aubel. 414
Refrigeration in the Chemical Industry, H. M. Dunkerley. 23
Regions of Compression, Dr. J. W. Evans, 15, 55
Rejuvenation, On, 396
Relative Variability, Graphic Comparison on, Prof. R. Pearl, 904
Relativity: and the Observer, Prof. H. Wildon Carr, 199; Fundamental Principles of, A Possible Way to discuss the, P. Slavenas, 339; Readable, a Book for Non-Specialists, C. V. Durell, Mar. 19, Suppt., 14; The General Theory of, 347
Religion, A New Approach to, 273
Research: Associations, The Financing of, R. W. Paul, 673; throughout the British Empire, Co-operation in, 661
Residual Thermal Phenomenon, A, Q. Majorana, 222
Resistance: of a Structure on a Reduced Model, Determination of the, Mesnager and Veyrier, 878; Standards, Four Terminal, The Measurement of the Inductances of, L. Hartshorn, 909
Resonance Radiation, A Source for, M. A. Tuve, 85

REVIEWS AND OUR BOOKSHELF.

Agriculture, Forestry, and Horticulture:
Agricultural Research in 1925, 312
Brühl (Prof. P.), A Guide to the Orchids of Sikkim: being a Guide to the Identification of those Species of Orchids found between the Terai and the Northern Frontier of Independent Sikkim, including the Chumbi Valley and British Bhutan, 851
Chandler (Prof. W. H.), Fruit Growing, Mar. 19, Suppt., 11
Chaturvedi (M. D.), Measurements of the Cubical Contents of Forest Crops: being a Critical Investigation into the Methods of Measuring Sample Plots, with special reference to the Liability to Error, 192
Corrie (F. E.), Lime in Agriculture. 1: in Plant Nutrition, 2: in Animal Nutrition, 313
Davis (R. A.), Citrus Growing in South Africa, 776
Emerson (Prof. P.), Soil Characteristics: a Field and Laboratory Guide, 596
Galt (A. S.), The Principles and Practice of Horticulture, Mar. 19, Suppt., 11
Grabham (Dr. M. C.), The Garden Interests of Madeira, 633
Handel-Mazzetti (Dr. H.), Naturbilder aus Sudwest-China: Erlebnisse und Eindrucke eines Osterreichischen Forschers wahrend des Weltkrieges, 667
Hansson (Prof. N.), Fütterung der Haustiere: ihre theoretischen Grundlagen und ihre wirtschaftliche Durchfuhrung. Übersetzt von F. von Meissner, 486
Malcolm (J.), Agricultural Surveying, including Mensuration, Road Construction, and Drainage, Mar. 19, Suppt., 12
Orwin (C. S.), and H. W. Kersey, Estate Accounts, Mar. 19, Suppt., 12
Russell (E. J.) [Sir John], Plant Nutrition and Crop Production, 454
Ruston (Dr. A. G.), and C. V. Dawe, Farm Calculations and Accounts, including a Thorough Treat-

ment of Agricultural Calculations and of the Business Transactions of the Farm, Mar. 19, Suppt., 12; Farm Measurements: a Practical Treatment of Problems in Mensuration, Mar. 19, Suppt., 12
Salaman (Dr. R. N.), Potato Varieties, 271
Turrentine (Dr. J. W.), Potash: a Review, Estimate, and Forecast, 385
Wagner (Dr. W.), Die chinesische Landwirtschaft, 698
Woodward (M.), The New Book of Trees, 742

Anthropology and Archæology:

Baikie (Rev. J.), The Amarna Age: a Study of the Crisis of the Ancient World, 851
Biometrika. Vol. 18, Parts 1 and 2, 40
Bouglé (Prof. C.), et J. Raffault, Éléments de sociologie: textes choisis et ordonnés, Mar. 5, Suppt., 1
Burkitt (M. C.), Our Early Ancestors: an Introductory Study of Mesolithic, Neolithic, and Copper Age Cultures in Europe and Adjacent Regions, 889
Estabrook (A. H.), and I. E. McDougle, Mongrel Virginians: The Win Tribe, 812
Gann (Dr. T. W.), Ancient Cities and Modern Tribes: Exploration and Adventure in Maya Lands, 631
Haile (Fr. B.), A Manual of Navaho Grammar, 668
Hambly (W. D.), Origins of Education among Primitive Peoples: a Comparative Study in Racial Development, Mar. 19, Suppt., 10; Tribal Dancing and Social Development, 488
Hauschild (Dr. M. W.). Grundriss der Anthropologie, Mar. 5, Suppt., 1
Hofmayr (Father W.), Die Schilluk: Geschichte, Religion und Leben eines Niloten-Stammes. Nach P. Banholzers F.S.C. und eigenen Aufzeichnungen dargestellt, 113
Hose (Dr. C.), Natural Man: a Record from Borneo, 806
Hoyt (Prof. Elizabeth Ellis), Primitive Trade: its Psychology and Economics, 117
Imbelloni (Prof. J.), La Esfinge Indiana: antiguos y nuevos aspectos del próblema de los origenes americanos, 3
Jardé (Prof. A.), translated by M. R. Dobie, The Formation of the Greek People, Mar. 19, Suppt., 9
Jones (N.), The Stone Age in Rhodesia, 226
Karsten (Prof. R.), The Civilization of the South American Indians: with special reference to Magic and Religion, 921
Ledroit (Prof. J.), Fruhschein der Kultur: Bilder aus Vorgeschichte und Urzeit, Mar. 5, Suppt., 2
Lévy-Bruhl (Prof. L.), translated by Lilian S. Clare, How Natives Think (Les Fonctions mentales dans les sociétés inférieures), 700
Luquet (G.-H.), L'Art et la religion des hommes fossiles, 8
Malinowski (Dr. B.), Crime and Custom in Savage Society, 633
Maori Symbolism: being an Account of the Origin, Migration, and Culture of the New Zealand Maori, as recorded in Certain Sacred Legends, Report made by Ettie A. Rout, from the Evidence of Hohepa Te Rake, 386
v. Merhart (G.), Bronzezeit am Jenissei: ein Beitrag zur Urgeschichte Sibiriens, 775
Moret (Prof. A.), and G. Davy, translated by V. Gordon Childe, From Tribe to Empire: Social Organisation among Primitives and in the Ancient East, 556
Norden (H.), Byways in the Tropic Seas: Wanderings among the Solomons and in the Malay Archipelago, 777
Rodd (F. Rennell), People of the Veil: being an Account of the Habits, Organisation, and History of the Wandering Tuareg Tribes which inhabit the Mountains of Aïr or Asben in the Central Sahara, 551
Rose (Prof. H. J.), Primitive Culture in Italy, Mar. 19, Suppt., 9
Sedgwick (Mrs. W. T.), Acoma, the Sky City: a Study in Pueblo-Indian History and Civilization, 44
Shetelig (Dr. H.), Préhistoire de la Norvège, Mar. 5, Suppt., 1
Shirokogoroff (S. M.), Anthropology of Eastern China and Kwangtung Province, 231
Smith (Rev. Frederick), Prehistoric Man and the Cambridge Gravels, 523
Summers (Dr. M.), The History of Witchcraft and Demonology, 882
Westermarck (Prof. E.), The Goodness of Gods, 557
Wheeler (G. C.), Mono-Alu Folklore (Bougainville Strait, Western Solomon Islands), 386
Wilder (Prof. H. H.), The Pedigree of the Human Race, Mar. 19, Suppt., 9.

Biology:

Allen (Grant), The Story of the Plants. New edition, Mar. 19, Suppt., 10
Allen (Dr. G. M.), Birds and their Attributes, Mar. 5, Suppt., 2
Ambronn (H.), und A. Frey, Das Polarisationsmikroskop, seine Anwendung in der Kolloidforschung und in der Farberei, Mar. 5, Suppt., 5
Bahl (Prof. K. N.), The Indian Zoological Memoirs on Indian Animal Types. 1: Pheretima (The Common Indian Earthworm), 557
Barclay (D.), H. M. L. Bolus, and E. J. Steer, A Book of South African Flowers, 557

Macpherson (Dr. H.), Modern Astronomy : its Rise and Progress, Mar. 19, Suppt., 13
de Montmorency (H.), From Kant to Einstein, Mar. 19, Suppt., 14
Moulton (Prof. F. R.), New Methods in Exterior Ballistics, 485
Müller-Pouillets Lehrbuch der Physik. Elfte Auflage. Herausgegeben von A. Eucken, O. Lummer, und E. Waetzmann. In fünf Bänden. Band 2 : Lehre von der strahlenden Energie (Optik). Erste Hälfte. Bearbeitet von O. Lummer. Band 3 : Wärmelehre. Erste Hälfte : Physikalische, chemische und technische Thermodynamik (einschl. Wärmeleitung). Bearbeitet von A. Eucken, Mar. 5, Suppt., 6
Optical Convention : The, 1926, Catalogue of Optical and General Scientific Instruments, 383 ; *Proceedings* of the, 1926. 2 Parts, 383
Parsons, William, The Scientific Papers of, Third Earl of Rosse, 1800–1867, collected and republished by the Hon. Sir Charles Parsons, 627
Physik, Handbuch der, Herausgegeben von H. Geiger und K. Scheel. Band 1 : Geschichte der Physik ; Vorlesungstechnik, K. Scheel, 189
Proctor (Mary), Legends of the Sun and Moon, Mar. 19, Suppt., 14 ; The Romance of Comets, Mar. 19, Suppt., 14
Rosse, Third Earl of, The Scientific Papers of William Parsons, 1800–1867, collected and republished by the Hon. Sir Charles Parsons, 627
Snow (A. J.), Matter and Gravity in Newton's Physical Philosophy : a Study in the Natural Philosophy of Newton's Time, 454
Sommerfeld (Prof. A.), Three Lectures on Atomic Physics. Translated by Dr. H. L. Brose, 488
Steffensen (Prof. J. F.), Interpolation, 921
Stoner (Dr. E. C.), Magnetism and Atomic Structure, 809
Taylor (Prof. L. W.), W. W. Watson, and Prof. C. E. Howe, General Physics for the Laboratory, Mar. 19, Suppt., 15
Véronnet (A.), Constitution et évolution de l'univers, 850

Medical Science :

Anatomy : Descriptive and Applied, H. Gray. Twenty-third edition, edited by Prof. R. Howden. Notes on Applied Anatomy revised by J. Clay and Dr. J. D. Lickley, 921
Austin (Prof. J. H.), and Prof. G. E. Cullen, Hydrogen Ion Concentration of the Blood in Health and Disease, 742
de Beer (G. R.), The Comparative Anatomy, Histology and Development of the Pituitary Body, 420
Bernhard (Dr. O), Light Treatment in Surgery, 701
Chandler (Dr. A. C.), Animal Parasites and Human Disease. Third edition, 885
Diet in relation to Health, The Importance of, 44
Evans (Prof. C. Lovatt), Recent Advances in Physiology. Second edition, 596
Gibson (Dr. A. G.), The Radcliffe Infirmary, Mar. 19, Suppt., 20
Kerr (Dr. J), The Fundamentals of School Health, 269
Kilduffe (Dr. R. A.), A Manual of Clinical Laboratory Procedure : for the Use of the General Practitioner, Mar. 19, Suppt., 17
Lake (R.), Contributions to the Art and Science of Otology. Lectures and Papers, 1892–1925, 233
McKenzie (T. C.), and A. A. King, Practical Ultra-Violet Light Therapy : a Handbook for the use of Medical Practitioners, 80
Medical Report of the Hamilton Rice Seventh Expedition to the Amazon, in conjunction with the Department of Tropical Medicine of Harvard University, 1924–1925, 885
Norton (Prof. J. F.), and Prof. I. S. Falk, Laboratory Outlines in Bacteriology and Immunology, Mar. 19, Suppt., 17
Sharpey-Schafer (Sir E.), The Endocrine Organs : an Introduction to the Study of Internal Secretion. Second edition. Part 2, 420

Metallurgy :

Friend (Dr. J. Newton), Iron in Antiquity, 42
Smithells (Dr. C. J.), Tungsten : a Treatise on its Metallurgy, Properties, and Applications, 884

Meteorology :

British Rainfall, 1925 : the Sixty-fifth Annual Volume of the British Rainfall Organization, 232
Defant (Prof. A.), Wetter und Wettervorhersage (Synoptische Meteorologie). Zweite Auflage, 843
Dorr (Dr. J. N.), Tafeln zur Bestimmung des Wasserdampfgehaltes der Luft mittelst eines Haarhygrometers und Thermometers gerechnet und erläutert. Anleitung zur Behandlung eines Haarhygrometers und zur Verwertung für die lokale Wettervorhersage, von Dr. A. Schlein, 116
McAdie (Prof. A.), Man and Weather, 274
Meteorology, Manual of, Vol. 1 : Meteorology in History, Sir Napier Shaw, with the assistance of Elaine Austin, 915
Observatories' Year Book, The, 1923 : comprising the Results obtained from Autographic Records and Eye Observations at Lerwick, Aberdeen, Eskdalemuir, Cahirciveen (Valencia Observatory), Richmond (Kew Observatory), and Benson, 663
Pick (W. H.), A Short Course in Elementary Meteorology. Second edition, 274

Miscellaneous :

Annual Register, The, A Review of Public Events at Home and Abroad for the Year 1926, edited by Dr. M. Epstein, 889
Belloc (H.), A Companion to Mr. Wells's "Outline of History," 75 ; Mr. Belloc still objects to Mr. Wells's "Outline of History," 75
Beresovski-Chestov (T.), Statistique intellectuelle de la France : tableaux relatifs à l'enseignement public, aux bibliothèques, aux spectacles, aux publications,

préparés sous les auspices de l'Institut International de Coopération Intellectuelle et de l'Institut de Statistique de l'Université de Paris. Année 1923–24, 345

Sonnenschein (W. Swan), The Best Books. Third edition. Part 4, 453
Subject Index to Periodicals, The, 1922. K: Science and Technology, 312
Universities of the Empire, The Yearbook of the, 1927, edited by W. H. Dawson, 888
Wells (H. G.), Mr. Belloc objects to "The Outline of History," 75
Whetham (C. Dampier), Politics and the Land, 845
Whitaker (J.), An Almanack for the Year of Our Lord 1927: containing an Account of the Astronomical and other Phenomena, and a Vast Amount of Information respecting the Government, Finances, Population, Commerce, and General Statistics of the various Nations of the World. Complete edition. Abridged edition, 80

Philosophy and Psychology:

Barrett (Sir William), and T. Besterman, The Divining Rod: an Experimental and Psychological Investigation, 310
Brown (Dr. W.), Mind and Personality: an Essay in Psychology and Philosophy, 630
Campbell (Prof. C. M.), Delusion and Belief, 487
Dunne (J. W.), An Experiment with Time, 847
Genetic Studies of Genius, edited by L. M. Terman. 2 Vols., 695
Miller (Dr. E.), Types of Mind and Body, 702
Parsons (Sir John Herbert), An Introduction to the Theory of Perception, 773
Smuts (Genl. the Rt. Hon. J. C.), Holism and Evolution, 307
Streeter (Rev. Canon Burnett Hillman), Reality: a New Correlation of Science and Religion, 273
Woodruff (D.), Plato's American Republic, 455

Technology:

American Annual of Photography, 1927, Vol. 41, edited by F. R. Fraprie and E. J. Wall, 80
Barnard (J. E.), and F. V. Welch, Practical Photo-Micrography. Second edition, 313
Blunt (H. S.), Gum Arabic: with special reference to its Production in the Sudan, Mar. 19, Suppt., 11
Bragg (Sir William), Old Trades and New Knowledge: Six Lectures delivered before a 'Juvenile Auditory' at the Royal Institution, Christmas 1925, 272
Christy (Miller), The Bryant and May Museum of Fire-making Appliances: Catalogue of the Exhibits, 777
Hall (A. J.), Textile Bleaching, Dyeing, Printing, and Finishing Machinery, 700
Penrose's Annual: the Process Year Book and Review of the Graphic Arts, edited by W. Gamble. Vol. 29, 1927, 274
Scales (Dr. F. S.), Practical Microscopy: an Introduction to Microscopical Methods. Third edition, 557
Searle (A. B.), Cement, Concrete, and Bricks. Second edition, 455

Rhodesia, The Stone Age in, Neville Jones, 226
Rhodesian Man, Restoration of the left innominate bone of, W. P. Pycraft, 836
Riemannian Geometry, Prof. L. P. Eisenhart, 117
Rime, A Remarkable Deposit of, F. J. W. Whipple, 328
River Pollution: and Fisheries, 1; and the Acidity of Natural Waters, W. J. M. Menzies, 638; Fundamental Problems relating to, H. W. Harvey, 463
Rivista di Fisica, Matematica and Scienze Naturali, 364
Rock: of Unknown Origin from Glacial Gravel at Ipswich, A. J. Reid Moir, 50; Paintings from the Central Sahara, Dr. P. Durand and L. Lavauden, 404; -faulting from the Engineering Standpoint, H. Briggs, 302
Rockefeller Foundation: Annual Report for 1925, Dr. G. E. Vincent, 576; Awards of Medical Fellowships, 908
Rocksalt, Refractive Index of, Effect of Temperature on the, Sir R. Robertson and Dr. J. J. Fox, 318
Roman Lead from Folkestone and Richboro' Castle, The Silver Contents of, Dr. J. Newton Friend and W. E. Thorneycroft, 585
Rontgen: Radiation of Seedlings, E. Berta, 222; Spectrography of Pearls, Study of the, J. Galibourg and F. Ryziger, 71
Rotation of Bodies with Dielectric Surfaces in Electrostatic Fields, G. L. Addenbrooke, 389
Rove Tunnel, The, 538
Royal: Academy: of Sciences of Amsterdam, Prof. F. G. Donnan elected a member of the, 902; The Exhibition of the, 1927, 714; Aeronautical Society, Prof. L. Prandtl awarded the gold medal of the, 724; Astronomical Society: Annual Report, 794; election of officers, 292; the gold medal of the, awarded to Prof. F. Schlesinger, 133; Cornwall Polytechnic Society, The, 503; Engineers, The Work of the, in the European War, 1914–1918. compiled by Col. G. H. Addison. Miscellaneous, 811; Geographical Society, awards of the, 504; Institution, election of officers, 681; Meteorological Society, Sir Gilbert Walker re-elected president, 169; Microscopical Society, election of officers, 292; Observatory, Greenwich, Annual Visitation, 873; retirement of Dr. A. C. D. Crommelin, 790; Photographic Society, the Progress medal of the, awarded to G. Eastman, 133; Scottish Museum, Exhibition of scientific research work in the Woollen and Worsted Industries, 935; Society Election, Selected candidates, 335, 755; Society of Edinburgh: award of the Makdougall-Brisbane prize to Dr. C. M. Wenyon, and of the James Scott prize to Sir Joseph Larmor; 902; creation of a Publications Fund, 934; election of fellows, 470
Rubber: Electro-deposition of: 129; Dr. S. E. Sheppard, 393; Yield, Inheritance of, R. A. Taylor, 683
Rugosa Corals described by W. Lonsdale in Murchison's "Silurian System," A Critical Revision of the, W. D. Lang and S. Smith, 545

Runge, Prof. Carl, Sir Oliver Lodge, 565
Russia: Agricultural Map of, Prof. I. F. Makarov, 138; Mineral Deposits in, 368
Russian: Academy of Sciences, Prof. A. Einstein, Mme. Curie, Prof. W. Nernst, Prof. A. A. Michelson, and Prof. M. G. Mittag-Leffler elected honorary members of the, 793; Exploration in Mongolia, 333; Lapland, The Tundra Vegetation of, Prof. R. R. Gates, 301; North, Exploration of the, 175; Work on Microbiology, 175

Saccharin, A Study of the Determination of, A. F. Lerrigo and A. L. Williams, 546
Saccharose, The Law of Hydrolysis of, by Acids, H. Colin and Mlle. A. Chaudin, 182
Safety-in-Mines Research Board, The New Experimental Station of the, opening of, 942
St. Andrews University: bequest by W. Gibson to University College, Dundee, 103; gifts to, 476; Dr. G. J. Robertson appointed lecturer in chemistry in the United College, 656, 688; Prof. H. J. Rose appointed to the chair of Greek in the United College, 835
Salmon: of the River Grand Cascapedea, Canada, W. L. Calderwood, 513; Spey, W. J. M. Menzies, 830
Salopian Rocks and Tectonics of the District South-west of Ruthin, The, Prof. P. G. H. Boswell, 878
Salt in the Air, Rain, and Rivers of this Country, The Presence and Distribution of, W. Irwin, 446
Saltern Cove Area (Torbay), The Geology of the, L. G. Anniss, 545
Sampling, A Convenient and Rapid Method of, C. E. R. Bruce and W. B. Whitney, 892
San Andreas Rift, The, Dr. L. F. Noble, 834
Sand-flies and Chinese Kala-azar: E. Hindle and Major W. S. Patton, 460; Major H. E. Short, 893
Sanguinicola, Studies on, Dr. L. Ejsmont, 580
Santalaceæ, The Geographical Distribution of some, T. A. Sprague and V. S. Summerhayes, 945
Sarawak, The Peoples of, Dr. A. C. Haddon, 806
Savignano Statuette, The, R. Vaufrey, 438
Scattering, Classical, The Limits of, P. M. S. Blackett, 657
Schilluk: Die, Geschichte, Religion und Leben eines Niloten-Stammes. Nach P. Banholzers F.S.C. und eigenen Aufzeichnungen dargestellt, Father W. Hofmayr, 113
Scholes Bomb Calorimeter, The, G. Cussons, Ltd., 296
School Health, The Fundamentals of, Dr. J. Kerr, 269
Schools and Universities, 109
Schrödinger's Quantum Theory, P. S. Epstein, 838
Schroter, Carl, Festschrift, Prof. R. H. Yapp, 153
Sciara (Diptera), Genetic Evidence of a Selective Segregation of Chromosomes in, C. W. Metz, 388
Science: and Food Production, Sir E. J. Russell; The Reviewer, 636; and Human Life, 449; and Preconceived Perfection, Prof. D. Fraser Harris, 330; and Psychic Behaviour, Prof. H. Levy, 484; and the Humanities, 454; and Wonderland, E. Edser, 435; Current, Some Comments on, Sir Oliver Lodge, 387; Forthcoming Books of, 441; in Great Britain, A Representative Body for, 341; in Japan, Prof. C. C. Farr, 407; Masters' Association, The, annual meeting of the, 102; Museum, South Kensington: addition to the, of part of the *Turbinia*, 935; Catalogue of the Collections in the, 613; Catalogue of the Electrical Engineering Section, 900; Exhibition of the Application of Science to the Wool Industry, 330; Popular, Essays in, Prof. J. S. Huxley, 848; The Anatomy of, Prof. G. N. Lewis, 228
Sciences in Greco-Roman Antiquity, History of the, Prof. A. Reymond, translated by Ruth Gheury de Bray, 776
Scientific: Achievement and Aptitude, Prof. T. D. A. Cockerell, 84; and Industrial Research: 617; Committee of the Privy Council for, H. T. Tizard appointed Secretary to the, 504, 610; Sir Richard Glazebrook appointed a member of the, 866; and Learned Societies of Great Britain and Ireland, The Year-Book of the, Forty-third Annual Issue, 522; and Technical Books, Recent: Jan. 29, Suppt., v; Feb. 26, Suppt., v; April 2, Suppt., v; April 30, Suppt., v; May 28, Suppt., vii; June 25, Suppt., v; Books, Prices charged for, Prof. R. Pearl, 577; Discovery, An Amusing Conception of, X. Y., 14; Travellers, Practical Hints to, edited by Prof. H. A. Brouwer, Vol. 4, 455
Scoria, The Granulation of, B. Bogitch, 183
Scott, John, medal, award of the, to G. W. Elmen, 24
Scottish: Salmon, J. M. Menzies and P. R. C. Macfarlane, 438; Sea Trout, G. H. Nall, 404
Sea: Anemones, Fluorescence of, Major C. E. S. Phillips, 747; -level, Recent Lowering of, A. F. Buddington, 254; The Thermal Energy of the, The Utilisation of, G. Claude and P. Boucherot, 70; Water: Evaporation of, Measurement of, Prof. W. Shoulejkin, 891; The Transparency of, for the Extreme Ultra-violet, K. Tsukamoto, 373
Secondary Electronic Emission, The Application of the Method of the Magnetic Spectrum to the Study of, C. F. Sharman, 34
Secretion, The Problem of: Dr. R. H. Bowen, 30; Prof. J. P. Hill and Dr. J. A. Murray, 163
Semipinacolic Transposition, The Reality of the, M. Tiffeneau and Mlle. J. Lévy, 146
Separation and Pasteurisation, Influence of, on the Size and Distribution of, Fat Globules in Milk and Cream, Dorothy Beckett, 658
Serpentines of the Shetland Islands, The, and the Associated Rocks and Minerals, F. C. Phillips, 836
Serum, and the Blood Globules of the Horse, The Comparative Compressibility of the, M. Fontaine, 587
Sewri, The Caves of, J. Ribeiro, 374
Sex: -change in the European Oyster, Researches on, Dr. J. H. Orton, 177; -transformation, A Case of Partial, in Cattle, A. Calder, 946
Sexes in Plants, Biochemical Differences between, Sophia Satina and A. F. Blakeslee, 838
Sextic Equation, A 15-ic Resolvent of the, J. Lamb, 338
Shark, Nematode Eggs from Skin and Gills of, G. A. MacCallum, 367
Sharpey-Schafer (Sir E.), The Endocrine Organs: an Introduction to the Study of Internal Secretion. Second edition, Part II., 420
Sheep, The Coat of: Prof. J. E. Duerden, 815; Prof. J. Cossar Ewart, 426
Shelley Memorial Trust, A, 400
Shilluk Begging Customs, Rev. D. S. Oyler, 651
Shipbuilding and the Shipbuilding Industry, J. Mitchell, Mar. 19, Suppt., 20
Ships, Ancient, G. S. Laird-Clowes, 253
Shock-Wave following Detonation of High Explosives, The, W. Payman and W. C. F. Shepherd, 27
Shot-hole Borer of Tea, The, F. P. Jepson and C. H. Gadd, 760
Siberia: Prehistoric Cultures of, 367; The Geology of, 309; Zoological Exploration in, 439
Siberian Bronze Age Cultures, M. C. Burkitt, 775
Siberien, Geologie von, Prof. W. A. Obrutschew (Fortschritte der Geologie und Palaeontologie. Herausgegeben von Prof. W. Soergel, Heft 15), 309
Sierra Leone: A View of, F. W. H. Migeod, 849; its History and Tradition, Capt. F. W. Butt-Thompson, 849
Silica Valves, H. Morris-Airey, G. Shearing, and H. G. Hughes, 757
Silicates: certain, The Structure of, Prof. W. L. Bragg and J. West, 412, 477; Researches on the, E. Cherbuliez and P. Rosenberg, 587
Silicic Acid Gel, Behaviour of, during the Drying-up Process, Dr. J. B. Firth and H. A. Fells, 84
Silurian: Echinoidea Echinocystis and Palaeodiscus, The Occurrence, Morphology, and Affinities of the, H. L. Hawkins and Miss S. M. Hampton, 689; Jelly Fish, A, F. Chapman, 514
Silver: The Atomic Weight of: Prof. H. B. Baker and H. L. Riley, 348, 703; Prof. H. Brauner, 348, 526
Simulium Larva, The Mechanism of the so-called 'Posterior Sucker' of a, Dr. Sunder Lal Hora, 599
Singapore Botanic Gardens, Guide to the, 648

Skeletogenous Strata, Some Aspects of the Morphology and Ontogeny of the, Prof. C. G. S. de Villiers, 67
Skilled Performances, Recent Studies of, with Reference to the Transfer of Training, Prof. T. H. Pear, 906
Skua, Great, Protection of the, 174
Skulls of Early Tertiary Suidæ, etc., On the, H. Pearson, 877
Slaughtering: of Animals, Humane, Discussion on, 402; Scientific, Capt. C. W. Hume, 481
Sliding Surfaces, 'Seizure' with, J. M. Macaulay, 425
Small Holdings and Forestry, Lord Clinton, 175
Smaller (Technical) Institution, Some Problems of the, Principal J. F. S. Ross, 411
Smithsonian Institution: gift to, by F. Canu, of fossil invertebrates, 291; Report of the, 505; the botanical library of Capt. J. D. Smith deposited in the, 250
Smut Fungi: The Physiology and Genetics of the, Hyphal Fusion, S. Dickinson, 220
Snowdon Massif, The Geology of the, H. Williams, 33
Soap and Detergent Industry, The Modern, including Glycerol Manufacture, Dr. G. Martin. In 3 vols. Vol. 3, 79
Social Progress and Educational Waste: being a Study of the 'Free-Place' and Scholarship System, K. Lindsay, 810
Sociologie: Éléments de, textes choisis et ordonnés, Prof. C. Bouglé et J. Raffault, Mar. 5, Suppt., 1
Soda-lead Oxide Glasses, Properties of some, Violet Dimbleby, S. English, Prof. W. E. S. Turner, and F. Winks, 621
Sodium: Chloride, Heat of Solution of, S. G. Lipsett, 832; in Plants, The Presence of, G. Bertrand and J. Perietzeanu, 621
Soil Characteristics: a Field and Laboratory Guide, Prof. P. Emerson, 596
Soils, The Soluble Silicate Content of, Dr. W. R. G. Atkins, 803
Solar: Corona, The Forms of the, and their Origin, Dr. W. J. S. Lockyer, June 18, Suppt., 93; Eclipse: of June 29: Suggested Observations of Terrestrial Magnetism and Atmospheric Electricity, 95; Ordnance Survey Map of the, 437; The Coming, 682; Total, of May 9, 1929, Z. A. Merfield, 514; Eclipses, Total, in the British Isles, Dr. W. J. S. Lockyer, 87; Physics Observatory, Cambridge, Report of the, 25; Radiation: Dr. C. G. Abbot, 212; R. Segiguti, 366; and Athermancy, A. F. Dufton, 14; and Diathermancy, A. F. Dufton, 460; in the Lyman Region, Z. A. Merfield, 514
Solid Fuels, Ignition Temperatures of, K. Nakamura and A. Shimomura, 215
Solute in Liquid Mixtures, The Solution Volume of a, G. J. Burrows, 222
Solutions of the Strong Acids, Nature of, from the Standpoint of the Salt Effect, H. M. Dawson and L. H. Angus, 35
Somaliland, Jurassic and Eocene Echinoidea from, Ethel D. Currie, 946
Sörensen Equation for the Isoelectric Points of Ampholytes, Development of the, W. R. Atkin, 338
Sound: -absorption, Measuring, at Normal Incidence, On the Stationary-wave Method of, Dr. E. T. Paris, 657; in Wide Pipes, Propagation of, T. Vautier, 406
South: Africa: Archæology in, H. Balfour, 226; Mining and other Industries in, Science in Relation to, Dr. E. T. Mellor, 67; Palæontology in, Dr. S. H. Haughton, 652; Poisonous Plants of, 580; The Geology of, Dr. A. L. Du Toit; Prof. J. W. Gregory, 665; Union of, The Chemical Service of the, Dr. St. C. O. Sinclair, 67; African: Association: The Pretoria meeting of the, 67; Prof. H. B. Fantham elected president of the, 68; Flowers, A Book of, D. Barclay, H. M. L. Bolus, and E. J. Steer, 557; Native Policy, The Need of a Scientific Basis for, J. D. R. Jones, 67; Thunderstorms, The Electric Fields of, B. F. J. Schonland and J. Craib, 260; American Indians: The Civilization of the, with special reference to Magic and Religion, Prof. R. Karsten, 921; Australian Aborigines of. Anthropometry of the, Dr. T. D. Campbell and Dr. A. J. Lewis, 138; Coal in, 214; -eastern Union of Scientific Societies, Annual Congress, 874; -west England, A Regional Survey of, 901
Southern Kor Alps of Styria, Geological Petrographic Researches in the, A. Kieslinger, 587
Spahlinger's Treatment, After Results of, Dr. T. Nelson, 171
Species, Fluctuations in the Abundance of a, considered mathematically, Dr. A. J. Lotka; Prof. V. Volterra, 11
Specific Heats of a Sufficiently Cooled Non-condensed Phase, The, N. Perrakis, 262
Spectroheliöscope, The, and Direct Telescopic View of Solar Prominences, A. A. Buss, 780
Spectroscopic Parallaxes, Adams, Joy, and Humason; A. V. Douglas, 331
Spectrum Lines, Intensity of, On Measurement of, T. R. Merton, 181
Speech and Music, Frequencies employed in, 440
Spencer's, Herbert, Electrical Apparatus, F. W. Shurlock, 672
Spermatogenesis in the Mouse and the Rabbit, K. Masui, 26
Sphæropsis Malorum, Variation in, K. R. Mohendra, 657
Spider, Poisoning by a, 649
Spiders, Courtship in, W. S. Bristowe and G. H. Locket, 294
Spiers Memorial Fund, The, 827
Spinning: Electron: and Wave Mechanics, E. Guth, 744; The, in Wave Mechanics, Prof. A. Carrelli, 492; Electrons, R. H. Fowler, 90
de Spinoza: Benedictus, Prof. G. Dawes Hicks, 357; The Philosophy of, Some Aspects of, A. Wolf, 545
Spitsbergen, The Nature and Origin of, Soil-polygons in, C. S. Elton, 181
Spleen, A Mycosis of the, in Algeria, The Frequent Existence of, P. E. Pinoy and A. Nanta, 446
Staining Sections in Acetone, A Method of, A. Kefalas, 260
Standards, Bureau of, Washington, Report of the, 648
Star: Catalogue, A New Photographic, 98; The Interior of a, Prof. S. Rosseland, 111
Stars: Distribution of, Some Systematic Features in the, F. H. Seares, 461; Faint, Proper Motions of, Dr. W. M. Smart; Dr. H. Knox Shaw, 471; Southern Double, W. H. van den Bos, 505; The Internal Constitution of the, Prof. A. S. Eddington, 111; The Number of the, Dr. C. G. Abbot, 903; The Scintillation of the: G. Rossi, 414; at the Royal (Italian) Observatory, Campidoglio, G. Rossi, 691; The Survey of the, Dr. J. H. Jeans, 394
Starch: Grains in Plant Cells, Various Modes of Digestion of, A. Maige, 478; on the Tables of Starch Factories, The Deposit of, P. Nottin, 514; The Hydrolysis of, by Sulphuric Acid, P. Nottin, 947
State, The, and Industrial Research, 589
Statesman's Year Book: The, 1927, edited by Dr. M. Epstein, 889
Steam-engine, The, and other Heat-engines, Sir J. Alfred Ewing. Fourth edition, 633
Steel: at Low Temperatures, Impact Tests of, R. Yamada, 215; The Penetration of Mild, by brazing Solder and other Metals, R. Genders, 584
Steers: The Basal Metabolism of, Dr. F. G. Benedict and E. G. Ritzman, 839; The Metabolic Stimulus of Food in the Case of, Dr. F. G. Benedict and E. G. Ritzman, 839
Stellar: Absorption Lines, The Distribution of Intensity in, Miss Payne and Dr. Shapley, 98; Parallaxes, etc., Dr. J. H. Jeans, 287
Stimuli in Plants, Transmission of, Prof. Nigel G. Ball, 638
Stone, The Preservation of, S. Russell, 832
Storia della Scienza, Archivio di, made more international, 827
Strasbourg University, an honorary professorship conferred on Prof. G. H. F. Nuttall, 612
'Streaks' (*Schlieren*) in Chemical Experiments, F. Emich, 659
Strokes in Writing, The Sequence of, C. Ainsworth Mitchell and T. J. Ward, 689
Subject Index to Periodicals, The, 1922. K: Science and Technology, 312

Submarine Cable, Second, connecting Canada with Australasia, E. S. Heurtly, 538

Submergence, Local Coast, Prof. D. W. Johnson and W. E. Pratt, 175

Sugar: Beet: 869; in England, G. T. Brown, 795; -cane Root Disease, Mollusc as agent in the, Dr. P. Bartsch and Mary E. Quick, 295

Sugars, Rotatory Power and Structure of, C. S. Hudson, 616

Sulphide Waters, the Decomposition of, The Influence of the Ionic Reaction on, A. Desgrez, L. Lescœur, and Mlle. S. Manjean, 182

Sulpho-salts, Investigations on (ii.), L. Fernandes and F. Palazzo, 803

Sulphur: Dioxide: Additive Products of, with Aromatic Hydrocarbons, Note II., F. De Carli, 374; and Aromatic Hydrocarbons, Additive Compounds of, F. De Carli, 222; Lengthened Chain Compounds of, Sir P. C. Rây, 124; Trioxide, Forms of, G. Oddo and A. Casalino, 508

Sumerian Tablets, 99

Sun: Circles in Ritual Dances, W. E. F. Macmillan, 14; and Moon, Legends of the, Mary Proctor, Mar. 19, Suppt., 14; Horizontal Diameter of the, in 1925 and 1926, G. Armellini, 690; the Atmosphere of the, The Fields of Force in, Dr. G. E. Hale, 708; The, the Earth's Atmosphere, and Radio Transmission, Prof. S. Chapman, 428

Sun's Motion derived from Faint Stars, The, P. van de Kamp, 366

Sunspot: Activity: 1926–27, 64; Activity, Recent, 759; A Large, 173, 903; and Magnetic Disturbance, Recent, 98; Frequencies and Terrestrial Phenomena, Prof. T. Terada, 293

Suprarenal Capsules in Water, Fatty Acids, and Cholesterol in the Normal Guinea-pig, etc., Comparative Variations in the Content of the, L. Randoin and Mlle. A. Michaux, 106

Surface: Adsorption and the Velocity of Chemical Action at Gas Solid Interfaces, Dr. F. H. Constable, 445; Phenomena, W. Ramsden, 802; Tension: of Insulating Liquids submitted to the Electric Field, The, G. Bruhat and M. Pauthenier, 182; of Liquid Mixtures in the Neighbourhood of the Critical State, The, P. Brun, 837; The Variation of, with Temperature, J. E. Verschaffelt, 414; Waves due to Small Artificial Disturbances of the Ground, E. H. Booth, 303

Surfaces, The Polishing of, Prof. J. Muir; N. K. Adam, 279

Suspensions, The Stability of (ii.), W. O. Kermack and W. T. H. Williamson, 946

Swan, Submergence and Postural Apnœa in the, Prof. D. Noel Paton, 803

Swansea University College, Prof. C. A. Edwards appointed principal of, 765

Swiss Society of Natural Sciences, forthcoming annual meeting, 866

Sydney University: Dr. P. G. Carter appointed lecturer in organic chemistry in, 656; The Botany School of the, 500

Symons Memorial Lecture, Prof. G. I. Taylor, 586

Synchronous Alternating-current Motors and Mechanical Vibrating Systems, etc., T. G. Hodgkinson, 338

Syphilis, The Treatment of, Prof. E. E. Glynn, Dr. R. E. Roberts, and Mrs. Bigland, 65

Tabulæ Biologicæ, Ed. W. Junk, Herausgegeben von C. Oppenheimer und L. Pincussen. Band 3, Mar. 5, Suppt., 8

Tadpoles and Fry, Photo-reactive Behaviour in, Fed with Thyroid, E. Remotti, 107

Tahitian Coral Reefs, Recession of the, Dr. C. Crossland, 597

Talysh, The Flora of the, A. A. Grossheim, 213

Tank Testing, The Value of, G. S. Baker, 296

Tantalum, Niobium, The Analytical Chemistry of, and their Mineral Associates, W. R. Schoeller and C. Jahn, 836

Tar-distillate Sprays, 175

Tartaric Acid: containing Boric Acid, The Anomalous Rotatory Dispersion in the Ultra-violet of three Aqueous Solutions of, R. Descamps, 513; The Rotary Power of, L. Longchambon, 71

Technical: Education: and Industry, 517; The Value of, H. Hall, 876; Institutions, Association of, Annual General Meeting, 411

Tectonics and Petrogenesis, Prof. W. N. Benson, 761

Teleostean Fishes, The Homologues of the Adrenal or Suprarenal Bodies in, Prof. Swale Vincent and F. R. Curtis, 83

Telephone, The History and Development of the, Sir Oliver Lodge, 244

Telescope: A New Reflecting, for Edinburgh, 173; the Magnification of a, An Empirical Rule concerning, M. Hamy, 946

Telescopic Images, Stability of, The Interferential Study of Scintillation and the Conditions of, A. Danjon, 106

Television: J. L. Baird, 73, 101, 161, 865; Dr. A. Russell, 198; Prof. E. Taylor Jones, 896; in America, 647; (Seeing by Wire or Wireless), A. Dinsdale, 887

Tell el-Amarna, Excavations at, H. Frankfort, 574

Temperature, Some Measurements of, near the Surface in Various Kinds of Soil, N. K. Johnson and E. L. Davies, 145

Temple of Madamud near Luxor, Archæological Discoveries at the, F. Bisson de la Roque, 825

Tennessee, Upper Cretaceous Fossils of, B. Wade, 615

Teredo: Formation of Calcareous Tubes round the Siphons of, Dr. C. M. Yonge, 11; The Giant, Dr. W. T. Calman, 104

Termites (Isoptera) from South Sea and Torres Strait Islands, G. F. Hill, 514

Terrestrial Magnetism: Section of, of the International Union for Geodesy and Geophysics, Preliminary Report on Subjects of Investigation, 292; Wireless Communication and, Dr. C. Chree, 82

Tetanus Toxin, Velocity of Flocculation and Velocity of Neutralisation of the Antitetanus Serum towards the, S. Schmidt, 910

Texas, Two Shallow Oilfields in, Dr. A. Wade, 684

Textile Bleaching, Dyeing, Printing, and Finishing Machinery, A. J. Hall, 700

Theodolite, An Ancient, 652

Thermal Energy of the Sea, The Utilisation of the, G. Claude, 106

Thermionic: Phenomena in a Magnetic Field, The, R. Moens and H. Steffens, 414; Rectifiers, The Characteristics of, C. L. Fortescue, 836; Valves, The Saturation Current of, A. Lo Surdo, 803

Thermodynamics, The New, 43

"These Hundred Years," Sir Gregory Foster, 300

Thorium-X, Influence of, on Laccase, A. Maubert, 653

Thrust Experienced by a Cylinder of any Section in a Current of Inviscid Liquid, J. L. Synge, 658

Thundercloud, Processes in a, Prof. C. T. R. Wilson, 502

Thunderstorm, The Mechanism of a, Dr. G. C. Simpson, 337

Thyroxine, Designation of, Prof. A. T. Cameron, 925

Tiber Shad, Growth of the, U. D'Ancona, 691

Tibet, A Crystal Mark from, H. C. Beasley, 174

Ticks, Micro-organisms in, Dr. E. V. Cowdry, 507

Tierwelt der Nord- und Ostsee, Die, Herausgegeben von G. Grimpe und E. Wagler. Lief. 5. Teil 9.d_1 und 12.a_1, Mar. 5, Suppt., 3

Time: An Experiment with, J. W. Dunne, 843; and Perception, Prof. H. Levy, 847; Measurement in an Isotropic Space-frame, J. L. Synge, 658

Tomb of the Third Dynasty found at Saqqara, C. Firth, 536

Torpedo Boats and their Machinery, Sir John E. Thornycroft, 537

Torsion-dynamometer, A New Recording, R. G. Parker and D. N. Jackman, 23

Tortoiseshell Cats, Mrs. Bisbee and Miss Catherine Herdman, 795

Tortugas, Biological Studies at the, 868

Tourmaline, Rutile, Brookite, and Anatase in the Dartmoor Granite, The Temperature-range of Formation for, A. Brammall and H. F. Harwood, 260

Toxicity, The Error of Determination of, J. W. Trevan, 878

Trans-Atlantic Telephone Service to Towns outside London and American States, 172

Transmutation: by Electronic Bombardment, Experiments to Test the Possibility of, M. W. Garrett, 260; of Elements, Some Geological Applications of, L. de Launay, 221
Transmutations in Geology, The Possible Rôle of, L. de Launay, 182
Transparent Microscopic Spheres, Double-image Effect in, H. S. Patterson and Prof. R. Whytlaw-Gray, 199
Trees, The New Book of, M. Woodward, 742
Trematodes, Anatomy of, A Simple Method of Demonstrating the, Ruth C. Bamber (Mrs. Bisbee), 766
Trevithick and Rastrick and the Single Acting Expansive Engine, A. Titley, 208
Tribal Dancing and Social Development, W. D. Hambly, 488
Tribe to Empire: From, Social Organisation among Primitives and in the Ancient East, Prof. A. Moret and G. Davy, translated by V. Gordon Childe, 556
Triewald, Martin, The Work of, A. Waerland, 23
Trifluoracetylacetic Acid and Ester, etc., F. Swarts, 910
Triplets in Multiple Births, The Occurrence of, Sir George Knibbs, 303
Tropic Seas: Byways of the, Wanderings among the Solomons and in the Malay Archipelago, H. Norden, 777
Tropical Cyclones of the Pacific, E. V. Newnham, 218
Trusts and National Progress, 149
Truth or Convenience, Sir Oliver Lodge, 423
Trypanosomiases, The Prophylaxy of the, by Ingestion of Moranyl (309 Fourneau or 205 Bayer), C. Levaditi and A. Klarenbeek, 947
Tuareg Tribes, Ethnology of, Prof. E. Westermarck, 551
Tungsten: a Treatise on its Metallurgy, Properties, and Applications, Dr. C. J. Smithells; Dr. O. Rosenhain, 884; Clean, A Comparison of the Thermionic and Photoelectric Work Functions for, A. H. Warner, 731
Tuning-forks: Electrically Driven, Distortion of Resonance Curves of, E. Mallett, 878; with Parallel Prongs: R. S. Maxwell, 124; Dr. G. E. Allan, 281
Turbulence, Prof. G. I. Taylor (Symons Memorial Lecture), 586
Tyndall's Experiments on Magne-crystallic Action, Sir William Bragg, 170; May 7, Suppt., 61

Ultramicroscopic Organisms as Symbionts, Prof. U. Pierantoni, 332
Ultra-violet: Light Therapy: Practical, a Handbook for the Use of Medical Practitioners, T. C. McKenzie and A. A. King, 80; Therapy Apparatus, Watson and Sons (Electro-Medical) Ltd., 406
Umbria: Descrizione geologica dell', Dr. B. Lotti, 475; The Hydrography and Geology of, Dr. C. Du Riche Preller, 475
Underground Railways of London, The Electrical Equipment of the Track on the, A. R. Cooper, [illegible]5
l'Univers, Constitution et évolution de, A. Véronnet, 850
Universities: and University Colleges of Great Britain and Ireland, Students from other Countries in the, 511; of the Empire, The Yearbook of the, 1927, edited by W. H. Dawson, 888; Schools and, 109
University: *Bulletin*, April, 765; Centre in London, A, 764; College, London, The Hundredth Anniversary of, 688; College of the South-west of England, Laying of a Foundation-stone by the Prince of Wales, 944; Government with Special Reference to the University of London, T. Ll. Humberstone, 444; Grants Committee, Returns from Universities and University Colleges in Receipt of Treasury Grant, 1925–1926, 733; Lecturers, Salaries of, Prof. J. Read, 528; Statistics and Tendencies, 733; Women, International Federation of, Report of Conference at Amsterdam, 179
Upper: Air, Thermodynamic Diagrams in the Study of the, Sir Napier Shaw, 118; Chalk, The Microscopic Characters of Certain Horizons of the, I. S. Double, 766
Ur, Excavations at, C. L. Woolley, 611
Ural Region, Impending Expedition to the, 436
U.S.A.: Accredited Colleges and Universities in the, 103; Bureau of Standards, Hon. H. Hoover and others, 134; Coast and Geodetic Survey in the, 439; Geophysics in the, 941; Insect Control in the, Dr. L. O. Howard, 473; Magnetic Elements in the, 542; National Academy of Sciences, election of officers and members, 86[illegible]; National Advisory Committee for Aeronautics, Dr. J. S. Ames elected chairman of the, 900; National Museum, New Species of Mollusca in the, the late Dr. Dall, 869; National Research Council, election of officers, 937; Statistics of Universities, etc., in the, 69; The Anti-evolution Movement in the, 863
Uterus, The Peripheral Innervation of the, Amy M. Fleming, 946

Vacation Courses in England and Wales, 1927, 800
Vacuum: Flask, Early Suggestion as to the, R. Inwards, 893; Technique, Mrs. M. A. Shirmann, 66; Tube, Large, 685
Valerolactones, *a* substituted, A Method of Preparation of, G. Darzens, 146
Valve Steels, P. B. Henshaw, 616
Vanadium and Tungsten, The Separation of, S. G. Clarke, 836
Vanoise and of Mont-Pourri (Savoy Alps) is Permian or Carboniferous, That the Crystallophyllian Series of the, P. Termier, 621
Vapour Pressures of Aqueous Solutions, A New Method of Determining the, Prof. R. Whytlaw-Gray and H. Whitaker, 35
Vapours, A New Pressure-temperature Formula for, Prof. A. Batschinski, 198
Varanus komodensis, the 'Dragon' of Komodo Island, Dutch East Indies, 436
Vegetable Chemistry, Comparative (xv.), J. Zellner and others, 35
Velocity of Catalytic Gas Reactions in Closed Vessels, The Effect of the Addition of Successive Small Quantities of Poisonous Substances on the, Dr. F. H. Constable, 945
Vertebrate Gut, Nomenclature of the, G. L. Purser, 855
"Vestigia, or The Year's Archæology in Pictures," 757
Vesuvian Sublimates, New Researches on Noteworthy, G. Carobbi, 107
Victoria, Some Early Palæozoic Plants from, Prof. W. H. Lang and Isabel C. Cookson, 261
Vigorous Exercise of Short Duration, Recovery from, R. M. Sargent, 144
Virgin Islands, Physiography of the, H. A. Meyerhoff and J. F. Kemp, 214
Viruses, Filterable, The Morphology of, J. E. Barnard, J. Smiles, and F. V. Welch, 583
Vitality of Young Animals, E. L. W. Heck, 760
Vitamin Assay, The Technique of, 216
Vitamins, Fat-soluble, 787
Vitrified Fort, A, at Dunagoil, Buteshire, L. M'Lellan Mann, 213
Vocational Guidance and Selection, Dr. C. S. Myers, 62
Volcanic Rocks of Central America, P. C. Putnam, 333
Volta, Centenary of the Death of, 362
Voltaic Cell, The Electronic Theory of the, O. M. Corbino, 622
Vredefort and Arran, Granite Domes of, E. B. Bailey, 214

Wales, The National Museum of, 642
Wallis's Axiom of Parallels, Prof. M. J. M. Hill, 727
Walrus, The, Dr. R. W. Gray, 923
Warble-fly in Denmark, The, H. Faber, 174
Water: -alcohol Mixtures, The Surface Tensions of, P. Brun, 622; and Industrial Development, W. D. Collins, 796; -borne Diseases, Remaining Possibilities of, 769; -finding Apparatus, Official Tests in India of, 469; -mills, Early, in relation to Changes in the Rainfall of East Kent, G. M. Meyer, 837; Vapour: in Compressed Gases, Concentration of, E. P. Bartlett, 440; in the Atmosphere, Dr. Kohler; Lieut.-Col. E. Gold, 654; The Band Spectrum of, D. Jack, 801
Watson's Microscope Record, No. [illegible]0, 331

Wattle Barks, Notes on. Part II., F. A. Coombs, W. McGlynn, and M. B. Welch, 303

Wave: Mechanics: and Classical Mechanics and Electrodynamics, Prof. G. A. Schott, 820; and the Rotation of Homopolar Molecules, D. M. Dennison, 316; The Symmetrical Top in, Prof. P. Debye and C. Manneback, 83; Propagation in Strings with Continuous and Concentrated Loads, Dr. H. Jeffreys, 945

Weather: and Weather Forecasting, Lieut.-Col. E. Gold, 843; Forecasts, Long-range: 60; Popular: Capt. C. J. P. Cave, 52, 167; Hon. Capt. R. P. Butler, 164; in November, The, 24

Wellcome: Bureau of Scientific Research, etc., The, 24; Historical Medical Museum, The, 833

West: Indian Stone Collars, A. D. Russell, 26; of Scotland Agricultural College Annual Report, 1925–26, 258

Wetter und Wettervorhersage (Synoptische Meteorologie), Prof. A. Defant. Zweite Auflage, 843

Whales: and Dolphins, 687; The Sleep of, Dr. R. W. Gray, 636

Whaling Industry, Radio in the, 255

'Wheat: a Quarter of,' Meaning of, Prof. R. A. Gortner and H. J. Page, 210; in 3500 B.C., Prof. J. Percival, 280; Species, The Genetics of, Prof. R. R. Gates, 370

Whither?—a Footnote, C. S. S., 205

Whitworth Book, The, Honorary Editor, Prof. D. A. Low, 776

Wild: Birds Protection Bill, The, 501; -fowl of Europe, The Present Status of the, Dr. P. R. Lowe, 209; The Way of the, H. R. Sass, 633

Wind: Drift, 443; Variation of, with Height at Melbourne when Geotropic Winds are northerly, H. M. Treloar, 838

Winter Thunderstorms in the British Islands: S. M. Bower, 123, 837

Wireless: Communication and Terrestrial Magnetism: Dr. C. Chree, 82; Dr. W. H. Eccles, 157; Pictures and Television: a Practical Description of the Telegraphy of Pictures, Photographs, and Visual Images, T. Thorne Baker, 887; Technique, The New, 155; Transmission and the Upper Atmosphere, Dr. E. V. Appleton, 679; Waves, Propagation of, Effect of a Large Number of Receiving Aerials on the, R. H. Barfield, 195

Witchcraft: An Orthodox View of, 882; and Demonology, The History of, Dr. M. Summers, 882

olfer's Sunspot Numbers considered as a Disturbed Periodic Series, G. U. Yule, 337

men: employed in Industry, The Physique of, Prof. E. P. Cathcart, 299; in Factories, 299

od: Old, The Characterisation of, as compared with Green Wood, R. Lyon, G. Fron, and M. Fournier, 658; Pulp from Poplar, 869

d, Trueman, Lecture, The, Dr. R. J. Tillyard, 202

's Light, The Method of applying, in Investigations n Vegetable Pathology, L. Petri, 479

oreeding Council, Appointment of a, 95

pe, The Silurian Inlier of, C. I. Gardiner and . C. Reed, 585

mole-Plot Memorial Windows at Oxford, The, 798

Xenopus, Pipa and Hymenochirus, The Comparative Anatomy of the Breast-shoulder Apparatus of the Three Aglossal Anuran Genera, C. G. S. de Villiers, 838

X-ray: Diffraction in Liquids, Prof. C. V. Raman and C. M. Sogani, 601; Spectra: of the Fatty Acids and their Mixtures, The Analytical Interpretation of the, J. J. Trillat, 690; of the Normal Saturated Dicarboxylic Acids, etc., Distribution of Intensity in the, A. R. Normand, J. B. M. Ross, and E. Henderson, 302; Soft, T. H. Osgood, 817; Spectrometer, An Unclaimed, P. E. Klopsteg, 14; Spectroscopy, Dr. A. E. Lindh, 440

X-rays: Irregular Emission of, D. Nasledow and P. Scharawsky, 508; on Micro-organisms, The Secondary Action of the, J. J. Trillat, 183; The Scattering of: Prof. P. Debye, 474; and the *J* phenomenon, B. L. Worsnop, 836

Yakutsk Republic, Contributions on the Resources of the, 612

Yeast Cells, Idophenol Oxidase of, Influence of Carbon Monoxide and Light on, D. Keilin, 670

Yolk Formation in some Arthropods, Mian Tasdique Husain, 817

Yorkshire Ammonites, Dr. L. F. Spath, 543

Zeeman Effect, The, and Spherical Harmonics, Prof. C. G. Darwin, 801

Zellteilung physiologisch betrachtet, Das Problem der, Prof. A. Gurwitsch, 556

Zonal Aberrations, Measuring, C. Beck, 440

'Zoo,' The Modern: 675; T. H. Gillespie, 747

Zoological: Gardens, A Public, to be formed by, G. B. Chapman, 502; Nomenclature: Changes in, 577; Consideration of Six Cases in, Dr. C. W. Stiles, 817; Society's: Gardens, Opening of the New Reptile House of the, 934; of London: Presentation of the bronze medal of the, to E. Bowman, 790; Progress of the, 171; Purchase of an Estate for a Zoological Park and Sanctuary, 468

Zoologie: Allgemeinen, Grundriss der, fur Studierende, Prof. A. Kuhn. Zweite Auflage, Mar. 5, Suppt., 4; Handbuch der, eine Naturgeschichte der Stamme des Tierreiches. Gegrundet von Prof. W. Kukenthal, Herausgegeben von Prof. T. Krumbach. Vierter Band. Erste Lief. Zweite Lief. Funfter Band. Dritte Lief., Mar. 5, Suppt., 3

Zoologisches Worterbuch: Erklarung der zoologischen Fachausdrucke; zum Gebrauch beim Studium zoologischer, anatomischer, entwicklungsgeschichtlicher und naturphilosophischer Werke, Prof. E. Bresslau und Prof. H. E. Ziegler. Dritte Auflage, 632

Zoology: A New Approach to, 631; General, The Elements of, a Guide to the Study of Animal Biology, correlating Function and Structure; with Notes on Practical Exercises, Prof. W. G. Dakin, 631

A WEEKLY ILLUSTRATED JOURNAL OF SCIENCE.

> *"To the solid ground*
> *Of Nature trusts the mind which builds for aye."*—WORDSWORTH.

SATURDAY, JANUARY 1, 1927.

CONTENTS.

PAGE
River Pollution and Fisheries 1
The Origin of Civilisation in America. By Prof. G. Elliot Smith, F.R.S. 3
Lignin and Lignification. By C. F. Cross, F.R.S. 5
War Record of the Survey of India. 7
Our Bookshelf 7
Letters to the Editor:
  The Origin of an Albino Mutation in *Limnaea peregra*.—Prof. A. E. Boycott, F.R.S., and C. Diver 9
  Active Nitrogen.—Dr. R. C. Johnson . . . 9
  A Suggested Interpretation of Certain Cases of Anisogeny.—R. J. Chittenden and Caroline Pellew 10
  Chinese Alchemy.—Prof. J. R. Partington . . 11
  Formation of Calcareous Tubes round the Siphons of Teredo.—Dr. C. M. Yonge 11
  Fluctuations in the Abundance of a Species considered Mathematically.—Dr. Alfred J. Lotka; Prof. Vito Volterra, For. Mem. R.S. . . . 12
  The Polishing of Surfaces.—F. W. Preston; James M. Macaulay 13

River Pollution and Fisheries.

ANGLING in the slow-running rivers of England affords recreation for an ever-increasing number of artisans and other responsible citizens of our large industrial centres. Inexpensive opportunities of health-giving open-air amusements in the limited time they have available are becoming fewer as the population increases and greater distances have to be traversed before arriving beyond the outskirts of the cities. Since it is upon the health and contentment of the city and industrial workers that the prosperity of the country has come to rest, it has become a duty of the nation to conserve the facilities for this tranquil and pleasant pastime quite as much as to conserve the more valuable salmon and trout fisheries, all of which suffer from the effects of pollution by industrial and other effluents more and more as time goes on.

With these objects in view, the Standing Committee on River Pollution was appointed in 1921, and, with the help of local sub-committees, and a growing weight of public opinion, it has already accomplished a great deal towards checking an increase in pollution, and in some cases in ameliorating the existing conditions. The problem with which the Committee is faced is not a simple one; it is not obvious how, in many cases, an industrial effluent can be rendered harmless, or sufficiently non-toxic and clear, so as not to damage life in the river or the amenities of the country-side. Every such effluent must go somewhere or the industry be dislocated; its satisfactory treatment in the space available at reasonable cost frequently provides matter for research.

An interesting problem of the moment is the satisfactory treatment and disposal of the large volume of water used for washing and transportation in the new beet-sugar factories. This wash water, besides dirt, contains organic matter in solution and suspension which, although comparatively harmless to fish life on leaving the factory, may become harmful owing to the development of toxic substances during the decomposition of the organic matter.

It is often easy enough to determine whether a river is polluted, but quite another matter to gauge the extent to which life in the river will be damaged. Fish utilise as food a large number of organisms, animals as well as plants. The larger animals, such as the fresh-water shrimp and insect larvæ, which serve as food for many species of fish, in turn feed on smaller animals and plants. In many cases the dependence of one on the other is direct and obvious: in others less so. The presence or absence of vegetation, even of the smallest forms such as diatoms, may play a considerable rôle in determining the conditions of life in a river, quite apart from their actual food value, since they afford harbourage to animals and assist in the self-purification of the water. Hence it is clearly not the direct physiological effect of a polluting effluent upon fish alone which has finally to be determined, but its effect, if any, upon some necessary link in the food-chain and upon the flora.

The need for the solution of problems such as these before satisfactory legislation can be introduced to cope with river pollution is obvious, and has been felt in countries other than England. In 1920 the Dutch Government established a central institute at the Hague for experimental work in connexion with waste waters generally, from which advice is now sought by local authorities administering the law against pollution of the canals and waterways, and by industrial associations seeking the most economical means of treating their effluents. In the United States many rivers are grossly polluted; for example, the river carrying the Chicago sewage is stated to be devoid of dissolved oxygen for a distance of twenty miles. There the question of rational legislation is beginning to attract attention, and many specific problems are presenting themselves. Since the laws of the country have allowed the rivers to be treated as a public sink, and in consequence vested interests in them as such have developed, it will doubtless be a difficult and very expensive task to cope with their purification.

In Great Britain numerous surveys of rivers have been carried out and local pollutions investigated during the last five years by Dr. E. C. Jee, the technical adviser to the Standing Committee on River Pollution, and by several scientific workers resident in various districts. Upon the results of this work, action has been taken in a number of cases and has led to the abatement of nuisances, and the fact that sources of pollution are being investigated at intervals and reported upon undoubtedly acts as a deterrent against increased pollution in other cases.

Besides this necessary survey work and investigation of local problems, a small scientific staff at the Fisheries Experimental Station, Alresford, have begun several lines of research fundamental to a proper scientific attack of many existing problems. With the final object of undertaking a complete biological survey of a river with particular reference to the effect of various pollutions upon the normal fauna and flora, methods have been evolved which aim at providing a quantitative, or, at any rate, comparable, measure of the abundance of life in different rivers or in the same river at different times of the year. Preliminary work showed that by far the greater proportion of the animal life (in the upper waters of the Itchen) lived either on the bottom or among the weeds which clothe it; ordinary dredges did not yield a representative sample. To obtain a representative sample of the smaller animals a frame with gauze bottom containing stones, etc., similar to the river bottom, was left for a week in the river, and the organisms which had migrated into it were then picked out and counted. It is anticipated that the various methods evolved will be of service in the examinations of polluted rivers, and also that results obtained will finally provide a valuable basis for comparison.

Fish found dead are frequently posted to Alresford for examination, and as our present knowledge of fish disease is fragmentary and the fish often arrive after decomposition has commenced, giving rise to symptoms which may easily be mistaken for those produced in a fresh fish by poisoning, an attempt is being made to obtain further accurate knowledge of post-mortem conditions, particularly histological changes in the gills and alimentary canal due to poisoning.

The need for investigations of a general nature is amply borne out; the Standing Committee on River Pollution in its recent report[1] states that it is "constantly faced with the lack of scientific knowledge necessary to devise a method of dealing with a particular effluent," and advocates the appointment of sufficient technical staff to elucidate, not only in the laboratory, but also by experiments at the source of pollution, the scientific questions which at present have no answer.

The future of many rivers in Great Britain is clearly in the hands of the chemist and biologist, for it is upon accurate knowledge such as they alone can obtain that any satisfactory legislation must rest. The longer the necessary efforts to tackle the pollution problem in a comprehensive manner is put off, the more difficult and the more expensive will be the task and the greater the risk of failure.

---

[1] "River Pollution and Fisheries. A non-technical report on the work during 1925 of the Standing Committee on River Pollution." Ministry of Agriculture and Fisheries, London. 1926. Price 6d.

To allow the serious pollution which exists at present in some British rivers to continue more or less unchecked and to grow, which it undoubtedly will tend to do as the population and industries increase, is an evil greater than can be expressed in terms of decreased monetary value of the fisheries. Increased demands on the water supply in towns and cities as they enlarge have also to be considered. From before the time of Isaac Walton the rivers of England have been part of the nation's playground, a playground put to greater use as the population becomes denser, a heritage to preserve—unpolluted.

The Origin of Civilisation in America.

La Esfinge Indiana: antiguos y nuevos aspectos del problema de los origenes americanos. By Prof. J. Imbelloni. Pp. 399+19 plates. (Buenos Aires: Libreria "El Ateneo," 1926.) n.p.

ALTHOUGH there is no reference to W. H. Prescott in this book, its title, "The Indian Sphinx," and the author's frequent references to himself as the Oedipus who is solving the riddle, suggest that Prescott's famous book "The Conquest of Mexico," which was published in 1843, had made a stronger impression upon him than he is prepared to admit. Both in the introduction and the lengthy appendix, Prescott gave an impressive summary of the evidence which forced him to admit, although it is clear he was very reluctant to do so, "that the coincidences are sufficiently strong to authorise a belief that the civilisation of Anahuac was in some degree influenced by that of Eastern Asia." At the same time, perhaps from having read Robertson's History, he was puzzled to account for the scores of arbitrary likenesses between the customs and beliefs of ancient Mexico and Asia. Thus he wrote:

> "Was it [the pre-Columbian civilisation of Mexico] indigenous? or was it borrowed in some degree from the nations in the Eastern World? If indigenous, how are we to explain the singular coincidence with the East in institutions and opinions? If Oriental, how shall we account for the great dissimilarity in language, and for the ignorance of some of the most simple and useful arts, which, once known, it would seem scarcely possible should have been forgotten? This is the riddle of the Sphinx, which no Oedipus has yet had the ingenuity to solve."

If there were any real scientific discipline in ethnology, one might have hoped that Prescott's two difficulties having now been removed by the advancement of knowledge during the intervening eighty years (which have also added a vast accumulation of evidence in corroboration of the clear implications of the statement in "The Conquest of Mexico"), the way would be clear for the frank admission of the diffusion of culture from eastern Asia. But in ethnology emotion still counts for more than reason: or perhaps it would be more explicit to say that the Newtonian principles of inductive reasoning, by basing theories on observed facts, have not yet penetrated into the subject, which is still under the sway of the deductive methods of Descartes. For in ethnology—and Prof. Imbelloni's treatise is a conspicuous illustration of the point—the dominating principle is still to force the evidence into conformity with certain catch-phrases that are called 'natural laws,' the *idées innées* of Descartes, the *Elementargedanke* of Bastian, the universal symbols of Freud, et cetera, from which a long line of philosophers, starting with Turgot in 1751, have been striving to rescue the study of mankind and make a real science of it.

For the introduction of confusion into the fascinating problem of the origin of the pre-Columbian civilisation of America, as indeed into all ethnological doctrine, the chief blame must be attributed to Dr. William Robertson, Principal of the University of Edinburgh, whose famous "History of America" was published in 1777. He seems to have been the first to give wide currency to the Cartesian ideas that are so popular in ethnology to-day.

> "When the people of Europe unexpectedly discovered a New World, removed at a vast distance from every part of the ancient continent which was then known, and filled with inhabitants whose appearance and manners differed remarkably from the rest of the human species, the question concerning their original became naturally an object of curiosity and attention. The theories and speculations of ingenious men with respect to this subject would fill many volumes: but are often so wild and chimerical that I should offer an insult to the understanding of my readers if I attempted . . . to enumerate or refute them." After mentioning some of these speculations he adds: "though they rest upon no better foundation than the casual resemblance of some customs, or the supposed affinity between a few words in their different languages, much erudition and more zeal have been employed to little purpose, in defence of the opposite systems."

Hence, without bothering to examine the evidence, the Scottish historian fell back on the device of formulating a law. "Were we to trace back the ideas of other nations to that rude state in which history first presents them to our view, we should discover a surprising resemblance in their tenets and practices; and should be convinced that, in similar circumstances, the faculties of the human mind hold nearly the same course in their progress, and arrive at almost the same conclusions."

I have made these quotations from the work of this eighteenth-century divine because they represent the stock-in-trade of those who claim the independence of American culture to-day. Hence they shed some light upon the interesting psychological problem of why theories that are in such flagrant conflict with the evidence should continue to be respected. The explanation is provided by the history of these fallacies. Although Robertson wrote his book more than twenty-five years after Turgot (who had acquired the Newtonian discipline of reasoning from Sigorgne, his teacher of mathematics), Scotland, as Buckle pointed out in his "History of Civilisation," still remained under the influence of Descartes and the deductive method. These ethnological fallacies were floating about for another century without being taken seriously, until in 1871 Sir Edward Tylor adopted them from Adolf Bastian, the arch-enemy of biological evolution, and gave them a fashionable and attractive veneer by calling them "evolution." By this strange irony more than fifty years ago, ethnology was put into the fetters of Cartesian scholasticism. These historical facts help us to understand how such a book as "The Indian Sphinx" could have been written.

The problem of the pre-Columbian civilisation of America, with which the book deals, is of crucial importance. Not only was it responsible, as I have just indicated, for shaping ethnological theory in the past, but also at the present it is the supreme test of clear thinking. It is becoming a habit on the part of those who defend the principle of the independent development (in other words, spontaneous generation) of culture, to pretend that they do not deny the reality of diffusion. But the American problem demands a plain answer to the question whether or not any cultural influence was conveyed across the Pacific Ocean during the first ten centuries of the Christian era. Did Mexico, Central America, and Peru derive the germs of their civilisation from Cambodia and Java fifteen centuries ago, or was it a wholly indigenous creation of the Maya and pre-Inca peoples? That is the clear-cut issue.

In this large treatise the various theories, ancient and modern, that relate to the origin of American civilisation are submitted to critical examination. In the first two-thirds of the book the author pours scorn on all theories of diffusion, adopting the extreme form of Bastian's theory of psychic unity. When the resemblances between cultures in different areas seem to put too great a strain on this speculation, he falls back on the biological theory of convergence. Hence it comes as a shock to the reader when on p. 279 he throws the *Elementargedanke* overboard and becomes an out-and-out diffusionist. He has no doubt that the Quechua and Aymara languages and the culture of South America were derived from Polynesia. The magic wand that seems to have effected this wonderful transformation is the fact that the name for an 'axe' (*toki*) and the mode of fashioning the implements are essentially identical in Oceania and South America. But having convinced himself of this fact he then proceeds to discover identities in other arts, customs, beliefs, and languages, and adopts whole-heartedly the methods he has been ridiculing in the preceding 270 pages!

This admission, however, creates new difficulties for Prof. Imbelloni. If certain words in the languages of Tonga, Samoa, and Tahiti are identical with those used in Peru, much more definite affinities can be detected in the languages of Indo-China and India. The derivation of the cultures of Oceania from India is widely admitted. Hence he is committed to the linking up of pre-Columbian American culture with that of India, which in the light of recent discoveries is known to be genetically related to those of Elam, Sumer, and Egypt. These links are all now well established, as Prof. Breasted has recently pointed out.

After an incomplete survey of the discussions of the seventeenth and eighteenth centuries, more than a hundred pages are devoted to certain modern speculations regarding connexions between America and Mesopotamia by way of Siberia and Turkestan, in the course of which essays on the evolution of the horse and the geographical distribution of the grape vine are introduced. The author examines and severely criticises Posnansky's attempt to apply to the ancient American pyramids astronomical methods for estimating their age somewhat analogous to those used by Sir Norman Lockyer in the cases of Stonehenge and Egyptian temples. Posnansky's calculation for Tiahuanacos gives a date of A.D. 1200, which seems not unreasonable: but Imbelloni says it is based on a series of errors.

Prof. Imbelloni's most scathing denunciations, however, are reserved for Part iii. of his book, in which he pours ridicule on what he calls "the Manchester School" and upon the present reviewer in particular. The bulk of this criticism follows the lines with which readers of NATURE have been made familiar during the last fifteen years, in particular in the discussion of the conventionalised elephant-heads on the Copan stela (see NATURE, November 25 and December 16, 1925, and January 27, 1916; also the interludes by Dr. Forbes and Mr. Robson in August 2 and September 13, 1924). As Prof. Imbelloni is not acquainted with anything that I have written on these matters since 1922 (most of his knowledge of my work having been derived from Dr. Germain's review in *L'Anthropologie* of that year), I need only direct his attention to the full statement on the elephant-problem in my book "Elephants and Ethnologists" (1924). But Prof. Imbelloni's indignation with me would be quite excusable if I had ever expressed the preposterous views he attributes to me when he says I pretend the Mayas and Peruvians came from Egypt! The confusion of race and culture vitiates in fact a large part of this entertaining book.

Prof. Imbelloni has rendered a very useful service in emphasising the remarkable identities between certain features of Mycenæan and Mexican architecture (Plate III.), Egyptian and Peruvian balsas (Plate XI.) (of which, unaware of the various memoirs I have written on ancient shipping, he seems to think I am ignorant), the monstrous figures (Plates XIV. and XV.) with projecting tongue in Italy, Polynesia, and Mexico (and he might have added India, Indo-China, and Indonesia), the wonderful terraces of the Philippines and Peru (Plate XVI.), et cetera. But it is very surprising that such striking illustrations of identity in arbitrary detail should be used as illustrations of convergence in that part of the book which is expounding the principle of the diffusion of culture from Polynesia to America.

At the present time scarcely any two believers in 'independent development' are in agreement as to the areas which are independent the one of the other. Prof. Imbelloni's book gives a new reshuffling. To illustrate the extent of these discrepancies I might mention that on the day his book came into my hands there also arrived a work by Prof. James H. Breasted, who admits the reality of diffusion from Egypt throughout the Old World, but refuses to admit any outside influence in America. Prof. Imbelloni denies diffusion in the Old World but admits that from the Pacific to America.

If we allow the negative parts of the two views to neutralise one another and admit the cases both writers have established by positive evidence, I think we shall arrive at the truth.

G. ELLIOT SMITH.

Lignin and Lignification.

Die Chemie des Lignins. Von Dr. Walter Fuchs. Pp. xi+327. (Berlin: Julius Springer, 1926.) 18 gold marks.

THIS monograph on a subject of outstanding interest will commend itself under its sectional title to a wide circle of workers as an important and timely critical survey. The author's treatment of the matter, however, is much more comprehensive than might be inferred from the title, for it embraces the full perspective, and the work is consequently a contribution to natural history, and, beyond the phenomenal aspects of plant life, to general philosophy. The scope of the monograph, in fact, is first to set out the very considerable chemistry of lignin resulting from the investigations of some three hundred workers whose researches are critically reviewed in the text, and then to re-examine the scientific material thus accumulated, critically selected and co-ordinated by the author, in relation to the several sections of the science of botany, systematic (classification), physiology, structure and histology, to modern conceptions of the ultimate structure of the forms of matter, to the scientific technology of industry, and thus implicitly to the philosophy of the human story, intimately interrelated as it is with that of plant life and evolution.

The philosophic note is struck early in a critical discussion of the well-known methods of identifying lignin in plant tissues, and the resulting definition of "Das genuine Lignin" as distinct from the $N-1$ lignins isolated by chemical treatment, which are either synthetic derivatives or modified forms of the actual or original lignin, the degree of change associated with the reaction mechanism of the process of separation requiring to be estimated, but necessarily by a method which is inconclusive in respect of the actual relationship. It certainly leaves undefined the mode of union of lignone to cellulose in the ligno-celluloses; and the author's treatment of this problem in the later chapters will impress upon the chemist of objective mentality the obvious but much-ignored consideration that the synthetical operations of the plant in respect of its organised cell structures are not of the order of reversible reactions of his systematic text-books.

A short outline of the work in sequence of chapters is necessary to characterise more closely its scope. Chaps. i.-iii. are concerned with (1) the identification of lignin *in situ*; (2) the isolation by various methods, direct (conversion to derivatives rendered soluble) and indirect (breakdown of associated cellulose to soluble products); (3) analysis, that is, elementary composition and estimation of 'adjective' substituting groups, and a critical comparison of the numerous 'lignins' thus separated with the genuine or ideal lignin of the organism. Chaps. iv.-vii. deal with the further special chemistry of lignin: conversion to synthetical derivation involving reactions of OH, CH=CH, CO and COOH groups, esters, ethers, halogen derivatives, condensations with phenols, reactions with oxidants and hydrogenants: hydrolyses and alkali fusions.

This *exposé* of the 'pure' or rather detached chemistry of lignin, occupying the first two hundred pages, is the author's critical digest of the literature of the subject of the period 1900–1926 (January 1), a delimitation set out in the preface. It is accurate and exhaustive of the period though not of the subject matter, for the antecedent period (1875–1900) contributed quantitative methods of fundamental value as such, but of further import when interpreted as establishing the conception of 'ligno-cellulose' by contrast with a cellulose extrinsically 'encrusted' with lignone matter. Moreover, it was clearly indicated, both *a priori* and on exact data, that the prototypes of the ligno-celluloses are the simpler structural forms of annual growths; whereas those of perennial structures are much more complex as such and by reason of secondary interior modification and condensations. The later research work dealt with in the present volume is largely devoted to the latter more complex types, which has inevitably complicated the treatment of the subject.

To resume on the author's sequence of subject matter: in Chaps. viii.-xi. the subject is developed in terms of biochemical science and illuminated by a sustained argument which shapes the matter, treated in all its related aspects, to the satisfactory issue of converging proofs of definite theory.

The subject of these chapters is lignification as an organic process: first, in relation to systematic botany; that is, to the grades of differentiated organic structure from the Thallophytes, with the first appearance of lignification in the Pteridophytes, to the most highly elaborated Phanerogams.

Histological investigation has already recognised an ascending series of types of lignification in close correlation with the evolution of structure; but the author points the way to a positive biochemical treatment of this enormous range of material, hitherto classified certainly without direct reference to lignification. As an illustration of such biochemical method, he briefly discusses the prolonged investigations of Carl Mez, applying his sero-diagnostic processes to the exploration of generic affinities (*Bot. Arch. Königsberg*, 1911 *et seq.*), pointing out, however, that the method is indirect and otherwise subject to error. It is clear that the body of exact knowledge of lignin, the subject of the preceding chapters, supplies a basis of re-investigation of the vegetable kingdom, by indirect method, which he predicts will establish *Ligninbildung* as a critical index of evolutionary development; and outside this objective of science such re-investigation promises a number of collateral developments.

In the next chapter, ix., under the sub-title "Entwicklungs-Mechanik," the organic process implicitly postulated is considered in relation to its factors. Lignification is a primary vital effect, but developed paradoxically *pari passu* with loss of vitality and cessation of growth. But the author refers to a 'post-mortem' activity which supervenes, a respiratory consumption of oxygen at the expense of elaborated cell-wall material; the removal of oxygen followed by complicated condensations, yields as a final product the lignin or lignone complex. It is suggested that the arena and basis of these transformations is the middle lamella of the cell-wall, and evidence of the contributing functions of its pectic components is afforded by the special chemistry of this group of carbohydrate derivatives established by later researches which are fully discussed.

In further development of the conception of the lignin-cellulose complex or ligno-cellulose as a biologic unity or individual, the author boldly grapples with the problem of cellulose constitution. While giving full value to chemical methods and results, attention is rather directed to the physical-biological interpretations of Rontgen spectrographs, to the ultimate configuration of an anisotropic colloid, as a 'cristallite' in evolution to organic form through micellar growth. This text definitely formulates a cellulose lattice and a penetration of the isotropic lignone so intimate as to represent a pseudomorph.

Chap. x. deals with the transformations of the ligno-celluloses and generally of cellulosic structures in fulfilment of ultimate natural functions.

In regard to lignone proper, this is characterised by its well-known extraordinary resistance to reaction, and the only change in living structures which can be traced is in contributing to the formation of phyto-melan. The enormous range of breakdown processes which result in humus, peat, and the various grades of coal, are discussed with general reference to lignin, and also the author's theoretical conceptions in the foregoing text, with reference both to cellulose, pectins and hemi-celluloses, and to the constitution of the lignone complex.

Chap. xi., under the title "Theorien uber Lignin," is a concentrated summary; that is, the author's conclusions on the whole matter.

Chap. xii., and last, is particularly noteworthy. The subject is the technology of lignin and gives the author's scientific rationale of the leading industrial processes for the treatment of ligno-celluloses, such as destructive distillation, pulp manufacture by both acid and alkaline processes, partial resolution of ligno-cellulose structures (cereal straws) to serve as cattle food-stuffs, the production of sugar from wood and wood residues. Avoiding details of the manufacturing processes, the author applies his reasoned conceptions both of the proximate and of the ultimate constitution of ligno-cellulose matter to the elucidation of the reaction mechanism of the several industrial processes. This discussion has distinction as a critical illustration of the sound method of applying science to industry.

In applying, in effect, the most modern and apparently recondite principles of modern science, the text of this chapter should be extraordinarily stimulating to those engaged in industry; not merely in perfecting routine operations but also in devising developments towards realising the progress inevitably suggested by discussion in relation to first principles.

It will be clear from the foregoing that the author has produced a work based on an unusual range of appreciative study of the sciences in their most recent developments contributing to the elucidation of the general theme, which, primarily indicated by its title, extends to the natural history of the vegetable kingdom.

We note in the text a considerable contribution of original investigations, which will probably be the subject of special publications in scientific journals. Lastly, the author is restrained in his criticisms of the researches of his fellow-workers; but a careful study of this work suggests that a notable proportion of the more speculative theories which they endeavour to establish will be excised from the student's memorabilia.

C. F. CROSS.

War Record of the Survey of India.

Record of the Survey of India. Vol. 20: *The War Record, 1914–1920.* (Published under the direction of Colonel-Commandant E. A. Tandy, R.E., Surveyor General of India.) Pp. xxv+155+27 plates +9 maps. (Dehra Dun: Survey of India, 1925.) 3 rupees; 5*s.* 3*d.*

SINCE its foundation in 1767, officers and surveyors of the Survey of India have accompanied every military expedition with which India has been connected. In order to provide a reserve of surveyors for war it has been the policy, as in most other countries, to employ army officers during peace time on the ordinary mapping of the country, so that they may be available at the outbreak of war to provide maps always required during the progress of military operations, though never so much as under the conditions which obtain to-day.

There is no essential difference between peace and war mapping except that in the former case the work is of a more deliberate character, while in war it has, of necessity, to adapt itself to the exigencies of military operations. Until the recent War, tactical topographical maps on a scale of a half or one inch to the mile sufficed, but now trench warfare imposes much larger scales. Artillery maps, also on large scales, require to be of the highest order of accuracy to be of any practical value, while accurate control is required for the location of enemy guns. These new duties have largely enhanced the importance of the surveyor's work in war.

On the outbreak of the War the Survey of India found itself in a position to provide, at once, officers and surveyors proficient in their art ready to take the field in accordance with its long-standing traditions. As the War went on, the call for officers became so insistent for survey and other duties that of the 54 regular officers employed in the Survey of India, 49 went on active service outside India. Of these eight were killed—all officers of the Royal Engineers—and eleven wounded. Of the 44 civilian officers who took part in the War, two were killed and two wounded. In addition, five Indian surveyors and 44 *khalasis* lost their lives in the service of the Empire.

The volume before us is a record of the operations carried out by the officers and surveyors in Mesopotamia, Kurdistan, Macedonia, Arabia, Persia, Palestine, East Africa, and Afghanistan. These explorations and surveys were accomplished in face of many difficulties and in every variety of terrain, from the icy highlands of Central Asia to the waterless deserts of Persia and Arabia. The total area thus explored by members of the department, often in unknown and unmapped regions, is almost comparable to that of Europe, while trustworthy new surveys, based on fixed points, covered an area more than twice that of Great Britain. In addition to a graphic description of the adventures that befell the surveyors in many lands, there is much valuable technical information to be found in the reports as to the methods of survey adopted, suitable to the different situations which presented themselves, and as to the climatic and political difficulties encountered.

The larger portion of the volume is naturally devoted to operations in Mesopotamia and Persia, where by far the greater part of the mapping was carried out. It is a record of intense devotion to duty on the part of officers and surveyors; nor must we forget the Indian survey *khalasi*, whose devotion to duty, whether in peace or war, though occupying but a humble sphere, ranks high among the servants of Government.

A roll of honour is included, and there are a number of photographs illustrating the different types of country concerned, as well as a series of index maps showing the areas actually surveyed. On the whole, this is a most interesting history of survey in war, and its production reflects the greatest credit on all concerned.

Our Bookshelf.

A Text-Book of Inorganic Chemistry. By Prof. Dr. Fritz Ephraim. English edition by P. C. L. Thorne. Pp. xii+805. (London and Edinburgh: Gurney and Jackson, 1926.) 28*s.* net.

PROF. EPHRAIM has written a very modern "Textbook of Inorganic Chemistry," in which the names of Rutherford and Bohr appear in the twelfth line of the text, whilst Laue and the Braggs appear on p. 12 of

Chapter i. This preliminary chapter on atomic structure is followed by three chapters on the properties of the elements. These deal with the periodic system and with allotropy in its various forms, including the colloidal forms of the elements and the special manifestations of allotropy as they are developed in individual elements. Two general chapters are then devoted to the preparation of elements, under the convenient headings of non-metals and metals. The succeeding groups of chapters deal with halogen-compounds, oxides of hydrogen and of the metals, compounds of sulphur, selenium, and tellurium, the nitrogen, phosphorus and arsenic group, and the elements of the fourth group (with boron), whilst a final section describes "The Rare Earths, Alloys and Radioactivity."

The author set out to write an inorganic chemistry which should be as systematic and as readable as a good book on organic chemistry. He has achieved his purpose, in the first place, by assuming that his readers have already reached a stage of development at which they can safely be 'thrown in at the deep end of the bath.' His second device is to omit all systematic treatment of the metals. This makes his task an easy one, since every teacher knows that the chemistry of the non-metals is no more difficult than the chemistry of carbon, and that the memory work and the inevitable dictionary treatment of the subject begin to be troublesome only when he passes from the tiny cluster of non-metals in the top right-hand corner of the periodic table to the vast array of metals which occupy the remainder of the table. It therefore appears likely that the author will be called upon to complete his task by adding to the present volume, which is virtually a text-book of the non-metals, a further volume on the metals.

If these limitations are borne in mind, there is no doubt that a student who has already reached the standard of a pass degree, and wishes to find a suitable book to read in preparation for an honours degree, will find Prof. Ephraim's text-book extremely useful and stimulating. The translation has been issued in a luxurious style, with beautiful print and on thick white paper with ample margins. The cost of the book is therefore not excessive, but it is possible that the student might prefer a less bulky volume, issued at a rather lower price.

Institut International de Chimie Solvay. Deuxième Conseil de chimie tenu à Bruxelles du 16 au 24 Avril 1925. Structure et activité chimiques: Rapports et discussions. Publiés par MM. les Secrétaires du Conseil sous les auspices de la Commission scientifique de l'Institut. Pp. xiv+672. (Paris: Gauthier-Villars et Cie, 1926.) 96 francs.

An account of the second conference of the Institut International de Chimie Solvay, held in Brussels on April 16-24, 1925, has already appeared in these columns (May 23, 1925, p. 817). It is therefore only necessary to note briefly the publication of the official report of the conference. This includes individual reports by Sir William Hardy, Sir William Bragg, Prof. W. L. Bragg, and M. Duclaux, on the structure of primary films, of crystals, and of solid colloids, and reports by Prof. Lowry, Prof. Swarts, M. Tiffeneau, Prof. Perrin, Prof. Job, Dr. Rideal, Dr. E. F. Armstrong, Prof. Moureu, Prof. Armstrong, M. Duclaux and Prof. Euler on various aspects of the mechanism of chemical change. These reports, with the somewhat lively discussions which followed them, make up a volume of nearly 700 pages, which will be read with interest by many of those who did not enjoy the privilege of attending the Conference. The publication of so full a report represents a vast amount of work on the part of the editors, and they are to be congratulated on the successful completion of their task. The only obvious criticism of their work is that in the index to the volume they have introduced two novel examples of multiple personality, by ascribing one report to MM. M. Eric et K. Rideal, and another to the triple authorship of MM. Thomas, Martin et Lowry.

One constructive suggestion may be made. Since the reports were first written in English or French, according to the nationality of the author, it would be a real advantage to be able to read them in the original language rather than in a necessarily imperfect translation. The printing of the final report in alternating French and English sections would surely not be a serious handicap to Belgian and French readers, whilst to English and American readers it would give a guarantee of authenticity and precision of phrasing that would be of even more value than the greater facility of reading in one's mother-tongue instead of in a foreign language.

L'Art et la religion des hommes fossiles. Par G.-H. Luquet. Pp. 231. (Paris: Masson et Cie, 1926.) 4*s.* 4*d.*

M. Luquet is a stern critic of facile theorising, and he will have none of the wholesale application of analogies from the practices of primitive people to the interpretation of the facts of palæolithic culture unless supported by internal evidence. Witness his treatment of the theory that the figures of animals carved, engraved, and painted were designed with the object of the magical increase and control of the game supply. This, he maintains, can only be asserted when the animal is represented as smitten by the weapon of the hunter. He leans definitely, therefore, to the view that while the magic employment of art may be predicated of the Magdalenian period, it scarcely exists, if at all, in the Aurignacian period. When once the possibility of representation had been grasped, it was practised for its own sake, it was purely æsthetic, and its magical uses were secondary. In the same way he refuses to accept the grosser form of female representations as evidence of a mother goddess cult, but regards them as erotic. The group of women encircling a male figure at Cogul, usually regarded as a ceremonial dance, is discussed at some length. Every aspect of palæolithic art, the cult of the dead and religion and magic, he touches upon in similar vein. M. Luquet's treatise is, with its cold logical outlook, certainly stimulating, though not always convincing. With no desire to dogmatise, it may very fairly be said that the weight of evidence as we know it at present is in favour of the magical rather than the purely æsthetic character of primitive and prehistoric art. As a corrective, however, to over-hasty enthusiasm, M. Luquet's book should be pondered by every student of prehistoric culture.

Letters to the Editor.

The Origin of an Albino Mutation in *Limnaea peregra*.

THE normal colour of the head, mantle, and footsole of the pond-snail *Limnaea peregra* is a yellowish grey of variable intensity which is clearly visible through the horn colour of the shell. The eyes are black. During the course of our experiments with the sinistral form of this snail (*Jour. of Genetics*, 15, 113) a new mutant has appeared in which the head, mantle, and footsole are yellow and the body has no melanin anywhere. The eyes are visible as brownish specks, contrasting with the deep black of the normal specimens. The appearance is presumably a diffraction effect of the lens, for microscopically there is in young specimens no retinal pigment, though in snails that have grown up and bred a little brown-black pigment can be seen in the retina. We call this mutant 'albino-body.'

Albino-body first appeared in a sixth generation brood from a single isolated (*i.e.* self-fertilising) normally pigmented sinistral snail (brood 1629). This brood at the time of counting consisted of 65 normally pigmented, 22 albino-body, and 74 dead, which of course could not be classified. Clearly the parent snail was heterozygous for the albino factor. This snail was one of a normally pigmented brood derived from isolated singles for three generations back. Eight pairs and seven other isolated singles were carried on from among its sisters and gave broods totalling 4859 young. In none of these 15 broods were any albinos found. Three of these broods were carried on to the next generation and 721 young obtained: again no albinos were found.

In terms of chromosomes, if isolated single (self-fertilised) snails are used, any new recessive mutation must make its presence apparent in the brood given by the first animal to contain the mutant chromosome. It seems clear, then, that the mutation occurred in one chromosome of the germ cells responsible for the parent snail of brood 1629.

Thirty-three snails from this brood were used for further breeding and gave the results set out in Table I. The albinos, as would be expected, bred pure for albinism. For the 27 pigmented snails tested as parents the expectation would be 9AA to 18Aa, the results on the most favourable basis give 10AA to 17Aa, on the least favourable, 12 : 15 (according to the actual composition of the pairs 7596 and 7599). The total classified young from the 12 mixed broods given by Aa parents is:

	Pigmented.	Albino.
	1825	607
Expectation	*1824*	*608*

There seems to be no differential infantile mortality, for whether the death-rate is 79 per cent. (7667) or 12 per cent. (7674) the agreement with expectation among the living remainder is equally close. Pigmented and albino snails come from the same capsule of eggs.

Accurate counts cannot be made with young that have only just hatched, but within a month or so the two types stand out remarkably clearly without any intermediates, and when spread out in the counting-dish give an excellent occular demonstration of the simple 3 : 1 ratio. The material might be useful to those engaged in demonstrating elementary Mendelism to classes. The technique of breeding the snails and counting the results is very simple, and, with only a few bottles, involves a negligible expenditure of time and money. Snails planted out in the spring will, under proper conditions, give broods that may be counted from August to November, and require no attention between planting and counting. There are large quantities of the albino strain at present available for distribution, if required. In the normal course of our experiments these will be thrown away in February.

Active Nitrogen.

IN the Research Items in NATURE for September 18 and in correspondence in the issues of October 23 and November 20, attention has been directed to experimental work by Willey and Rideal (*Jour. Chem. Soc.*, July 1926) which led them to suggest that active nitrogen consists of metastable molecules having an energy of about 42,500 cal. per gm.-mol. (= about 2 volts).

Such a view is, however, difficult, if not impossible, to reconcile with spectroscopic data. Ludlam and Easson have pointed out one type of difficulty in the case of the production of such a line as that at λ2061 in the iodine spectrum, which requires an energy of some 150,000 cal. for its excitation. In reply to this, Mr. Willey has suggested that a quasi-stable molecule may first be formed (such as N_2I_2)—presumably by impact of an active nitrogen molecule and an iodine molecule—the energy of which may be released by a second active nitrogen molecule and the total energy should be adequate to excite the iodine line. This, however, is scarcely possible, for the maximum energy which the break-up of the above semi-stable molecule could yield is that of the active nitrogen molecule which produced its formation. When this is added to the energy of the impinging active molecule it only gives as available energy of excitation twice that of a *single* active nitrogen molecule (which would, according to Willey and Rideal, be 85,000 cal.). In practice, the energy available for exciting the iodine line will be still less by the amount required to dissociate first the iodine molecule.

As an alternative Mr. Willey suggests that the excited NO molecules which yield the β and γ groups of the afterglow spectrum may be responsible for excitation of the line. In this particular case this is just possible, although it is near the limit which these molecules can possess. The (0, 0) band of the β group requires almost 6 volts for its production, and even taking the extreme case that an excited NO molecule is loaded with vibrational energy up to the point of dissociation, its available energy would be only 7·9 volts or 182,000 cal. (*vide* Birge and Sponer, *Phys. Rev.*, vol. 28, p. 283, 1926). In general, therefore, activated NO molecules cannot account for all the spectra which active nitrogen is known to be capable of exciting.

In accordance with the views expressed by Birge, Sponer, and others, it seems highly probable that active nitrogen is really atomic nitrogen, which is equivalent to an energy of 11·4 volts (= 263,000 cal.), and this appears as radiation in the ordinary process of recombination. Contrary to the implication of Mr. Willey in his letter to NATURE (November 20), this evaluation of the energy is not based primarily on the ability of active nitrogen to excite *other* spectra but on the nature of its *own* spectrum (*i.e.* the α group). The peculiar limitation of the first positive band spectrum, which it comprises, receives a natural explanation on the assumption that about 11 quanta of vibrational energy (= 2·1 volts) in addition to the 9·3 volts of electronic energy, are sufficient to effect dissociation of the N_2 molecule. Consequences which follow from this have been verified by quite different lines of experiment (*vide* Birge and Sponer, *loc. cit.*).

In explanation of their theory that active nitrogen consists of metastable molecules excited to about 2 volts, Rideal and Willey write that "to effect this excitation it appears that the molecule has to be excited to a high level (11·5 volts) but the electronic energy rapidly disappears after departure of the gas from the discharge zone. . . ." This can scarcely be the case, for 2 volts energy are inadequate to account for the afterglow spectrum (α group), more especially as we now *know* that the final electronic state of the molecule after this emission is 8·0 volts above the normal.

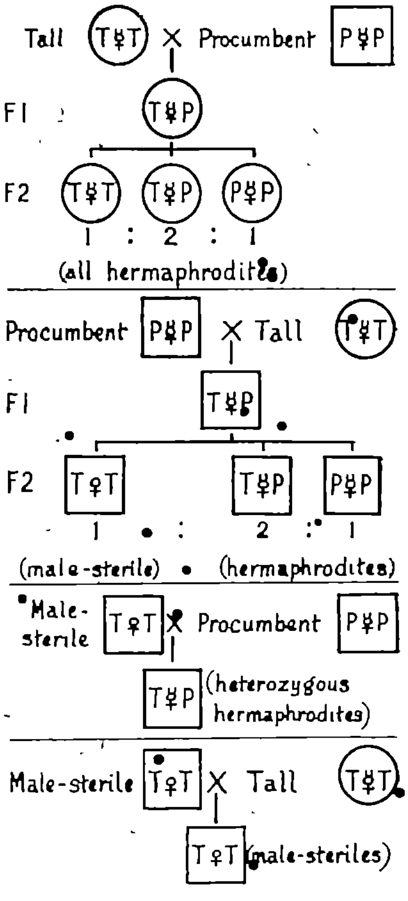
A Suggested Interpretation of Certain Cases of Anisogeny.

MANY cases are known in which the results of reciprocal crosses between green and variegated plants fail to agree. In all these cases the progeny reproduce the appearance of the female parent alone. Cases are also known in which a cross made one way between two true breeding green races results in variegation, whereas in the reciprocal cross the appearance of variegation is either deferred to a later generation or is absent. We know that the female contributes all, or the greater part, of the cytoplasm, and it has therefore been supposed that the cytoplasm, or its inclusions, is partly or wholly responsible for this difference in inheritance. Can this difference in the contribution of the male and female account for the dissimilar results of reciprocal crosses in other characters than variegation?

In crosses between the Tall and Procumbent races of ***Linum usitatissimum*** a peculiar abnormality (male-sterility) occurs in the F2, and is inherited as a simple Mendelian recessive (Bateson and Gairdner, *Jour. of Gen.*, 11, 3, 1921). This character only appears when Procumbent is the female parent in the original cross. No male-steriles occur in F1 or F2 of the reciprocal cross of Tall by Procumbent. Male sterility, then, only appears when there is cytoplasmic continuity from Procumbent.

We suggest that this difference in inheritance is due to a dissimilarity in the cytoplasms of Procumbent and Tall. Individuals of the F1, and later generations resulting from the cross of Procumbent by Tall, would have cytoplasm contributed by Procumbent, whereas the progeny of the reciprocal cross would have Tall cytoplasm. Though a particular Procumbent gene, or group of genes, reacts normally in both cytoplasms, the corresponding factor, or factors, in the Tall, when homozygous in Procumbent cytoplasm, gives rise to male-steriles.

This may be shown diagrammatically thus:



○ — cytoplasmic constituent of the Tall.
□ — " " Procumbent.
T — a gene, or group of genes, of the Tall.
P — a corresponding gene, or group of genes, of the Procumbent.

It will be noted that male-steriles crossed with the pure Tall race give only male-steriles. Hence the Tall race was considered by Dr. Bateson to be heterozygous for the element determining hermaphroditism, this element passing solely to the ovules, the pollen being devoid of it. Such phenomena of unlikeness in the genetical constitution of pollen and ovules Dr. Bateson called anisogeny, in opposition to isogeny, the normal state in which they are equivalent. The example of anisogeny in flax he attributed to somatic segregation occurring at the formation of male and female organs In the course of last year, however, he considered the possibility of applying a scheme similar to that above described and illustrated, but, owing to two or three inconsistencies in the experimental material, he was not wholly satisfied with it. The inconsistencies remain; but critical evidence is now available in flax, which, though incompatible with the original interpretation, is in perfect harmony with that now proposed. Additional evidence is also provided by a similar case of anisogeny in Geranium, observed here by W. C. F. Newton and Miss A. Sverdrup (unpublished).

It is perhaps needless to say that the present scheme does not apply to Matthiola, or at least does not do so in any simple form.

Chinese Alchemy.

IT is generally agreed that chemistry had its origin about the first century A.D. at Alexandria, where the Egyptian metallurgical and technical arts combined with speculative philosophy and theosophy to form a belief in the possibility of the transmutation of metals into gold. On the conquest of Egypt by the Arabs in A.D. 640 this knowledge passed to Arabia, largely through the intermediary of Syriac translations of the Greek treatises. Arabic chemistry is not earlier than the seventh-eighth century A D. and appears to be greatly dependent upon that borrowed from Alexandria

Berthelot ("Archéologie et histoire des sciences," Paris, 1906) considers that Chinese alchemy was derived from the Arabs He relies principally on a correspondence with Terrien de la Couperie, but the opinion of the latter is not quoted in detail. Since the late origin of alchemy in China which this implies is very definitely in contradiction to the Chinese accounts, Berthelot assumes that the latter are largely interpolated, and that the parts dealing with alchemy are additions made after about A.D. 700 He supports this theory by the statement that information about China is really comprised in eighteenth-century native editions of works not usually earlier than A D. 1000, that is, after the best Arabic period

There seems to be no evidence that Chinese alchemy is of Indian origin. The earliest treatises on alchemy in India are definitely later than the Arabic period and are probably based on Arabic sources, although if Chinese chemistry is earlier than this the possibility of Indian alchemy coming from China may be considered Writers on Chinese science, except Giles, all claim its originality, but they do not seem to be acquainted with the activity of the school at Alexandria, and generally assume that chemistry began with the Arabs in the eighth century A.D., which was the usual idea until Berthelot's publication of the Greek treatises of the Alexandrian school, portions of which had been published by Hoefer. The earliest of these are about seven hundred years before any chemistry was known to the Arabs. Giles ("Encycl. Britt." art China) states that Chinese chemistry is of Greek origin, but the date he gives for it, about 150 B.C. (in agreement with native accounts), is much too early for that source to be possible, unless there was a school of chemistry flourishing in Europe of which we have now no trace whatever. This is highly improbable.

The occupation of Taoist circles with the preparation of an elixir of life and the philosopher's stone is mentioned by Se-Ma-Tsien as prevalent in the reign of Wu Ti (140–86 B.C.). The accuracy of Se-Ma-Tsien seems to be unquestioned, and the account is nearly contemporary. Berthelot refers to this, but is forced to conclude that these Chinese accounts have been interpolated since A D. 700. It is stated in Chinese sources which are available in translations that Hoei-nan-tsze was an alchemist, and a chapter of his works called "On Bodily Things" deals with alchemy. A translation of part of this has been published by de Harlez and seems to confirm this, but one cannot be sure unless the whole account is considered. Se-Ma-Tsien also reports that a magician Li Siao Kiun advised the Emperor Wu Ti to sacrifice to the alchemist's furnace so that he could call on supernatural beings who would help him to change cinnabar into gold. If the dates are authentic, this is before the earliest alchemy otherwise known.

The most celebrated Chinese alchemist is stated to have been Ko Hung or Pao Pu Tse, who lived in the fourth century A D. This would be just about the period when the Alexandrian school was very active, and the possibility of his being influenced by it is rather important, but it is long before the Arabic period. He is said to have written a book called "Niu pien," part of which deals with alchemy. Berthelot refers to this text but doubts its authenticity Extracts from Ko Hung are published by Edkins (*Trans. China Branch Roy. Asiatic Soc.*, Hong Kong, 1855, part 5, pp. 83-99), whose memoir is practically the only source of information on the subject, and they indicate an advanced theory and practice of alchemy.

My object in directing attention to this subject is to make it clear that any conclusions which may be drawn as to the dates of Chinese texts which are based on the belief that accounts in them of alchemy must have come from Greek or Arabic sources are highly doubtful, since the actual position is uncertain. A consideration of all the information on Chinese alchemy which is available to me in European languages has left me with the conviction that the matter is still quite open and that any other view, such as the one adopted by Berthelot, is doubtful. It is to be hoped that the attention of competent Chinese scholars may be attracted to what would be a most interesting and valuable period in the history of chemistry.

Formation of Calcareous Tubes round the Siphons of Teredo.

AT the beginning of June 1926 a quantity of wood heavily infected with Teredo (probably all *Teredo norvegica*), taken from the experimental rafts moored near the Plymouth breakwater, was placed in one of the tanks in the Plymouth laboratory. It was left undisturbed for almost four months, and when examined at the end of September was found covered with fæcal deposits consisting of wood fragments cut away by the shell valves of Teredo and passed out by way of the exhalent siphons. These deposits were, on the average, rather less than half an inch thick, and when they were washed away there were revealed, projecting from the wood, great numbers of fine calcareous tubes, which on closer examination proved to occur always in pairs and to project from the openings of the burrows formed by the shipworms. Plainly the tubes had been formed around the siphons of the Teredo. They were of varying length, depending presumably on the thickness of the deposits, the longest being some two-fifths of an inch. The general appearance of the wood is shown in Fig 1.

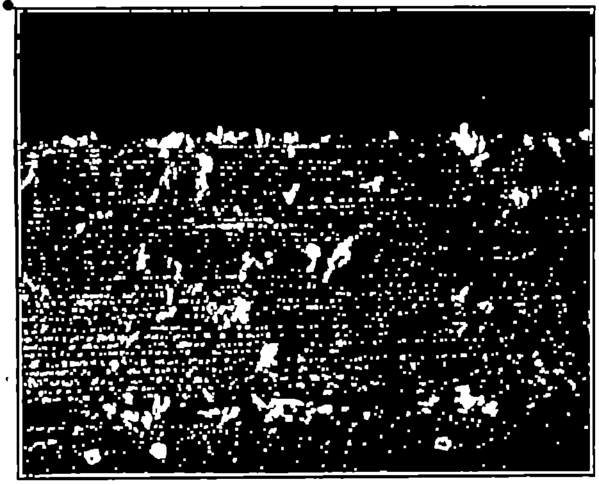

Photo.] [*A. J. Smith.*

FIG. 1.—Portion of wood badly infected with *Teredo norvagica* The white objects are the protruding calcareous siphonal tubes which appeared after the fæcal deposits had been washed off. In several cases the paired tubes can plainly be distinguished.

Normally the external openings of the tubes of Teredo are very difficult to distinguish, consisting of a pair of minute openings ringed with calcareous matter out of which project the siphons and within which these are immediately withdrawn on stimulation. The presence of fæcal deposits, which had accumulated to an abnormal degree owing to the lack of water currents to remove them, would tend to obstruct the passage of the siphons and so endanger the life of the animals within. The response of the animals to this abnormal and dangerous state of affairs was to lay down calcareous tubes around the siphons, which by this means were able to maintain free contact with the water.

Dr W. T. Calman has directed my attention to the fact that the giant shipworm, *Kuphus arenarius*, which lives vertically embedded in the mud of mangrove swamps in the Pacific, normally has the siphons encased in this manner, a fact which was known to Rumphius so far back as 1741, and was figured by him (as *Solen arenarius*) in his "D'Amboinsche Rariteitkamer" This animal lives normally under conditions in which the Teredo in the Plymouth tank lived for some four months, namely, in constant danger of being suffocated by accumulating deposits—in one case of mud, in the other of fæcal matter.

This accidental production of calcareous siphonal tubes in Teredo is therefore of some considerable interest, since it provides a very striking case of an immediate and highly successful response by an animal to changed environmental conditions; a response, moreover, which has taken the form of a permanent adaptation in related animals living under conditions very similar to those accidentally produced.

Fluctuations in the Abundance of a Species considered Mathematically.

WITH regard to Prof. Volterra's interesting article, "Fluctuations in the Abundance of a Species considered Mathematically," in NATURE of October 16, page 558, I may be permitted to point to certain prior publications on the subject, of which Prof. Volterra seems to be unaware. The general theory as well as a number of special cases have been set forth in "Elements of Physical Biology" (published by Williams and Wilkins, Baltimore, 1925), in which work a considerable number of references to the journal literature are given. Among other things Prof. Volterra's diagram "Fig. 2" will be found on page 90 of the book cited; the expression for the period of isochronous small oscillations in the case of two species is also found on the same page. Prof. Volterra refers to certain applications of his analysis to problems of sea fisheries, to a passage in Darwin's "Origin of Species," to extinction of species, to pathogenic germs, and to parasitology. An application to sea fisheries is found in the book cited on page 95, to a passage in Herbert Spencer on page 61; to the extinction of species on pages 94, 95; to pathogenic germs on pages 77, 79, 147 *et seq.*; to parasitology on page 83.

The effect of introducing a third species into a system of two species is discussed on page 94; the effect on equilibrium of changing various factors is treated in Chap. xxi., "Displacement of Equilibrium," and, in particular, the effect on equilibrium between food and feeding species is analysed on page 289. The distinction between oscillatory and aperiodic systems, and its relation to certain quadratic forms, is referred to on pages 146, 148, and 159.

It would be gratifying if Prof. Volterra's publication should direct attention to a field and method of inquiry which apparently has hitherto passed almost unnoticed.

ALFRED J. LOTKA.

Metropolitan Life Insurance Company,
New York City, October 29.

In the above letter from Dr. Lotka, which is in accordance with our preceding correspondence, following upon the publication of my article in NATURE, he justly observes that he had obtained the differential equations in the case of two species, one of which feeds upon the other, that he had given, as well as myself, the same diagram of the integral, and also the period in the case of small fluctuations. In this I recognize his priority, and am sorry not to have known his work, and therefore not to have been able to mention it.

I did not even know other publications of the same kind by other authors, for example, the work of Sir Ronald Ross on malaria, which precedes the writings of Dr. Lotka, who has, however, found so many new and important results.

The other observations mentioned in the above letter refer to points which I have not treated; but as to the sea-fisheries, while I refer to the laws (which I believe to have been the first to formulate) and principally to the third law, which gives an easy way of calculating the maximum output of fisheries; he, on his part, considers the case of the addition of a third species, which seems to me a different problem.

I also think that the quotation of Darwin's acute intuition referring to my third law, and the quotation from Spencer, which touches only the principle of the existence of fluctuations, are essentially different.

I think that the study of the general case of the convivence of *n* different species, subject to the hypothesis which permits me to distinguish the case of conservative association from that of dissipative association, and to obtain integrals and laws of fluctuation which form the essential and the greatest part of my memory, is absolutely new. To conclude, I recognize the existence of some common points in Dr. Lotka's work and my own, in which he has priority, but my work and his diverge in all the rest.

Working independently the one from the other, we have found some common results, and this confirms the exactitude and the interest in the position of the problem I agree with him in his conclusions that these studies and these methods of research deserve to receive greater attention from scholars, and should give rise to important applications.

VITO VOLTERRA.

Via in Lucina, 17,
Rome, November 27.

The Polishing of Surfaces.

DR. HAMPTON of West Bromwich has directed my attention to Mr. J. M Macaulay's letter on "The Polishing of Surfaces" in NATURE of September 4, p. 339.

In conversation with Sir Herbert Jackson, Mr. Twyman, and others, I have once or twice had occasion to point out that the energy available in practice for liquefying the surface layer of glass is many hundreds of times what is theoretically necessary. It is known that in polishing glass, the amount of glass removed corresponds to a solid layer of the order of ten wave-lengths in thickness. The total quantity of heat necessary to liquefy or even vaporise a layer of this thickness is not great in comparison with the energy expended in the actual process of polishing. The figure given by Sir George Beilby of four pounds per square inch as a pressure sufficient to start flow has no significance. In the process of polishing glass on a commercial scale, pressures very much less are the rule. In the polishing of plate glass, for example, they are of the order of half a pound per square inch, in the spectacle industry they are commonly of the same order; in the optical industry the specific pressures used become greater and greater as the surface becomes smaller

There is every reason to believe that glass will polish with the most insignificant pressures that can be attained in practice; but of course the lower the pressure the longer the time required. The coefficient of friction which Mr. Macaulay takes as 0·3 is a long way out. In polishing with felt and similar materials the coefficient ranges from about 0·85 to 1·1, and is usually taken by designers as from 0·95 to 1·0. In polishing with pitch the apparent coefficient of friction fluctuates very widely, because the film of moisture between the pitch and the glass renders the interfacial pressure itself either very great or very small according as the quantity of moisture becomes less or greater. However, whatever assumptions may be made about the pressures and coefficients of friction, it may be taken that in the polishing of large surfaces of glass about [illegible] kilowatt hour is expended over a square foot of surface polished. In the optical industry, where surfaces are smaller and preliminary grinding is better, an expenditure of energy of about half this amount suffices. From this it may be calculated, I think, that the efficiency of the glass polishing operation is (on the assumption that the energy is required for liquefying a thin surface layer) not more than about one-half of one per cent

I am not a great believer in the surface flow theory. In various papers to the Optical Society of England and elsewhere I have given reasons for believing that whatever part surface tension effects may play, the process of polishing is at bottom primarily one of abrasion.

F. W. PRESTON.

222 E. Clay St.,
Butler, Pa., October 26.

THE practical information which Mr. Preston gives is of considerable interest and value. His observations appear, on the whole, to support the view expressed in my previous letter, that glass surfaces are actually fused in the process of polishing.

One wonders whether the conception may not approximate in some degree to Mr. Preston's belief that "the process of polishing is at bottom primarily one of abrasion." One can imagine the surface molecules in the liquid state being, so to speak, picked off by the rouge particles, thus giving, so far as the resulting debris would indicate, an abrasion effect.

Origin of Yolk in the Eggs of *Luciola gorhami*.

THE eggs of the coleopteran fire-fly, *Luciola gorhami*, found in the plains of the Punjab, have proved to be objects of rare value for the study of the problem of the origin of yolk There are two kinds of yolk in these eggs. albuminous and fatty. The former arises directly from nucleolar extrusions of a remarkable type At a very early stage in the growth period the nucleolus shows signs of intense activity and buds off numerous round bodies of different sizes, which are thrown out in the cytoplasm. The nucleolus continues to throw out these extrusions until the very last stage in oogenesis At the beginning of this process the extrusions migrate towards the periphery of the egg-cytoplasm, where they grow in size, perhaps at the expense of food materials derived from the follicle cells

The whole process is reminiscent of what has been described in the cockroach and certain Hymenoptera, by Hogben (*Proc. Roy Soc.*, 1920, A, and 1920, B) and in Saccocirrus by Gatenby (*Quart. Jour. Micr. Sci.*, 1922). Nucleolar extrusions preceding the appearance of albuminous yolk have, of course, been described in some other eggs, e.g Lithobius (King, *Scient. Proc. Roy. Dub. Soc.*, 1924, and Nath, *Proc. Camb Phil. Soc. Biol. Sci.*, 1924) and Buthus and Euscorpius (Nath, *Proc. Roy. Soc.*, 1925), etc., but in Luciola it is noteworthy that the process of nucleolar budding lasts practically throughout oogenesis, and the process of the growth of nucleolar extrusions into the albuminous yolk spheres can be studied with diagrammatic clearness.

The origin of the fatty yolk from the Golgi elements is no less clear. The latter exist in the form of rings and crescents. The rings might also be appropriately described as vacuoles (cf. 'vacuome' theory of Parat), with a sharp chromophilic rim and a central chromophobic substance (idiosome). When the solid osmicated fat spheres are decolorised in turpentine they also show a chromophilic rim and a central chromophobic substance, exactly like the Golgi rings. On further decolorisation they appear like clear vacuoles.

We emphasise this morphological similarity between the Golgi rings and the fatty yolk spheres. It seems clear that the fat spheres arise directly from the Golgi rings, in the interior of which free fat, not miscible with the general cytoplasm, is deposited. In the undifferentiated germ cells the Golgi apparatus exists in the form of about four rings lying on the edge of the nuclear membrane, and we further emphasise the remarkable and unique fact that the Golgi rings of some germ cells are saturated with free fat long before the egg is differentiated from other cells.

A full account will be published later.

Solar Radiation and Athermancy.

THE efficacy of a material in excluding solar heat is a complex function. For practical purposes, however, athermanous materials may be graded in terms of an empirical transmission factor,

$$F = (1 - R)/\{1 + (1 + E_2)[1/(1 + E_1) + 1/K]\},$$

where K is the conductivity (B.Th.U. per sq. ft. per degree Fahr. per hour), E_1 the emissivity of the inner surface, E_2 the emissivity of the exposed surface and R its reflecting power for solar radiation. Both surfaces are presumed to be in contact with air. Values for a few materials are tabulated below.

Material	Inner Surface	Exposed Surface	E_1	E_2	R	K	F
Metal sheet .	Silvered	Silvered	0·02	0·02	0·90	large	0·05
1 in. wood .	White or black paint	White paint	0·95	0·95	0·70	1·0	0·08
3 in. wood .	„ „ „	Black paint	0·95	0·95	0·05	0·3	0·11
1 in. wood .	„ „ „	„ „	0·95	0·95	0·05	1·0	0·24
Metal sheet .	Silvered	Blackened	0·02	0·95	0·05	large	0·33
Metal sheet .	Blackened	„	0·95	0·95	0·05	large	0·48

It would be of interest to know whether there is any anomaly in this grading.

An Amusing Conception of Scientific Discovery.

THE want of touch between politicians and science, at all events a score of years ago, is amusingly illustrated in the following extract from the official report of a speech made by the Marquis of Lincolnshire in the House of Lords on Dec. 6 last.

He was speaking on the Small Holdings and Allotments Bill, and was describing discussions which, when Minister for Agriculture in Sir Henry Campbell-Bannerman's Government, he had with the Prime Minister about the introduction of the Bill which emerged as the Small Holdings and Allotments Act of 1908.

The extract is as follows :—

"Sir Henry Campbell-Bannerman pricked up his ears and said: 'What a curious thing it is how the same wonderful sentiments and ideas sometimes simultaneously strike the noblest minds. I will give you an instance. When I was at Cambridge in the 'fifties there was a great big hulking undergraduate at St. John's College. He must have been very clever because, going one starry night for a ramble, he looked up at the firmament on high and discovered a planet. It was a wonderful thing to do, but it was absolutely true that that man discovered a planet, and, curiously enough, that very same night an old Frenchman, squinting through an opera glass or a telescope or something of that sort, discovered it too.' And that, Sir Henry Campbell-Bannerman said, was a very wonderful development and almost a precursor of the *entente cordiale*."

It required an effort, at all events on the part of one reader, to recognise this highly original account of the simultaneous discovery of Neptune by Adams and Le Verrier in 1846.

An Unclaimed X-ray Spectrometer.

IN the hope that we may be able to restore a piece of lost property to its owner, we would greatly appreciate the publication of the following facts.

Recently the New York Central Railroad had an auction sale of unclaimed baggage. One of the pieces of baggage contained what appears to be a simple X-ray spectrometer with a fluorescent scale for visual observation. The purchaser brought the apparatus to us for identification, and he is willing to restore it to its owner if we can locate him.

The instrument was sent as baggage on the New York Central Railroad from Albany, N.Y., to Chicago, where it arrived at 10.00 A.M. on October 21, 1924, presumably on the Twentieth Century Limited. The date makes it appear possible that the apparatus may have belonged to someone who attended the meeting of the British Association for the Advancement of Science in Toronto. The instrument was manufactured by Schall and Son, of London.

Inquiries should be directed to the undersigned, who will take the necessary steps to have the instrument returned to its owner.

The Oogenesis of Lumbricus.

I FEEL compelled, much against my own and Prof. Gatenby's feelings, to reply to his letter in NATURE of December 11. In the first place, I do not quote in my bibliography papers which I have not carefully read. In the second place, I have read the papers on yolk formation which Prof. Gatenby recommends. Hence my desire for an attempt at co-ordination of the divergent observations on this phenomenon in oogenesis. Lastly, may I record my agreement with him on the subject of Harat's work? I think his evidence is very strong, yet, at the same time, I would prefer to "add facts" and "avoid discussion" of work which is even yet in its infancy.

'Sun Circles' in Ritual Dances.

IN connexion with Miss Violet Alford's lecture on ritual dances, reported in NATURE of December 4, it would be interesting to know whether anthropologists familiar with ritual dances among tribes of the southern hemisphere, for example, the Australians, have noted in these the practice of dancing 'sun circles' in the reverse direction, which we should call 'widdershins.' As the apparent path of the sun in the southern hemisphere runs in the contrary direction to its path in our hemisphere, that is, from east through north to west, sun circles should surely be danced in this direction also.

Regions of Compression.[1]

By Dr. J. W. EVANS, F.R.S.

I.

IT is usual to contrast the horizontal forces acting on the earth's crust with those that are vertical and to regard the latter as more fundamental and important. This attitude is apt to be misleading, although it rests on a foundation of fact, if it be true, as is generally believed, that most horizontal forces are ultimately to be attributed to the contraction on cooling of the earth's interior, which lets down the crust so that it has to accommodate itself to an area less extensive than that which it previously occupied.

The discovery, however, of the release of energy in the course of the atomic degradation of uranium and thorium and their products caused a reconsideration of the question. It is true that the amount of radioactive materials diminishes as the basicity of the rock increases, and there is every reason to believe that the deeper rocks are more basic than those nearer the surface, but it is contended that, even if this be allowed for, the energy given out by them in their disintegration, converted into heat, would cause a rise instead of a fall in the earth's temperature. Prof. John Joly believes that this has in the past led to catastrophic developments characterised by great outpourings of lava. But, although the whole of the energy given out by radioactive elements, when isolated, is converted into heat, it is probable that a considerable proportion of the energy liberated by such elements, when they occur as rock-constituents, is used up in effecting physical, chemical, or atomic changes in the surrounding minerals.

That much of the radioactive energy set free in the disintegration of radium and thorium is absorbed in other ways than in raising the temperature of the rocks is clearly shown by the formation in certain circumstances of 'pleochroic haloes' round radioactive minerals. This occurs especially in the case of zircon embedded in biotite mica. Such a halo is a sphere with a radius of about 30 microns, and has a minute zircon at the centre. It is of a darker and a deeper brown and far more pleochroic than the rest of the mica. The difference is usually assumed to be the result of ionisation by the radiations from uranium and thorium contained in the zircon. The possibility of atomic changes under the influence of the α rays must, however, not be ignored.

The formation of the haloes must involve a considerable absorption of energy, the magnitude of which will be realised when it is remembered that the mass of the halo may be some 15,000 times that of the zircon at its centre, and more than 300,000 times that of the uranium and thorium to which the halo owes its existence. Nor is it probable that this absorption is confined to the pleochroic haloes.

It is, therefore, doubtful whether there is any considerable excess of radioactive energy available for raising the temperature of the earth.

The zone in which appreciable cooling takes place must extend over only a small fraction of the earth's radius, and the question arises whether the contraction from cooling in this zone is sufficient to account for the folding that we know to have taken place.

Dr. H. Jeffreys estimates that the actual crumpling and overthrusting observed in the principal mountain-chains of the earth has resulted in a decrease in the area of its surface of 2,000,000 square kilometres. At the same time, he calculates that the cooling that is taking place in the earth's interior will, on the basis of the observed coefficient of expansion of the rocks of the earth's crust, result in a decrease in the area of the surface amounting to rather more than 4,000,000 square kilometres.

Now, the folding of the mountain ranges included in this calculation by no means represents the whole of the folding to which the earth's crust has been subjected. Many folded areas are no longer mountainous. They are the sites of ancient ranges which have since been planed down.

It is, therefore, probable that the contraction to which the folds and overthrusts bear witness exceeds that which Dr. Jeffreys believes to have resulted from the cooling of the earth's interior. There is, however, little doubt that far greater contraction has taken place.

The sedimentary and the acid igneous rocks of the continents, which constitute the sial, are apparently underlain, at a depth variously estimated at from 100 to 15 km. by the sima: that is to say, basic and ultrabasic crystalline rocks, or magmas of similar composition, except that they contain water and other volatile constituents.

Dr. Jeffreys bases his calculations of the amount of contraction on the coefficient of expansion of specimens of crystallised rocks which have, of course, lost most of the volatile constituents that they possessed when in the state of uncrystallised magma. Yet, judging from the amounts given off in the course of volcanic eruptions, such as those of Hawaii, volatile substances must form an important proportion of even a basic magma, which will accordingly have a much higher coefficient of expansion than the crystallised rock.

Dr. Jeffreys calculates, however, that the sima is crystalline down to a depth of more than 600 kilometres. This is because he takes the crystallisation point of a basaltic magma under atmospheric pressure at 1200° C. and that of a peridotite at 1400° C. These, however, are the temperatures at which the crystallised rocks that have lost their volatile constituents can be remelted. We know from the observations of T. A. Jagger that the basaltic magma at Kilauea, which retains some, though by no means all, of its volatile constituents, remains fluid at 750° C. It is true that he assumes that the magma was supercooled, but there is no evidence of this. There can be no doubt that the crystallisation point of a basalt- or even a peridotite-magma retaining its volatile constituents would be considerably less than that at which the crystallised rock can be remelted.

It is also assumed by Dr. Jeffreys that the crystallisation point is raised by 3° C. for every additional kilometre of depth, on account of the increase of pressure. This is a fair estimate of the rate of increase of the crystallisation temperature with increase of pressure near the surface; but P. W. Bridgeman has shown that the rate of increase diminishes rapidly as the pressure increases.

---

[1] From the presidential address delivered to the Geological Society of London on February 19, 1926. A large portion of the address in which illustrations are drawn from the Hercynian, Wealden, and Alpine folding, and all references, are here omitted.

Allowing, then, for the fact that the temperature of crystallisation of a basaltic magma at the surface is much less than that assumed by Dr. Jeffreys, and for the lower rate of increase of the temperature of crystallisation with increasing pressures at great depths, there seems every reason to believe that a considerable portion of the cooling zone is in a non-crystalline condition, that it still contains a large proportion of volatile constituents, and that it has therefore presumably a higher coefficient of expansion than solid basalt. Nor would the substitution of a peridotite-magma, which Dr. A. Holmes believes to underlie the basalt-magma at a depth of 45 km., make any important difference.

It must be remembered, however, that, on one hand, the coefficient of expansion of all substances shows a marked increase with increased temperature, and, on the other, it diminishes with increase of pressure.

Unfortunately, we are without precise information as to the physical properties of magmas and still less as to the variations of these properties with changes of temperature and pressure. There is no insuperable obstacle to the determination of these data at temperatures and pressures up to those found at depths of about 35 miles (say, 56 km.), and they may reasonably be extended to considerably greater depths by extrapolation. In the meantime many of the problems that present themselves in geophysical research cannot be solved with any approach to certainty. It is earnestly to be hoped that a serious attempt to obtain the necessary data will be made.

There is another important consideration. In some part at least of the zone of cooling, amorphous magmatic material is passing into the crystalline state, not only as a result of the loss of heat, but also in places on account of the loss of volatile constituents. The process of crystallisation is accompanied by very considerable contraction in the case of all or nearly all silicates and mixtures of silicates, a contraction equivalent to that resulting from cooling through hundreds of degrees, whether in the amorphous or in the crystalline state.

Dr. J. A. Douglas has experimented on the increase in volume when crystalline rocks are melted and allowed to cool rapidly so as to consolidate without crystallising. The following were the results obtained with basic crystalline rocks, the composition of which approximated to that of the sima:

Name and locality of rock	Sp.g. before melting	Sp g of glass	Percentage of defect of volume in the crystalline state compared with that of the glass.
Gabbro (Carrock Fell)	2·940	2·791	5·07
Olivine-dolerite (Clee Hills)	2·889	2·775	3·95
Dolerite (Rowley Rag)	2·800	2·640	5·71
Dolerite (Whin Sill)	2·925	2·800	4·27
Average			4·75

The fourth column must represent the contraction which a glass of the same composition as the rock would undergo in crystallising. This contraction may be compared with that which would have taken place as a result of simple cooling in the crystalline state.

According to Prof. F. D. Adams, the cooling at a depth of 50 km. has been from about 1450° C. to 950° C. If, like Dr. Jeffreys, we adopt Fizeau's formula for the variation of the volume of rocks, with temperature, namely, $V_t = V_0(1 + et + e't^2)$, where V_0 is the volume at 0° C., V_t that at $t°$ C., $e = 7 \times 10^{-6}$, and $e' = 2\cdot4 \times 10^{-8}$, we find that a cubic centimetre of basic rock at 0° C. will have a volume of 1·0606 c.c. at 1450° C., and 1·0283 at 950°. The contraction in cooling from the former to the latter temperature would accordingly amount to 3·05 per cent. of the volume at the higher temperature, about 62 per cent. of the contraction in crystallisation from a melt without volatile constituents. At a depth of 100 km. the cooling is estimated to have been from about 1770° C. to about 1290° C., corresponding to a decrease in volume from 1·08756 c.c. to 1·04897 c.c., a decrease of 3·55 per cent. At 200 km. the cooling is estimated to have been from about 2200° C. to 1900° C. with a decrease from 1·1316 c.c. to 1·0994 c.c., equal to 2·84 per cent. It is evident, therefore, that the contraction on crystallisation would, even apart from the presence of volatile constituents, be much greater than from the simple cooling of crystalline material.

The steam and other volatile substances, however, are eliminated on crystallisation; consequently, the decrease in volume will be far greater than that on crystallisation from a magma without volatile constituents. The volatile constituents may afterwards occupy for a time cavities, large or small, in the consolidated rock or elsewhere in the earth's crust; but by far the greater part will sooner or later escape into the atmosphere, with a corresponding decrease of bulk of the solid earth as a whole.[2] The expulsion of volcanic materials will naturally have a similar effect.

Contraction will also occur on a change of crystalline state from lighter to denser minerals of similar composition, and not improbably on a transformation of elements into others of less atomic volume. Both these changes may be determined by the heavy pressure of the earth's interior. It is, however, probable that most of such possible changes took place early in the world's history. It is only where the pressure has for some special reason been increased or where directed pressure (shearing stress) has intervened, that such changes may be expected to have occurred during the geological time of which we have any record in the rocks.

There is, nevertheless, one change in the terrestrial conditions which will result in a general and progressive increase in pressure, and thus cause an equally general contraction. The acceleration of the moon's position in the heavens is usually considered to be in great part attributable to the slowing down of the earth's rotation. This will result in a decrease in the centrifugal force, with a consequent increase of pressure in the interior of the earth and a corresponding contraction in its volume. These effects have been calculated by R. Stonely, who arrives at the conclusion that "diminishing rotation is a much less potent cause of the elevation of mountain-ranges than is cooling, but that it is sufficiently important to be considered as a large correction to the cooling theory."

---

[2] The latent heat evolved on crystallisation and changes in crystal structure must delay the processes of cooling and crystallisation, while that absorbed on the expansion of volatile constituents will accelerate them.

As I showed in my previous address, there are at least two opposing influences tending to modify the length of the day: the progressive contraction of the earth accelerating the angular velocity, and the tidal friction producing a contrary effect. At present, the latter seems to be more powerful; but it is possible that in the past the reverse has been the case, especially in the early stages of the earth's existence.

All the processes which have been considered will result in direct primary movement downwards towards the centre of the earth; but, on account of the fundamentally homogeneous character of the earth's material at deep levels (shown by the close similarity of the transmission of earthquake waves in different areas), the subsidence from this cause must everywhere be nearly the same, and will rarely result directly in appreciable *differential* vertical movements of the earth's crust.

There are, on the other hand, processes by which the surface of the earth's crust may locally be permanently extended. This can happen in regions of tension in two different ways. In the first place, temporary rifts, often of considerable size, may be filled by igneous magmas which afterwards consolidate, and by broken material from the sides and the neighbourhood. In the next place, movements of extension occur along the planes of normal faults. When, later, a period of compression supervenes, such movements will not be reversed unless the hade, the deviation from the vertical, is very great, that is to say, well over 45°; otherwise, the pressure at right angles to the fault-plane will increase the friction so much that movement will be impossible. The surface of the crust may also be increased by hydration, especially in the case of igneous rocks. These extensions of the earth's crust must in the long run tend to produce effects in the way of folding and thrusting similar to those resulting from the contraction of the interior.

There are other forces operating on the earth's crust, besides those due to the excess of the area of the crust over that of the surface of the interior, that must tend to produce horizontal movements.

In the first place, a slowing-down in the earth's rotation will be accompanied by a consequent change in the form of the solid earth, which on a large scale adjusts itself to the forces operating on it, but of course not so rapidly as do the aqueous and gaseous envelopes, though geologically the time required is relatively short.

Such a reduction of the rate of rotation of the earth will result in a decrease in the equatorial diameter and in an increase in the polar diameter, involving a movement in the substance of the earth. This will consist in a flow, at all levels, from the equatorial plane towards the poles, combined with a slight downward movement near the equator and a slight upward movement near the poles. The circumference at the equator will contract, but one must not expect contraction which is common to the surface and to all depths to have the same effect as a contraction affecting a portion of the interior, and not the exterior; and, as a matter of fact, there are no north-and-south folded mountains that can reasonably be considered to have been formed in this way. The crust at the equator would, therefore, seem not to have been folded from this cause, but to have been distorted horizontally—being contracted east and west, and extended laterally northwards and southwards. This will add to the effect of the simultaneous decrease in the meridional periphery of the earth, and a strong north-and-south compression in intermediate latitudes will result which cannot be relieved by lateral extension, except to some extent in high latitudes where there will be a small but appreciable expansion of the earth's surface.

It is, therefore, not surprising that in low to intermediate latitudes the compressive forces in the earth's crust arising from causes already discussed are intensified in a north-and-south direction so as to favour the formation of east-and-west folding.

Somewhat analogous effects would result from a change in the position of the poles relatively to the configuration of the earth's crust. This would probably be a result of the shifting of the earth's crust relatively to the core, rather than of a change of the axis of rotation of the earth as a whole from one position to another in its mass. Tidal action may result in an east-to-west movement of the earth's crust, but this alone would not directly affect the position of the pole relatively to the features of the earth's surface. But, if there were a locality such as that of a deeply-rooted mountain-mass where the cohesion between the earth's crust and the core was greater than elsewhere, there would be a tendency for the crust to rotate round it, and this would bring new tracts under the poles. There would then be a drifting-away of the continental masses from the new position of the pole on the earth's crust and towards the new position of the equator; this might appreciably affect the configuration of the earth's surface.

It has been suggested that the centre of gravity of the earth's interior does not exactly coincide with its centre of form, so that there is a point on the earth's surface where the force of gravitation is at a maximum, and towards which both the ocean waters and the continental masses tend to move. If this be the case, and the crust of the earth shifts relatively to the interior, the point of maximum gravitation will occupy a new position on the earth's crust, and the drift will be directed towards the latter.

There seems reason to believe that in late Palæozoic times the principal land-masses were united in one great continental mass collected round Africa as a centre, and that they have since drifted away eastwards, southwards, and westwards towards the centre of the Pacific. This would be only what one would expect if the points with the maximum force of gravitation were in Devonian and Carboniferous times in Central Africa, and in Tertiary and Quaternary times in the centre of the Pacific. But, although the forces, developed directly or indirectly as a result of tidal retardation and the resultant relative movement of the earth's interior and crust, must be taken into serious consideration, and may from time to time exercise decisive influence on the structure and configuration of the earth's crust, it is only the horizontal forces resulting from the contraction of the earth's interior, assisted by expansion of its crust in local and temporary regions of tension in the manner already explained, that are sufficiently powerful to account for the development of the folds and thrusts of the present mountain-chains and those that existed in former geological periods.

(*To be continued.*)

Two Oceanographical Expeditions.

I.—THE GERMAN SOUTH ATLANTIC EXPEDITION OF THE *METEOR*.

IN 1919 plans were formulated by the late Dr. Alfred Mertz for a national expedition to study the physical and chemical conditions of the South Atlantic. In conjunction with the Deutsche Seewarte at Hamburg and the Institut für Meereskunde at the University of Berlin, a very thorough programme was drawn up, a scientific staff gathered together, and the use of the gunboat 'C,' renamed *Meteor*, obtained. The vessel is of 1300 tons displacement, having a ship's company numbering 133, which includes the scientific staff of nine, exclusive of assistants, and nine ship's officers, exclusive of engineers and under-officers.

Whereas former oceanographical expeditions have been concerned very largely with the life in the oceans, the programme of this expedition is almost entirely limited to hydrographical and meteorological observations, to be made at numerous positions while crossing the South Atlantic fourteen times between the South American continent and Africa, the various positions being chosen so as to allow of the best use being made of Bjerknes' theory in calculating the currents at various levels and the consequent circulation of the water masses. Particulars of the objects, equipment and first fruits of the cruise, which commenced in January 1924, have been published by Dr. Mertz,[1] and in two later reports by Captain F. Speiss,[2] who succeeded to the leadership of the expedition after the unfortunate death of Dr. Mertz, which occurred shortly after the programme of work was commenced in the South Atlantic.

Fig. 1, taken from Captain Speiss's report, shows the tracks which have been followed and the 139 positions or stations where observations have been made at depths between surface and bottom. Besides these, numerous observations have been made at a number of other positions on the voyage out from Germany. The section from Cape Town to Buenos Aires shown in Fig. 2 indicates the nature and depths of the observations; considered in conjunction with Fig. 1 the intensity of this hydrographic survey is apparent.

With regard to the scope of observations, besides the distribution of temperature and of density, from which the probable circulation of the water in the ocean will be calculated, observations of hydrogen ion concentration, of the oxygen, carbon dioxide, gold, silver, phosphate and nitrate content of the water are provided for, and a method has been devised and used for measuring the rate of evaporation from the surface of the sea. Measurements are made of the waves encountered by a stereophotographic method, and echo-soundings are carried out by three different systems, from the results of which the production of a very complete bathymetric chart will doubtless be possible. Microplankton organisms collected at the various stations are being examined and their quantity measured on board. Regular meteorological observations are made on board and to a height of above 15 kilometres by means of pilot balloons and kites, while at the various ports visited the local geological formation has been investigated.

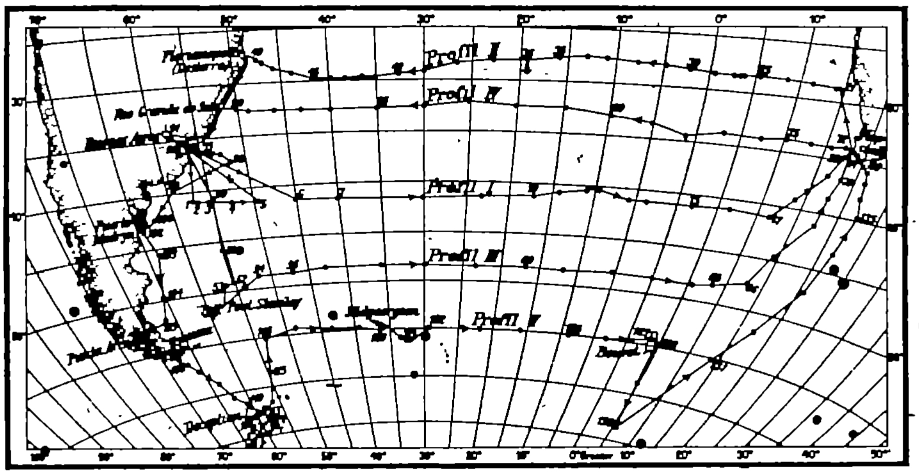

FIG. 1.—Course of the *Meteor*, with the 139 stations where observations between surface and bottom were made.

The reports give particulars of how the work is being carried out and of how it progresses according to the original plan, which the *Meteor* has been able to follow very closely in spite of bad weather experienced in the more southerly latitudes. When the observations are published and the data worked up and charted, they should present a more perfect picture of the observed conditions in this area than we have for any other ocean, and from such a survey there can be little doubt that several general principles will emerge of fundamental importance to the rapidly growing science of physical oceanography.

II.—THE CRUISES OF THE *ARMAUER HANSEN* IN THE EASTERN NORTH ATLANTIC.

For a very considerable time it has been known that the British islands owe their warm climate, in comparison with that of Newfoundland in the same latitude to the Atlantic or European current which bathes our coast, and passes northward, and to the south-westerly winds which produce it. Towards the end of the last century the Scandinavian hydrographers found that the surface temperature of the Norwegian sea varied from year to year largely in relation to the amount of warm Atlantic water which passed into it over the submarine ridge which extends from the Shetlands to Iceland. This variation in temperature in turn affected the climate and several seasonal occurrences along the Norwegian seaboard, such as the annual growth of pine trees, the time of flowering of various plants and probably the seasonal fisheries.

---

[1] "Die Deutsche Atlantische Expedition auf dem Vermessungs- und Forschungsschiff *Meteor*," by Prof. Dr. A. Mertz, *Sitzungsberichte der Preuss. Akad. der Wissenschaften*, 31, 1925.

[2] "Die Deutsche Atlantische Expedition auf dem *Meteor*," *Zeit. der Gesellschaft für Erdkunde zu Berlin*, No. 1 and No. 5/6, Berlin, 1926.

As a natural result, more information was desired concerning the circulation of water in the eastern North Atlantic, and particularly of the fluctuations in the Atlantic current. Owing to the costly nature of investigations over such a wide area, the observations which it has been possible to make have been severely limited; nevertheless, considerable knowledge has been accumulated, notably through the active interest taken by Dr. Nansen. He found water of Mediterranean origin mixed with Atlantic water so far north as Ireland during an expedition made by him in 1910 in the *Frithjof*—a vessel lent for the purpose by the Norwegian Navy. In consequence of this and similar Norwegian and Danish investigations, a new set of questions were raised which made it especially desirable to carry on more extensive studies of the great Atlantic current off Europe.

In a recent publication[3] the scientific results are presented which were made during cruises of the *Armauer Hansen* in 1913, 1914, 1922, 1923 and 1924, extending so far south as Madeira and to Lat. 30° W. some 700 miles to the westward of Ireland. The ship was a small yawl of 56 tons burden, with auxiliary motor only used occasionally; that is to say, she is a vessel smaller than the trading ketches and Thames barges which ply around the British coast. The oceanographical observations were mainly made by Helland-Hansen at numerous stations to depths exceeding 2000 metres. This necessitated manœuvering the ship so that the line along which the instruments are suspended remained in a vertical position throughout the time of observations, even if there is a strong drift caused by wind or current. In this connexion they write: "Care has always been taken to make sure of the vertical position of the sounding line, and the determination of the depths may therefore be considered very trustworthy." No mention is made of the difficulties encountered in carrying out the work from the small vessel during these extensive ocean cruises, but the amount and nature of the scientific data obtained are in themselves a record of the skill, endurance and careful preparation involved. Certainly the cruises were made in summer, but nevertheless this record shows how much can be done with a small sailing vessel suitably equipped.

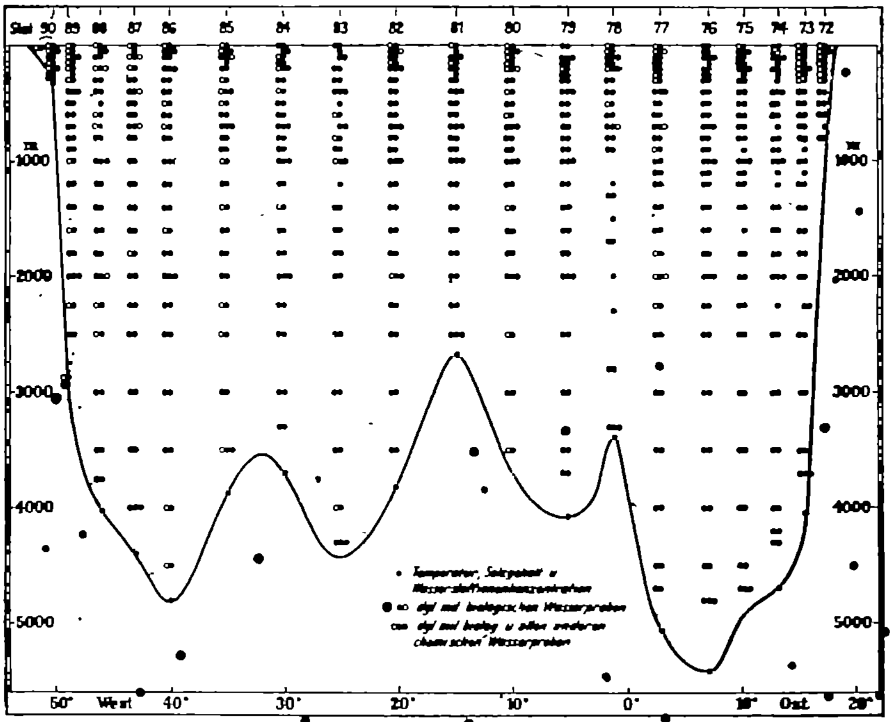

FIG. 2.—Section of the South Atlantic from Cape Town to Buenos Aires obtained from soundings by German South Atlantic Expedition in the *Meteor*.

From the density of the water, the currents were calculated for different water layers by means of Bjerknes' theory and are shown on a number of charts. These show a strong current passing eastward over the submarine bank which extends roughly north and south down the centre of the North Atlantic. This current is in about Lat. 47° N., and on arriving at Long. 25° W., a position roughly five hundred miles north of the Azores, it divides, part turning northward and north-eastward and part turning south to the Azores and Canaries, where it divides again, part turning south and part turning northeastward towards Spain. The currents immediately westward of the continental slope between Ireland and Portugal indicate a number of eddies and a more involved system than that previously supposed; however, the northerly drift of highly saline water welling out of the Mediterranean as a warm undercurrent is shown extending certainly so far as the north of Spain. The existence of these calculated currents at the various depths is based upon the assumption that the movement of water at 2000 metres depth is negligible, for which evidence is presented.

---

[3] "The Eastern North Atlantic." By B. Helland-Hansen and F. Nansen, *Geofysiske Publikasjoner*, vol. 4, No. 2 (Oslo, 1926).

There has been evidence for some time pointing to vertical oscillations of the water layers at a depth of fifty metres or more below the surface in various regions of the Atlantic. This expedition has provided further evidence which indicates that the oscillations may be considerable, particularly in the deeper layers. The oscillations show a more or less regular diurnal or semidiurnal period, which suggests that they are sub-surface waves or undulations having some connexion with tidal phenomena; but how the tidal wave, producing in the open ocean oscillations of less than three feet at the surface, can produce vertical oscillations of the dimensions observed in the lower strata remains inexplicable. The desirability of further knowledge is manifest since a vertical series of observations cannot be expected always to represent the *average* conditions at any particular station; it is therefore of great importance for the discussion of the general conditions of a sea area to study how far the actual observations at the different stations and different depths may be regarded as representative.

During the course of the 1913 cruise some interesting current measurements at various depths were made from a boat moored on the bank around Rockall, an isolated rock some 200 miles north-west of Ireland. At a depth of two metres a rotary tidal stream was found, continuously varying and completely reversing in direction every six hours, a type of tidal streaming which is characteristic of the sea over isolated banks. A limited number of observations at greater depths suggest a similar variation in direction. During the fifth and sixth hours of observation a breeze sprang up and the observations indicated a wind drift of the uppermost water strata superimposed upon the tidal streaming.

Archæology of the Channel Islands.[1]

By Dr. R. R. Marett.

Though there is nothing very new to be said about the archæology of the Channel Islands, some brief notes are here brought together because well-attested facts relating to such an *angulus terrarum* are apt to escape attention. For example, in recent discussions concerning Depéret's proposed method of classifying the subdivisions of the Quaternary, namely, by giving weight primarily and chiefly to the indications afforded by ancient marine shorelines, I have come across no references to the rather striking data of this type provided by the islands (see, for example, my summary account of them in *Archæologia*, 62, 469-80). Thus, one Jersey cave, La Cotte de St. Ouen, exhibits a Mousterian industry with cordiform 'points,' *i.e.* belonging to a phase that is not the latest, as resting more or less directly on a marine deposit of sand and rolled pebbles forming the floor-bed of a cave at about 20 metres above present mean tide-level. On the other hand, another cave in Jersey, La Cotte de St. Brelade, contained the remains of a copious fauna, mammoth, woolly rhinoceros, reindeer, etc., conjoined with the later of two well-represented phases of the Mousterian industry; from which fact it is fairly safe to argue that Jersey was then freely accessible from more spacious lands.

Here, then, is almost crucial evidence that the later Mousterian culture coincided with a period of land elevation preceded by one of subsidence (to use such terms without prejudice to the question whether sea or land was the active factor responsible for the change of level). This would accord well enough with Depéret's Monastirian stage with its 20-metre shoreline marking the downward movement (from the point of view of a man as contrasted with that of a fish) and a later oscillation of at least a like extent in the opposite or upward direction; exactly 20-metres in the way of land elevation being at present necessary to render Jersey accessible from the Continent at low tide. Of previous changes of sea-level it must suffice here to say that at Le Cané de la Rivière, on the north coast of Jersey, there is clear evidence that the sea had time to hollow out a cave at the 10-metre level before it rose to 20 metres and plastered the sides and top of the cave in question with beach-pebbles. Still earlier, one may presume, is a solitary deposit of such pebbles at South Hill at a height of about 45 metres. Unfortunately, these various raised beaches contain no shell whereby to correlate them with Depéret's palæontological series.

When, on the other hand, we turn to post-Mousterian evidence of change of level, a section taken almost anywhere in the valley-bottom on which the town of St. Helier's stands (the level being about 10 metres above O.D.), reveals with remarkable uniformity beneath a few feet of modern alluvium, two peat-beds alternating with two underlying marine layers of sand and shells. In the upper peat-bed a mould for a spear-head has been found, giving it a Bronze Age horizon. From the lower peat have come several rough sherds, one characteristically decorated with punctured dots in rows, that proclaim the horizon Neolithic. Moreover, there can be little doubt that this lower peat-bed is to be correlated with the submerged forest so well in evidence round the islands down to low-tide level and beyond it, as notably at Vazon Bay in Guernsey, whence proof of Neolithic age is also forthcoming. Considerable land-elevation in this region in Neolithic times is thus indicated.

How far these facts have a bearing on the general history of the Channel is hard to say. As for Jersey in particular, its position at the end of a narrow spit of the Continental shelf running westward between depressions hollowed out by ancient rivers would naturally impart to the island a certain tendency to isostatic movement of a more or less local character. Even so its oscillations are so sharply defined, and can be so closely correlated at several points with the archæological series, that they deserve more notice than they have got. If experts from England would face certain other oscillations likely to be encountered on the way across channel, they would be met both with a hearty welcome and with much to puzzle over.

---

[1] Substance of three lectures delivered at the Royal Institution on Nov. 18, 25, and Dec. 2.

As for the Palæolithic record of the islands, nothing of great importance has hitherto come to light apart from the two Mousterian caves already mentioned. The Lower Palæolithic is barely represented by sporadic implements of rather nondescript and doubtful type Rough flints, in which some see signs of human workmanship, have been recovered from the clay capping certain rocks now disjoined from the land; and there can be little doubt that this clay is an æolian deposit of pleistocene age if only because it is distributed impartially between land surfaces of very various elevation. This loess, however, as it may be termed, affords no precise criterion of the age of the associated artefacts (if such they be) since it must have been forming steadily throughout the Ice Age. It is to be noted, by the way, that it extends some way below the present sea-floor, and must therefore have been in part laid down during a time of land-elevation.

Of the Mousterian caves, and more especially of La Cotte de St. Brelade, with its teeth of Neanderthal man, its fauna amounting to nearly forty species, and its flint implements of more than 5000 well-shaped pieces, with as many more showing signs of use, much might be said. Perhaps the most interesting result obtained from the latter site was the clear proof of two occupations separated by a considerable gap of time; a fact which, so far as it goes, would support the Abbé Breuil's recent attempt (*Man*, Oct. 1926) to establish a very long duration for the Mousterian

The Lower Mousterian, associated with an elephant certainly not mammoth and provisionally identified by the late Dr. C. Andrews with *E. trogontherii*, occurred in four feet of indurated breccia, and was characterised by heavy coarse flakes and at least one core-implement. I could not on my own responsibility identify it with the horizon of La Micoque, but should welcome further light on the typological question. Above the breccia occurred a uniform layer, about a foot thick, of fine cave dust, and this bed was quite sterile. Evidently the cave was deserted by man for a very appreciable interval—long enough, in fact, for the fauna to have changed. Above it came six feet of loose rock rubbish, mixed with a light loam, and here occurred a large number of highly finished and beautiful implements of Upper Mousterian type associated with mammoth. The whole was sealed by a thick bed of banded lemming (*Dicrostonyx torquatus*), over which lay 30 feet of sterile clay and rock-rubbish of the type known as 'head.' Finally, the Upper Palæolithic is represented if at all by a well-marked industry occurring in several sites (mostly shallow deposits of peaty soil along the cliffs), which shows a predominance of small blade-like tools, in which a typologist might possibly discover Magdalenian affinities. In association with these has been found a needle which, if made of ivory, as seems to be the case, and not of bone, would decisively fix the horizon as Palæolithic.

Passing on to later times, one may speak comprehensively of the Megalithic period without prejudice to the question whether the monuments with which the islands teem are Neolithic in the sense of belonging to an age when, regionally at all events, polished stone without metal was in use, or are wholly or partly assignable to the Bronze Age. Nay, it may be just worth noticing that one Jersey passage-grave, Mont Ubé, contained specimens of the *pic* and the *tranchet* (figured by me in *Archæologia*, 63, 226), which look like survivals from a previous era, namely, the Campigny period. On the other hand, there are no signs of a local development (such as has been assumed both for the Iberian Peninsula and for Scandinavia) from the true dolmen with a single capstone; but seemingly the full-fledged passage-grave was introduced at the outset. Perhaps the term 'passage-grave' should, however, be reserved for the type of monument consisting in a narrow passage leading into a wider sepulchral chamber, the whole covered by a round tumulus. This, indeed, is the normal structure found in the islands, as also in Brittany and Iberia; but Mr. T. D. Kendrick in "The Axe Age" (Methuen, 1926) has directed attention to two *allées couvertes*, or 'cists,' as he prefers to call them, which he believes to be non-western in character. These are Le Couperon and Ville ès Nouaux in Jersey, both monuments showing the remains of peristaliths which suggest that they were surmounted by long barrows and not by circular mounds.

At Le Couperon occurs a 'port-hole' slab, a fact which affords Mr Kendrick further reason for suggesting eastern influences, proceeding proximately from the Paris basin. In this connexion he likewise points to the complete resemblance between the statue-menhir of the Câtel, Guernsey, with its necklace and closely juxtaposed breasts carved boldly in the round, and certain wall-carvings adorning the cists of the Seine and Oise valleys. Meanwhile, it should be noted that if Ville ès Nouaux be of eastern type as regards structure, it nevertheless contained grave furniture of markedly western pattern such as bell-beakers—a fact chronologically interesting as proving that the cist culture had arrived before the beaker ceased to be in fashion. Further, as regards ceramic, several Jersey passage-graves have yielded a peculiar type of cup-like vessel with a hollow base and characteristic decoration; and some half a dozen more of these in excellent preservation have been found in the newly opened monument of La Hougue Bie. French archæologists have sometimes labelled this type 'supports,' as if other round-bottomed vessels had originally been set up upon them; but it is at least equally likely that they were self-sufficing receptacles of food-offerings to the dead. In any case, more important than the question of their function is that of their bearing on the origins of the megalithic culture-complex as met with in the islands. To judge by the distribution of the very few examples hitherto noticed in France, it would seem that this peculiar ceramic marks the track of a culture coming from east-central France down the Loire valley, probably at some time early in the Bronze Age, and thence turning northwards to Brittany and the islands.

R249

Much might be said about the life of this period as deduced not only from the megaliths but also from humbler remains, such as notably the graves, with the associated cairn and midden of the islet of La Motte, Jersey—to which, by the way, the little island of Thinic, to the west of the peninsula of Quiberon, seems to offer a close parallel (see *Archæologia*, 63, 210).

It must be enough, however, in conclusion to direct attention to two megalithic monuments of special interest. One of these intrigued the dilettanti of the eighteenth century; and Horace Walpole's friend, Marshal Conway, actually removed it in 1787, two years after its discovery in Jersey, to Park Place, Henley, where no British archæologist should fail to pay it a visit. It is in several respects unique among island monuments. For one thing, the covered passage leads into an *enceinte* which is perfectly circular, unlike the normal passage-grave, which is shaped more like a tennis racquet than a jew's-harp. Mr. Reginald Smith (*Proc. Soc. Antiq.*, 1919, 143) compares the shape of a neolithic house with covered passage found at Pléneuf, Côtes-du-Nord. A similar house has recently been discovered at La Sergenté, Jersey. Again, the *enceinte* with its six trilithons, somewhat suggestive of a miniature Stonehenge, may well have been hypæthral as at first designed, though later by design or accident a mound of earth (or blown sand) was superimposed. As for the magnificent passage-grave of La Hougue Bie excavated in 1925, though doubtless its contents were disturbed at some time, it remains in the intact majesty of its structure a very masterpiece of art, unsurpassed whether in size or in the symmetry of its design by any monument of the kind in north-western Europe.[2]

---

[2] On the whole subject see three papers by the lecturer in *Archæologia*, vols. 62, 63, 67, and for full details the *Bulletins de la Société Jersiaise* and *Proceedings of the Guernsey Soc. of Nat. Hist.*, later La Société Guernesiaise.

News and Views.

WITH this issue we begin the publication of a weekly "Calendar of Discovery and Invention," in which, so far as possible, each day will be used to recall some event of importance in the history of science and its application. The notes are being compiled by Engineer Capt. Edgar C. Smith, of the Science Museum, South Kensington, who some years ago contributed to our columns the Calendars of Scientific and Industrial Pioneers. It is not to be expected that every event of importance in the history of science will be referred to; such would be clearly impossible within the limits of a weekly column in a year's issue of NATURE. It is also obvious, from the nature of the records available, that the physical sciences and engineering are likely to figure in the column more than the biological sciences, medicine, and similar subjects, in which it is often difficult to assign the announcement of a discovery to a particular day. Suggestions regarding events suitable for inclusion in the column will be welcomed.

BY invitation of the French Government, a meeting of the executive council of the International Institute of African Languages and Culture was held in Paris on Monday, December 13, instead of in London, as had been previously arranged. It was thus the first to be held outside England, and with it the work of the Institute, which was founded a little over a year ago, may be considered to be fairly launched. The initial difficulty of raising funds, it may be hoped, is well on the way to solution, especially as it was announced at this meeting that the Government of the Gold Coast has promised a donation of £500 a year for the next two years. It is to be hoped that this subsidy will be renewed at the end of that period, and that the example of the Gold Coast will be followed by other African dependencies, as well as by organisations and individuals interested in Africa and African studies. The programme already mapped out by the Institute covers most important fields of research, and its work of co-ordination in the study of African linguistics and ethnology will be especially valuable in promoting the development and education of the African native.

THE meeting was attended by representatives of Great Britain, France, Germany, Austria, and other countries. Among those present were Dr. Westermann, the distinguished German authority on African languages; Sir Frederick Lugard; Major H. Vischer of the British Colonial Office, to whose efforts the foundation of the Institute are largely due; and the Rev. E. W. Smith. Prof. Seligman, who represents the Royal Anthropological Institute in the Institute of African Languages and Culture, was unfortunately unable to attend. M. Labouret of the French Colonial Office was appointed joint Director of the Institute in succession to M. Delafosse, the announcement of whose death was received with much regret. A deputation of the delegates was received by M. Perrier, French Minister for the Colonies, who expressed great interest in the work of the Institute.

AT a meeting of the Newcomen Society on December 15, papers were read on two famous Swedish engineers. The first paper, by Mr. J. G. A. Rhodin, was on Kristofer Polhammer, better known as Polhem, the name he took on being ennobled. Polhem was born in 1661 and died in 1751. Starting as a clerk on an estate, he was enabled to study science at Upsala, and became a mining engineer at Stora Kopparberget, where he built his famous "Machina Nova," a large water-driven headgear for handling the ore. His inventions relating to mining and metal working were numerous. He also made the dock gates for the dry docks at Carlskrona, then the largest in the world, and built the lock at Stockholm uniting the Malar Lake with the Baltic. He also began a system of locks to make the Trolhattan falls passable, but the work was discontinued on account of the death of Charles XII. Mr. Rhodin described Polhem as "one of the first engineers in this world with a thorough theoretical training, yet practical to a degree in spite of his bringing up at *Alma Mater Upsaliensis*."

THE second paper read before the Newcomen Society on December 15 was the outcome of a translation of the book by Triewald on the "Fire and Air Machine at Dannemora," undertaken by Mr. Are Waerland for the Newcomen Society. Triewald lived in England about ten years, was familiar with Newcomen, erected a Newcomen engine near Newcastle, and built the first steam-engine used in Sweden. His book contains the first complete description of the atmospheric engine of Newcomen, and is therefore of special interest to the Society. It is hoped to publish the English translation. Like many men of his time, Martin Triewald wrote on a great variety of subjects. Born in 1691, he early engaged in business, but becoming bankrupt, at the age of twenty-five years he came to England. He was befriended by the Dutch Minister and attended the lectures of Desagulier, became known to Newton, and then found employment with Ridley of Newcastle as an engineer. At the age of thirty-five years he returned to Sweden and at Dannemora built his great engine. He afterwards held various Government appointments, was the first to introduce the experimental methods of science into Sweden, and was one of the six founders of the Royal Swedish Academy of Sciences. He died in 1747. At the University of Lund is a fine collection of scientific apparatus collected by Triewald and used by him for his lectures.

To the panoramas illustrating various parts of the British Empire, several of which were brought to the Imperial Institute from the Wembley Exhibition, the Director, Sir William Furse, has recently added two. One, in the Falkland Islands Court, represents a whale, off the coast of South Georgia, being harpooned by a 'chaser' fitted with a modern harpoon gun. The mother ship, where the carcase will be cut up, is not shown in the picture. The sea is cleverly modelled and looks well from a distance, but on a nearer view betrays its plaster composition too obviously. It is a question whether the visitor should not be prevented from coming too close. In this, as in the previous models, the horizontal plane is tilted up, like the stage of a theatre, so that the line of sight approaches it at a greater angle than natural conditions usually permit. The evident advantage would be attained in a less forced and less perplexing manner if the models were placed a little lower.

THE other model referred to above depicts wild animal life in Tanganyika. The twin peaks of Kilimanjaro rise in the distance, while over a richly diversified foreground are scattered various members of the fauna, from monkeys and lions down to crocodiles and snakes. The exhibit is designed and executed by D. Y. R. Furse and R. T. Roussel for McCorquodale and Co., and we are told that most of the animals have been modelled by an artist who has almost daily acquaintance with them on his farm in East Africa. Even he, however, can scarcely have seen all these creatures at once. This familiar defect of such panoramas is to some extent remedied by the large extent of country shown in a width of about six feet and the small scale of the animal models. These in themselves are characteristic enough, but the same can scarcely be said of the flora. All the trees and shrubs are made of a curious material which looks like the skeleton of some antipatharian or gorgonid coral. If this really is the case, we may at least suggest that the needed variety might have been attained by using more than one species. The Director's attempts to interest the public by these models are heartily to be commended, but one has to guard against giving false impressions.

THE Institution of Chemical Engineers held a very successful conference on December 8-10 in the Science Museum, South Kensington, the subjects discussed including the measurement of mechanical power absorbed by driven machines, the uses and limitations of statistics in industry, air elutriation, and refrigeration. Although a few of the papers could be classed as specifically chemical, most of them introduced chemical subject matter by way of illustration. The practice of holding conferences at which a number of papers are read, appears to be growing in Great Britain. Multiple programmes have the advantage of making it worth while for country members to travel long distances, so that meetings are larger and colleagues are more certain of seeing one another. Secretarial work is also more concentrated and therefore more economical. On the other hand, papers are apt to crowd one another out, and discussions are thereby curtailed.

MESSRS. R. G. Parker and D. N. Jackman described a new form of recording torsion-dynamometer of the type that does not itself convey power, but is applied to a transmitting shaft. Such a shaft is very slightly twisted, and the twist, which is proportional to the power, is measured, the readings being recorded photographically. In a symposium on statistical methods in relation to industrial efficiency, Messrs. D. Ryder and T. C. Finlayson dealt with the control of chemical-plant operation by this method, mainly from the point of view of the works manager. The points discussed included the transference of material, production, reports by shift foremen, the plant manager, the engineer, and the laboratory; also the methods used by the statistical office in summarising the data concerning production, labour, and stocks. In his paper on some uses and limitations of statistics in industry, Mr. H. C. Marris deplored the paucity of statistical material for forecasting short-term trade movements.

ON the third day of the conference, Dr. Geoffrey Martin contributed a paper on the laws of air elutriation, pointing out that Stokes's law applies only for very small particles, and advancing other generalisations for particles of larger size. He emphasised the influence of temperature on particle size, and expressed the view that there is great scope for research on the influence of particle-shape on lifting power. The concluding paper, on refrigeration in the chemical industry, by Mr. H. M. Dunkerley, contained many details concerning the construction of refrigerating plant and useful data on costs of the process. As the result of the study of a large number of installations of different types, he concludes that their capital cost ranges from £70 per 10,000 B.T.U. per hour for plants with a capacity of 250,000 B.T.U. per hour, to £50 for plants with a capacity of 2-3 million B.T.U. per hour.

FURTHER official information on "The Wet November of 1926" is given in the *Meteorological Magazine* for December. The total for the month was above the average everywhere over the British Isles except along the north-west, north, and north-east coasts of Scotland. The excesses were largest in the south-west of England and Wales and in Connemara. More than twice the average was recorded in these areas as well as at Wetherby in Yorkshire and at Dundee. Falls of more than 250 per cent. of the average occurred in parts of Dorset, Hampshire, and Hereford, while at Ross the fall of 7·87 in. was so much as 311 per cent. of the average. The largest monthly totals were those reported from Llyn Llydaw on Snowdon of 19·50 in., and from Delphi in Connemara of 18·50 in. More than 5 in. of rain was recorded in one day, in Snowdonia on November 4 and in Connemara on November 18. At Camden Square the number of days of rain, 25, and the duration of rainfall, 85 hours, were the largest in November since records commenced, in 1858 and 1881 respectively. It was the wettest November over the British Isles as a whole.

IN order to illustrate some of the recent advances that have been achieved in British-made microscope object-glasses, Messrs. R. and J. Beck, Ltd., of 69 Mortimer Street, London, W.1, recently gave a demonstration of the results obtainable from apochromatic object-glasses of their own manufacture. During the past five years these lenses have been completely redesigned, and a method of testing by zones to the extreme margin has been introduced, with the result that the resolving power of the lenses attains the theoretical limit for their respective apertures. The specimens exhibited included a ⅔-in. apochromat, 0·35 n.a., resolving the dots in *Pleurosigma formosum* (dot interspaces about 36,000 per in.); a ¼-in. apochromat showing resolution in dots in *Navicula rhomboides* (about 66,000 lines per inch); the resolution in dots of the *Amphipleura lindheimerii*, *styrax* (about 90,000 per inch), by a ⅙-in. apochromat, 0·95 n.a., the theoretical resolving power being about 95,000 lines per inch; and the resolution of dots in *Amphipleura pellucida* (about 130,000 per inch) by a $\frac{1}{12}$-in. oil-immersion apochromat, 1·4 n.a., with a theoretical resolving power of about 140,000 lines per inch. Demonstrations were also given of methods of testing the general quality of an object-glass. These included the use of a podura scale, which is a good test of the central zones of a high-power object-glass, and of a silver film with pinholes, which provides also a sensitive method of adjusting the tube length to suit the objective. In the series of experiments dealing with illumination, the most interesting was one showing a portion of a diatom overhanging the strip on which it was mounted. While the image of the portion supported and covered by glass was obliterated by glare caused by multiple reflections from the glass surfaces, there was good resolution and complete absence of glare where there was no cover glass or slip.

THE Wellcome Bureau of Scientific Research and Museum of Medical Science, situated at 25-28 Endsleigh Gardens, London, have recently been enlarged, and we received, on the occasion of their reopening by the Minister of Health, a profusely illustrated booklet giving an account of the work of the Bureau and its affiliated institutions, the Entomological Field Laboratory and the Physiological and Chemical Research Laboratories, together with a description of the contents of the Museum. There are also included lists of the papers published from the Bureau and the research laboratories from their foundation to the present time. The Museum of Medical Science is arranged to afford a continuous demonstration of various diseases, their causes, effects, and treatment, so as to give a graphic picture of the more important features. On the ground floor are arranged exhibits of the diseases caused by the Metazoa, venomous beasts, insects, worms, etc. The first floor is devoted to diseases caused by protozoa and spirochætes, and a special section is given to leprosy and tuberculosis. The second floor has as its exhibit the diseases caused by bacteria, including the exanthemata, whilst the third floor demonstrates dietetic, metabolic, and blood diseases, a section being also given to new growths. The Bureau does no routine teaching, but is open to individual workers who wish to follow some particular line of investigation. The Museum is open to all medical men, health officers and students, and is available to teachers of medicine for the purpose of giving demonstrations to their classes.

WE learn from the *Bell Laboratories Record* that the John Scott medal, founded in 1816 by John Scott of Edinburgh and awarded from time to time by the Board of City Trusts of Philadelphia for outstanding inventions, has been awarded to Gustaf Waldemar Elmen for his invention of permalloy. This nickel-iron alloy, which is noteworthy for its high permeability for minute magnetising force, is widely used in transformer cores, certain telephone receivers, and in 'loading' submarine telegraph cables for high-speed transmission.

SHORTLY after the s.s. *William Scoresby* sailed from Hull to join the *Discovery*, the house magazine of Messrs. Reckitt and Sons published an account of those celebrated whalers and explorers, the Scoresbys. It was illustrated from one of the original log-books and other material in the Fisheries Museum at Hull, and Mr. Sheppard has now included it in the 'Record of Additions' to the Hull Museum, No. 69.

THE late Prof. R. Klebs, of Konigsberg, who was the most distinguished student of the insects included in Baltic amber, himself formed a large collection of such objects. A large number of his specimens was purchased by the Trustees of the British Museum in

1892 to enrich the extensive national collection of *inclusa*; but he left to his heirs a still larger collection containing many specimens of historic importance. We are glad to learn that this collection has not been dispersed, but that it has been found possible to purchase it for the Geological Institute of the University of Konigsberg, which already possesses a famous cabinet of these objects. Properly qualified research workers will now, as in the past, be accorded the utmost facilities for the study of these great collections.

MESSRS. Harold C. Urey and Arthur E. Ruark, writing from the Johns Hopkins University, Baltimore, Maryland, state that they are preparing a book of about 700 pages on atomic and molecular structure, embracing both the theoretical and experimental aspects of the subject, and that they will be glad to receive reprints of private communications as to results not yet published.

MESSRS. C. Baker, 244 High Holborn, London, W.C.1, have prepared a new issue (No. 88) of their Classified List of Second-Hand Scientific Instruments. The catalogue is divided into sections dealing with microscope apparatus, surveying, astronomical and other instruments, spectroscopes, physical apparatus, and so on. The present list contains offers of a number of students' microscopes and accessories, while the astronomical telescope section is also large and its contents varied. Among the larger instruments is an 8-in. Cooke equatorial which was the property of the late Dr. W. H. Maw. Surveying instruments, and field glasses and small telescopes are let out on hire. Nine volumes of NATURE (1885–1890) are also offered for sale.

MR. GEORGE C. SHERRIN has designed, and Messrs. George Philip and Son, Ltd., have produced, a set of apparatus for demonstrating popular experiments in dynamics (20*s*. net). The set is supplied in a wooden box and is accompanied by an illustrated handbook. The apparatus consists of nothing more than a series of small steel rods of varying thickness, of weights, pivots, and collars, the parts being assembled in much the same way as the parts of a 'meccano' outfit. The result is to produce a toy capable of demonstrating—and that very effectively—the relative movements of earth, moon, and sun, the action of centrifugal force, various gyroscopic effects, and the principle of Foucault's pendulum. In itself, this is no mean achievement for such a simple toy, but in reality its 'star' turn is intended to show the action of the Flettner rotary cylinder. If a criticism might be levelled against such a delightful toy for grown-ups, it is that the last demonstration fails to carry complete conviction, first because an artificial wind created by blowing from the mouth cannot be relied on to strike a moving rotating cylinder accurately in a specified direction, and secondly, the deviations from accuracy in this respect may themselves produce the actual effects to be observed. If the toy is to rank as a piece of scientific apparatus, certain of the parts will require to be more delicately made.

Our Astronomical Column.

OBSERVATIONS OF PROXIMA.—Union Observatory Circular, No. 70, contains some interesting notes on this star by Mr. Innes and Dr. van den Bos. The colour is orange or orange-red, the spectrum probably *K*, the visual magnitude 11·2, the photographic 13·0. The parallax is given as 0″·90, which is larger than that deduced from the assumption that parallaxes and proper motions are proportional when compared with α-Centauri. Dr. van den Bos makes the interesting, but rather improbable, suggestion that the sun, Proxima, and α-Centauri form a straight-line solution of the three body problem. The parallax of the centre of gravity of the system would be 1″·14. It is satisfactory that Dr. Alden will investigate the parallax of Proxima with the Yale Telescope at Johannesburg.

THE SOLAR PHYSICS OBSERVATORY, CAMBRIDGE.—The thirteenth annual report of the Director of the Solar Physics Observatory, Cambridge, has recently been received, describing the stellar and solar work carried out at the observatory during the preceding year. Amongst the published work on stellar spectroscopy, mention may be made of a paper by Mr. Baxandall on absorption lines in spectra of types *G*, *K*, and *M*. The wave-lengths, intensities, and probable origins of lines in typical spectra of these classes have been determined and compared, in order to investigate the nature of the changes that occur in this region of the stellar sequence. Preliminary experimental work is being done by Mr. Carroll on the photography of the extreme red region by means of hypersensitised panchromatic plates, and also in testing the theoretical effect of stellar rotation upon absorption lines by studying the same effect in the solar spectrum. In the department of solar physics, an important piece of work (begun in 1916) has now been completed by Mr. Baxandall in revising the chemical origins of Fraunhofer lines in Rowland's tables. This work has been completed for the region λλ3900-5900, and the results sent to Mount Wilson for incorporation in a revision of Rowland's tables by the International Astronomical Union. Spectroheliograms of the sun's disc have been obtained on 118 days, and these, augmented by 326 spectroheliograms from Kodaikanal, have been studied by Mr. Butler. An investigation by the Director, assisted by Mrs. Beech, on the distribution of outbursts of sunspots, now covers four complete 11-year cycles, and a summary of the results is being prepared.

THE DISTANT COMPANION OF CASTOR.—An interesting article in the *Scientific American* (December) by Prof. H. N. Russell, describes recent researches on this star. A few years ago Messrs. Adams and Joy at Mt. Wilson found that it is a spectroscopic binary (as are the bright components of Castor) with a period of 19 hours 32 minutes. Dr. van Gent, of Leyden, finds that partial eclipses of each component by the other occur at intervals of 9^h 46^m. Their distance apart is 1,600,000 miles, and each is 520,000 miles in diameter. The mass of each is 0·52 sun, and the density 2·5 sun, or 3·5 water. It is the greatest density found for a spectroscopic binary. The total light of each is $\frac{1}{30}$ of the sun's, and the surface brightness $\frac{1}{11}$ of the sun's. The concluded surface temperature is 3500° C., in good accord with the *M* type of spectrum which was found for them. It is of great interest and importance to have these accurate details of a pair of typical dwarf stars.

Research Items.

West Indian Stone Collars.—An interesting suggestion relating to the origin of the 'stone-collars,' which are a problem in West Indian archæology, is made by Mr. A. D. Russell in *Man* for December. The collar stone is an object in shape much like a horse collar, but obviously too small for that purpose, and unsymmetrical in shape, being bent to one side at the narrower end. Various theories as to their origin have been put forward. Mr. T. A. Joyce has suggested that a wooden mechanism is indicated, two unequal ends of the fork of a tree being bent round and fastened together, the part of the tree cut off below the fork being represented by the protuberance called by some archæologists the 'shoulder.' It is here suggested that this wooden mechanism was a tree climber, which is symbolised by the stone collar. This might more accurately be termed a belt or cincture. The palm climber of West Africa and the West Indies, with which the collar is compared, is made in two pieces. Two lengths of supple wood are bent into a long oval hoop, the two ends on the right side being secured by a permanent fastening, those on the left being done up and undone as need requires. The identity of the palm climber in West Africa and the West Indies is scarcely to be explained as introduced by the slave trade, since the archaic stone collar proves its existence in the latter area before slaves were introduced.

Mohammedan Child-killing Demons.—In *Man* for November, Mr. W. Ivanow points out that Persia has preserved under a Mohammedan cloak many customs and beliefs descended from a remote antiquity. A great deal of this material is to be found in the literature and, especially, in manuscripts. In support of this, extracts are given from a rare medical treatise, written at Delhi in 1876, which reveals some peculiar beliefs relating to the supernatural malevolent beings causing death or harm to young children. The work is called "The Comfort of Man," the author being Abdu'l-Qawi ibn Shihábi'd-din, surnamed Ziya. All evil beings are divided into five classes. The vampires attacking children belong to the fifth class of *divs* and *peris*. Of these there are two divisions, shapeshifters or were-hyænas (*Kaftár*) and Ummu's-sibyan, called in Arabic "the mother of children," probably an ancient conception of the spirit causing the premature death of new-born babes: apparently Lilith, the Lamia, or the Strigil. According to Ziya she is the mother of devils and has seventy-five baby-*divs* at her breast. When a woman gives birth she may, if not watched, substitute a *div* for the human child. Burnt hair from the back of a black cat will drive her away. The *Kaftár* or hyæna, a rare animal in Persia, seems to imply a witch, but it has not much connexion with lycanthropic ideas. References to it are rare in Persian literature, and it is doubtful if the belief survives among the people to-day, unless it is under another name.

Spermatogenesis in the Mouse and the Rabbit.—K. Masui (*Jour. Coll. Agr.*, Imp. Univ. Tokyo, 8, No. 2, 1923, just received) undertook a reinvestigation of the spermatogenesis of the mouse and of the rabbit, chiefly with the purpose of studying the chromosomes. Measurements of the spermatogonial chromosomes show that these are in pairs and that there is a constant relation between their size and their form. Two special chromosomes are probably the sex chromosomes. The observed variation (44 to 54) in the number of chromosomes in the rabbit is attributed to the fragmentation of certain chromosomes caused by the fixation. The diploid number in the mouse is 40. The conjugation of the chromosomes probably takes place by telosynapsis in the mouse and by parasynapsis in the rabbit. From the behaviour of the sex chromosomes it is suggested that dimorphism of the sperm results. The mitochondrial granules do not originate from the nucleus in the early stages of the spermatocyte, but exist in the cytoplasm from the beginning.

Phylogeny and Classification.—In an extended discussion of phylogeny and the natural system, Dr. W. B. Crow (*Jour. of Genetics*, vol. 17, No. 2) reviews the various conceptions of phylogeny and their relation to classification. He covers a wide field of reference with relation to plants and animals, but occasionally betrays an inadequate first-hand acquaintance with the various interpretations placed upon the variations he is discussing. His paper serves, nevertheless, to focus attention afresh upon phylogenetic problems. He points out the inadequacy of causal morphology without an historical background to explain the problems of relationships, and shows, *e.g.*, that there are good reasons for concluding that such a simple colonial form as Pleurococcus has been derived by reduction from filamentous ancestors. He emphasises the principle of Cope, that in tracing the descent of genera, purely specific characters should not be taken into account, and similarly concludes that, in tracing the phylogeny of species, no account should be taken of the genealogy of individuals. This leads to a discussion of Mendelism from a phylogenetic point of view, and the recognition that the genealogy of gametes has its bearing on the phylogeny of characters.

Tertiary Shells from Japan.—A number of fossil mollusca and brachiopoda from beds in the island of Sado, off the coast of Echigo, Japan, have been described by Prof. Matajiro Yokoyama (*Jour. Fac. Sci.*, Imp. Univ. Tokyo, Sect. 11, Geol., etc., vol. 1). These fossils come from the Sawané formation, and the author concludes that their geological horizon corresponds to the Musashino (Pliocene) of the neighbourhood of Tokyo. Following the few "general remarks" and table of distribution, the paper consists of descriptions of 149 species of mollusca and brachiopoda, including a goodly number believed to be new and figured on the six accompanying plates. There is also a good index.

Marine Shells of the W. Coast of N. America.—The first volume of what promises to be a most important manual on "The Marine Shells of the West Coast of North America" (*i.e.* Canada and the United States, but not Mexico), dated 1924, has only just reached us. It is published by the Stanford University and in somewhat Gilbertian manner forms No. 1, vol. 1, of the "Geological Sciences" series, and has been compiled by Mrs. Ida S. Oldroyd, the Curator of the Geological Museum. When completed the work will cover in extended form the same ground occupied by the 'Summary' by Dr. Dall, issued in 1921 (*U.S. Nat. Mus. Bulletin*, 112) with the addition of the Brachiopoda. The classification followed, though not so stated, is that of the same veteran conchologist, first proposed in 1895 (*Trans. Wagner Free Instit.*, vol. 3, No. 3). The major divisions above genera are not defined, but each genus is, while with each species is given the original reference and description, supplemented where necessary from other sources, followed by the citation of the type and type locality, with its 'distribution' (or 'range' as alternative term) and 'range in time.'

It is stated that some new species described by Dr. Bartsch are included, but apparently not in the present volume, which deals only with the Pelecypoda and Brachiopoda. To the 247 pages of text there are appended 57 plates of unequal merit that do not proportionately enhance the value of the volume, while the individual members of a genus, instead of being figured together, are peppered indiscriminately among the plates, sometimes widely apart. The task of bringing together this mass of material must have been enormous, and Mrs. Oldroyd will receive the cordial thanks of all fellow-workers, who will impatiently await the issue of the further volumes.

ISOSTASY IN SPAIN.—A recent report on the isostatic reduction of gravity stations in Spain (*Mem. del Inst. Geog. y Cadastral*, Madrid, vol. 15, 1926) is summarised and commented upon by W. Bowie in the *Am. Jour. Sci.* for October 1926. The computations were made by the U.S. Coast and Geodetic Survey. The method of least squares shows that the most probable depth of compensation is 96 km. as in the United States. The average anomalies are + 0·011 with regard to sign and 0·032 without regard to sign, the corresponding United States figures being - 0·006 and 0·021 respectively. It is noteworthy, in looking for an explanation of the residual anomalies, that the Spanish stations on pre-Cambrian formations give an average anomaly of + 0·047, while those on Tertiary formations give - 0·033. Anomalies have also been computed for depths of compensation ranging from 56·9 km. to 184·6 km. Very little difference was revealed by the results, except for the greater depths where the larger anomalies became exaggerated and nearly all became positive. The recent tendency towards adopting a smaller depth of compensation than those formerly advocated thus receives support.

ISOLATION OF ELEMENT 61.—Since the appearance of a preliminary note on the independent isolation by Rolla and Fernandes of element 61, mentioned in NATURE, December 4, 1926, p. 820, we have received a fuller account of their investigation in the September issue of the *Gazzetta Chimica Italiana*. The paper contains diagrams of spectra and a chart illustrating the long series of fractional crystallisations to which the didymium earth was submitted. Among the peculiarities displayed by the absorption spectra of the extreme fractions may be mentioned the strong absorption bands in the yellow, attributed up to now to neodymium, which by dilution of the solution are divided up into numerous lines having for the various fractions very diverse relative intensities. The peculiarities of these fractions are identical with those which are attributed to the presence of element 61.

PROPERTIES OF ACETONE.—Some accurate values for the vapour pressures and densities of acetone from about - 80° to + 60° appear in the *Journal of the American Chemical Society* for November. These are intended to replace the existing data, among which considerable discordance is noted. The determinations were carried out by Felsing and Durban in calibrated apparatus to which the acetone, purified and dried by distillation and by crystallisation as the acetone-sodium iodide addition compound, was transferred by direct vacuum distillation. The measurements were carried out in two types of cryostat, one containing liquid paraffin and kerosene for temperatures above 0°, and the other containing ethyl bromide for the lower temperatures. The solubility of carbon dioxide in acetone was also determined over the range - 75° to + 20°, and the latent heats of evaporation at different temperatures were calculated from the vapour pressure data by means of the Clausius-Clapeyron equation.

LOW-TEMPERATURE CARBONISATION RETORT.—In pursuance of a policy of the Department of Scientific and Industrial Research adopted in 1924 (NATURE, September 20, 1924, p. 441), the Director of the Fuel Research Board has issued a report (H.M. Stationery Office, 9d. net) on a test on a 'Fusion' rotary retort for the carbonisation of fuels at low temperatures. The retort, installed at the works of Electro-Bleach and By-Products, Ltd., Cledford, consists of a horizontal externally heated rotary cylindrical retort, through which the material passes while stirred and kept from lodging on the walls by a special type of 'breaker.' The retort was rated to treat 5 tons per day, but in the test 3·4 tons of Welbeck Cannel was put through. 50 gallons of tar and oil was collected per ton, and it was shown that the recovery might have been increased to 54 gallons. 2740 cub. ft. of gas of calorific value 1070 B.T.U. per cub. ft. (gross) was obtained. No operating difficulties of any great consequence were noted. The test showed that a good yield of liquid products was obtained, but the solid product was in a finely divided form as a result of the action of the breaker and probably suitable for pulverised fuel firing. This may be satisfactory when dealing with a non-caking low-grade fuel, such as was used here. It restricts the scope of the process, which scarcely seems adapted to produce a smokeless domestic fuel.

THE SHOCK-WAVE FOLLOWING DETONATION OF HIGH EXPLOSIVES.—What is the nature of the 'shock-wave' sent out by the detonation of a high explosive? How far and at what speed does it travel? How is it that the flame from a high explosive may apparently penetrate a region occupied by an explosive gas mixture without igniting it? These are some of the problems raised by the use of high explosives in fiery mines, and they are problems which have not yet received authoritative answers. Indeed, it may be said that, until the recent work inaugurated by Prof. R. V. Wheeler, of the Safety in Mines Research Board, the functions of the shock-wave have not been so fully studied in England as they have been abroad, especially in France, where *l'onde du choc* has received both theoretical and practical investigation. The Mines Department has now issued a paper (No. 29) forming Part 2 of the research "On the Pressure-wave sent out by an Explosive," by W. Payman and W. C. F. Shepherd, assistants at the Mines Experimental Station. An apparatus has been constructed whereby the flame issuing from a high explosive has been directly photographed on a moving film, which at the same time registers the passage of the preceding shock-wave by *Schlieren* photography and also the movements of the products of combustion, since these were found to be opaque to the arc-light which gave the *Schlieren* effect with the pressure wave. It was thus possible to measure the speed of the shock-wave sent through the air by the explosion of a No. 6 Detonator, and its gradual slowing down as it travelled away from the experimental tube. The expanding products of combustion closely follow the shock-wave from the mouth of the tube, but soon begin to fall behind it. Behind the products of combustion the visible flame issues from the tube, and never gets in front of the products. This explains why a No. 6 Detonator will not ignite firedamp mixtures, since the inflammable gas would be shielded from the flame by an extinctive blanket of burnt products. The speed of the shock-wave as it starts through the open air was found to be roughly twice the velocity of sound.

Perth Meeting of the Australasian Association for the Advancement of Science.

THE eighteenth meeting of the Australasian Association for the Advancement of Science was held in Perth during the week commencing on Monday, August 23, but was extended in the form of excursions well into September. As this was the first time the Association had consented to visit Western Australia, special efforts were made to induce members from the other Australian States and New Zealand to attend the meeting. The State Government of Western Australia granted £1,200 for printing and publishing, and offered free transit over the State railways to all visiting members; and the Australian Commonwealth Government was induced for the first time to contribute towards the general expenses of the meeting the sum of £750, out of which travelling allowances were paid to members of known scientific standing who came to Perth over the Transcontinental Railway. Furthermore, private hospitality during the meeting was arranged in Perth for all members from other States who would accept it, and on most of the excursions members were carried free.

In response to the invitation more than 200 members from the other Australian States and New Zealand attended the meeting. To transport this number in addition to the ordinary traffic an average distance of more than two thousand miles each way taxed the resources of the Transcontinental Railway, but the task was satisfactorily accomplished. About half the visitors, including most of the principal officers of the Association, were carried in a special train, thus making the overland journey an excursion in itself. The total enrolment for the Perth meeting included about 750 members and more than 200 associates. Among the visiting members were delegates from some fifty scientific, technical, and educational bodies in the other States, and delegates from the Commonwealth Government and the Governments of New Zealand, New South Wales, and South Australia. More than twenty scientific and other bodies in Western Australia also sent delegates to the meeting.

At noon on Monday, August 23, the Mayor of Perth gave a civic reception to the Association in the Perth Town Hall. In the afternoon Mr. G. A. Julius, chairman of the reconstituted Council for Scientific and Industrial Research, addressed the Association on the organisation and aims of that body, and explained the important influence its activities must have on the future development of pure and applied science in Australia. In the evening the incoming president, Prof. Edward H. Rennie, delivered his inaugural address in the Perth Town Hall on "The Chemical Exploitation, Past, Present, and Future, of Australian Plants." The retiring president, Lieut.-General Sir John Monash, presided, and at the close of the address a cordial vote of thanks was proposed by the Governor of Western Australia (Sir William R. Campion) and seconded by the Mayor of Perth. On Thursday, August 26, the University of Western Australia gave a garden-party in its new grounds at Crawley. Three meetings of the General Council were held during the week, the most important business done being to adopt a new constitution for the Association and to advance the Subsection of Pharmacy to be a full Section to be designated "Section O." Sectional business extended from Tuesday, August 24, to Friday, August 27, inclusive, meetings being held in the daytime in the Perth Modern School and in the evening in the temporary buildings of the University. At the end of the week most of the visitors left to take part in various long-distance excursions.

An innovation tried in some of the sections at the Perth meeting was to hold evening sessions for papers and discussions on topics of more general interest, including in a few cases the sectional presidential address. This was to enable local business and professional men to take part who could not have attended in the daytime, thus extending the opportunities of the general public to share in the activities of the Association. The innovation was fully justified by results, and will probably be taken as a precedent at future meetings.

In his inaugural presidential address, Prof. Rennie, after an appreciative reference to the late J. H. Maiden, for many years general secretary of the Association, and Mr. F. G. Smith, well known for his work on the eucalyptus oils, gave a brief summary of recent work on the structure of the atom, the discovery of new elements, the possibility of atomic transformation, and the significance of the penetrating radiation discovered by Millikan. The main part of the address dealt, however, as its title implies, with the constituents and economic possibilities of Australian plant products, much of it describing Prof. Rennie's own work of the past forty years. The chief plant constituents and products considered were essential oils (eucalyptus, sandalwood, boronia, etc.), gums and resins, coloring matters, and the poisons which cause so much loss to stock owners and farmers. Prof. Rennie strongly urged the need in all the Australian States for active reafforestation to maintain a supply of raw materials, and for research on new products and on methods of utilising the present great waste from timber mills.

At the conclusion of his address, the president presented the Mueller medal of the Association to Prof. F. Wood Jones, for distinguished work in anthropology.

In Section A (Astronomy, Mathematics, and Physics) Prof. Kerr Grant gave the presidential address on "Atomic Transmutation." He showed that the developments in physics during the past twenty-five years are based chiefly on the theory of relativity, the quantum theory and the theory of the nucleus atom. The various attempts that have been made to bring about transmutation were reviewed and discussed, and the conclusion was drawn that transmutation of the heavier elements by artificial means, although not improbable, has not adequately been proved.

In his presidential address to Section B (Chemistry) on "Some Aspects of the Problem of Molecular Structure," Prof. James Kenner reviewed the chemical and physical data at present available for developing a rational theory of molecular structure. Such a theory must account for the intricate structure of carbon compounds as well as for absorption, catalysis, and molecular association, the last being specially important since substances like the proteins and rubber have been shown to be associations of relatively simple molecules. Prof. Kenner believes that a firm basis for such a theory and the means to develop it are already at hand. This address followed that in Section A, the two addresses in fact being the first items in a joint discussion of the two Sections on "The Atom and Valency."

In Subsection B (Pharmacy) Mr. A. T. S. Sissons gave the presidential address on "The Indebtedness of Pharmacy to Organic Chemistry," summarising the achievements of organic chemistry in purifying and standardising naturally occurring drugs, and in synthesising these together with many others not found in Nature.

In Section C (Geology and Mineralogy) Sir Douglas Mawson, president of the Section, gave an address on "The Igneous Rocks of South Australia—a Brief Survey of Present Knowledge Relating Thereto." Igneous activity in South Australia appears to have been restricted to four periods: the older pre-Cambrian, as seen at Port Lincoln and Carrow; middle pre-Cambrian, shown by uncrushed granites in the Eyre Peninsula; late pre-Cambrian, as in parts of the Mt. Lofty Ranges; and Tertiary, as in the effusions in the Mt. Gambier district and on Kangaroo Island.

Prof. Launcelot Harrison, president of Section D (Zoology) gave an address on "The Composition and Origins of the Australian Fauna, with special reference to the Wegener Hypothesis" The Australian fauna seems to have had three main origins: an Autochthonian, established in the south-west in very early times; a Euriotian, probably derived by way of the Antarctic continent in Mesozoic or Miocene times; and a more recent Papuan element. The address served also to open a joint discussion between Sections A, C, D, E, and M on "Biological, Geological, and Physical Evidences regarding the Relationship of Australia to other Lands, with special reference to the Continental Drift Theory."

In Section E (Geography and History), Prof. Ernest Scott took as the title of his presidential address "The Discoveries of the Western Australian Coast, with especial reference to Dampier and D'Entrecasteaux," in which he gave the results of an examination of documents bearing on the history of the ill-fated D'Entrecasteaux Expedition in the Archives Nationales in Paris.

The presidential address in Section F (Ethnology and Anthropology), by Prof. F. Wood Jones, contained caustic comment on the treatment meted out to the Australian aborigines in the past, and urged that the only way in which the race can be saved from extinction is by establishing native reserves, where the natives can live their own lives under natural conditions and be protected from pauperisation.

In Section G (Social and Statistical Science) the president, Major L. F. Giblin, took as the title of his address "Federation and Finance—an Examination of the Financial Relations of States to a Federal Commonwealth." In this he showed that the present financial arrangements between the Commonwealth and the States, including taxation, are almost exclusively on a *per capita* basis, which is inequitable, as wealth and population do not run parallel.

Sir Charles Rosenthal, president of Section H (Engineering and Architecture), was unable to attend, but forwarded his address on "Nation Building," which was read to the Section. The address dealt with the dependence of the progress of civilisation on engineering and architecture, and amongst other things urged the necessity on strategic and economic grounds for a uniform gauge for the Australian railways.

In Section I (Sanitary Science and Hygiene) the president, Dr. F. S. Hone, gave an address on "Notification and its Relation to the Prevention of Disease," in which he showed the great need for co-ordination and reform of the methods of notification in use in the Australian States. To make notification effective for controlling disease, the number of permanent medical officers of health will have to be increased.

In Section J (Mental Science and Education) Mr. P. Board spoke on "Economic and Social Values in Education." Education creates the soul of the nation, acting as the sum of the effects of all the teachers on all the pupils. An extension of the school age is desirable, but will probably require some form of family endowment.

Mr. C E. Lane Poole, president of Section K (Agriculture and Forestry), who was unable to attend, forwarded an address on "Forestry and Land Settlement." Forestry is agriculture on a long rotation, and to convert good forests into poor grazing land, as so often happens in Australia, is economically unsound; also the wholesale destruction of forests affects the climate adversely.

Prof. J. Douglas Stewart addressed Section L Veterinary Science) on "The Relationship of Veterinary Science to the Prosperity of the State." Heavy losses of stock are caused annually by parasitic and other diseases These can be combated successfully only by preventing infestation, but this requires a knowledge of the life history of the parasites, which in many cases we do not possess Much research is needed, but the veterinary services of the Commonwealth are sadly undermanned.

In Section M (Botany) Prof A J. Ewart gave his address on "Past, Present, and Future Development of Botanical Science," dealing with the killing of weeds by poison, which at present is done on purely haphazard and empirical lines, the need for botanical research in Western Australia, and modern views on the ascent of sap in trees.

In the new Section N (Physiology and Experimental Biology) Prof W. A. Osborne gave the presidential address on "The Study of the Reflex." The response to changes in environment is one of the most obvious manifestations of life, and the higher the organism the wider the range of environmental changes to which it is sensitive. In man the highest form of reflex action is found in the emotions. Prof. Osborne suggested that many body changes that seem without purpose in the individual become clear when the individual is regarded as a member of a society, as they express the interaction between him and his fellows.

Most of the sections had very full programmes. Intersectional discussions were a prominent feature of the meeting, the following discussions being held in addition to those already mentioned: "Catalysis and Enzyme Action" and "Hydrogen-ion Concentration" (Sections B and N), "Teaching of Hygiene in Schools" (I and J), "Soil Classification and Survey" (B, C, K, and M), "Adult Education and the Workers' Educational Association" (E, G, and J), "Poison Plants" (B, K, L, and M), "Water Supplies—Domestic, Agricultural, and Pastoral" (B, C, H, I, K, L, and N), "Treatment of Low-grade Ores" (B and H), "Biological Control of Pests" (D, K, L, and M), and "Timber Preservation" (B, H, K, and M).

Danish Observations of the Planet Jupiter.[1]

THE observations of the planet Jupiter made at the Urania Observatory, Copenhagen, during the period 1919–24 are summarised in the publication before us. By far the greater part of the report, however, deals with the observations secured during the very remarkable apparition of 1919–20—an apparition which saw the revival of the well-known hollow in which the Red Spot normally lies, the south tropical disturbance, and the south component of the south equatorial belt—all of which had disappeared in the earlier part of 1919. In the succeeding apparitions, bad meteorological conditions, and later the low position of the planet in the sky, rendered systematic work impossible. We accordingly limit our reference to the discussion of the 1919–20 observations.

---

[1] La surface de la planète Jupiter 1919–1924 Par C. Luplau Janssen. (D. Kgl Danske Vidensk. Selsk Skrifter, naturvidensk. og mathem. Afd, 8 Række, XI, 1) Pp. 88+[illegible] plates. (København: Andr. Fred. Høst and Son, 1926.) 10 kr.

The work done may be divided into three parts:

(1) Micrometrical measures for determining the co-ordinates of individual spots.

(2) Micrometrical measures for determining the latitudes of the belts.

(3) Descriptive notes and drawings of the surface features.

M. Luplau Janssen is a firm believer in determining the longitudes as well as the latitudes of Jovian markings with the micrometer, but some eye-estimated transits across the central meridian were also recorded. Many of the older observers of the planet will recollect the discussions which took place several years ago as to the relative merits of the two methods of deriving longitudes. A comparison of M. Luplau Janssen's micrometric results with central meridian transits by other observers shows the accuracy attained to be of much the same order, but it seems to the reviewer that in a given time a considerably larger number of spots can be observed by the transit method, which is a matter of great importance. On the other hand, valuable results can, of course, often be obtained with the micrometer of an object which has already been observed by the transit method, or for some other reason cannot be observed at its central passage. Micrometer measures also have the advantage of furnishing values for the equatorial as well as the polar diameter of the planet, and from his series of observations in 1919–20, M. Luplau Janssen deduces the figures 37″·72 and 35″·54 respectively at mean distance, which gives for the oblateness of the disc the value $\frac{1}{17}$. The figures for the equatorial and polar diameters at present adopted in the physical ephemerides are 37″·87 and 35″·35.

In the discussion of the observations of individual spots, the conclusions drawn suffer from the, relatively speaking, small number of longitude determinations. In fact, the identifications in some cases seem to the reviewer to be entirely erroneous. A striking example is found in the case of some remarkable spots observed in the south tropical zone (the zone between M. Luplau Janssen's bands IV. and V.). On p. 66 of his report five observations are taken together as referring to one and the same object, but if we accept the conclusions arrived at in the twenty-second report of the Jupiter Section of the British Astronomical Association recently published, which are based on a very much larger number of observations, we find that they actually belong to four separate objects, and that what is, perhaps, the most interesting fact revealed during the apparition—namely, the abnormal drift in opposite directions of two pairs of spots—has been entirely missed. Similarly, when all the available material is considered it appears that mistakes in the adopted identifications are accountable for some of the large irregularities of motion attributed to certain other spots by M. Luplau Janssen.

A valuable part of the report is that which contains a summary of the micrometrical measures of the latitudes of the belts and a comparison with results obtained by other observers in previous years. As has been often remarked, the latitudes of the belts show considerable variations, and especially has this been the case in recent years with the north edge of the north equatorial belt (M. Luplau Janssen's band III.). M. Luplau Janssen considers that there is evidence in the measures of some of the belts of changes of a periodic nature which are related to the position of the planet in its orbit. It may be questioned whether the available evidence is sufficiently strong to warrant such a conclusion, but the matter is certainly worth careful investigation, and there can be no doubt that measures of the positions of the belts (as emphasised several years ago by the late Prof. G. W. Hough) should be regarded as an important part of the work on Jupiter. M. Luplau Janssen lays emphasis on the stability in position of the south equatorial belt (his band IV.); yet it is worth noting that it is this belt which in 1919 and again in the present year has faded to such an extent as to become invisible save for its north component. Overlying vapours may perhaps be accountable for the effect observed, but on the other hand, in 1920 the revival was attended by disturbances which seemed to indicate some deep-seated cause in the planet's interior.

At the end of the report are seven plates containing 41 drawings, 37 of which belong to the apparition of 1919–20. These drawings illustrate the remarkably rapid and amazingly complicated changes which were associated with the great revival of the south equatorial belt and the south tropical disturbance during that apparition.

Taken as a whole, the report contains a mass of valuable data which will be very welcome to all students of the planet.

The Problem of Secretion.

THE attention of those who are interested in the problem of secretion is directed to a series of three papers by Dr. Robert H. Bowen, of Columbia University, New York, which have appeared in the current volume of the *Quarterly Journal of Microscopical Science* (vol. 70, parts 1, 2, and 3), and especially to the very capable critique of the topography, structure, and function of the Golgi apparatus in glandular tissue which he has given in a fourth paper (part 3, October 1926). Believing that the older theories of secretion had broken down and that the field was clear for the thorough examination of the Golgi apparatus as a synthetic intermediary in the process of secretion, he has concentrated his attention on this subject and has made only brief references to the secretory possibilities of other components of the cell.

Dr. Bowen concludes that the Golgi apparatus is present from the beginning in all kinds of secretory cells, and, when large numbers of secretory granules are being produced, becomes greatly hypertrophied, establishing a volume in rough relation to that of the secretory products, the other elements of the cell diminishing more and more. The topography and behaviour of the Golgi apparatus are different in different kinds of glands, but can be divided roughly into three general types characteristic of cells which produce serous, mucous, and lipoidal secretions. The secretory granules make their first appearance only within the area delimited by the Golgi apparatus. In a few cases there are indications that the secretory granules arise in close connexion with the Golgi material, and in fact that there is a constant and intimate topographical association between them. Dr. Bowen concludes that the secretory granules are differentiated by the Golgi material, but that no direct transformation of one into the other occurs, such as has been claimed by some authors who have advocated the mitochondrial origin of secretions. Dr. Bowen suggests that the Golgi material is structurally homologous throughout the range of animal cells, and that the so-called idiosomic substance sometimes associated with it is to be looked upon as one phase of a duplex system in which the relative development of lipoidal and idiosomic substances may undergo considerable variation.

Having established a probability in favour of the essential homology between secretory granules and the acrosome of the animal sperm, Dr. Bowen suggests that the relationship between the Golgi apparatus and the secretory granules is homologous to that existing between the Golgi apparatus and the acrosome, and that our more complete understanding of the latter phenomenon can be used as a basis for interpreting the much more obscure phenomena in the gland cell. He adds that the establishment of the views developed in his paper must depend finally upon further critical evidence from favourable material bearing upon the exact relation which exists between the individual secretory granule and the Golgi complex.

Dr. Bowen holds that no cytological evidence of the origin of secretory products from the nucleus receives any acceptance at the present time. The nucleus can be considered as the source of secretions only in the indirect sense that it may possibly exercise some control over the process as a whole, or may collaborate with other parts of the cell-system in preparing materials for the synthetic operations of the Golgi apparatus.

When a cell is divided into a nucleated and a non-nucleated portion, the latter is able to carry on synthetic activities for a brief period only; meanwhile the nucleated part regenerates and appears none the worse for the operation. Hence it was concluded that the nucleus is the centre of synthetic operations, and particularly of the formation of those intracellular enzymes upon which living activity is now supposed to depend. But it is at least equally possible that the nucleated piece alone continues capable of constructive metabolism because it possesses the complete cell-system, while in the non-nucleated piece the system is disrupted. Dr. Bowen remarks that if the Golgi apparatus could be eliminated, the cell would doubtless be fatally affected. While secretion is an activity in which the cell-system as a whole is probably involved, and over which the nucleus exercises some controlling influence, the actual synthetic centre for the differentiation of secretory granules is the Golgi apparatus. That this source of the visible secretory granules "is likewise the source of the invisible, intra-cellular enzymes . . . cannot at present be doubted, but our scanty knowledge of these things makes any hypothesis whatever almost pure speculation."

Forestry in Illinois and Great Britain.

It is common knowledge that the drain upon the world's resources of coniferous timber is very heavy, and that in some countries the outlook is regarded with increasing disquietude. In the "Third Report on a Forest Survey of Illinois," by C. J. Telford, the position of the State is explained with great clarity, and the parallel to the state of affairs existing in Great Britain is depicted. The present forests of the United States contain an estimated total of 481,800 million cubic feet of standing timber, the annual cut is 25,000 million cubic feet and the annual growth 6039 million cubic feet. "The virgin forests," the report says, "will carry us another 25 years, after which we shall probably be wholly dependent upon growth from cut-over lands. By utilising the entire 470 million acres of forest lands at prevailing rates of growth these cut-over lands can supply us with an estimated annual yield of 14,000 million cubic feet—a little more than half our present requirements. The conviction that satisfactory substitutes for wood will be found is untenable when the enormous amount of wood required is appreciated. This drain of 25,000 million cubic feet of standing timber a year means that for every hundred pounds of coal, iron, cement, petroleum and copper consumed the forests supply 67 pounds of wood, and the crop lands supply 44 pounds of all forms of crops, including cereals, seeds, clover, hay, forage, cotton, potatoes, sugar, fruit, and nuts. It is obvious that a satisfactory substitution for a commodity representing by weight two-thirds of virtually all the minerals consumed, or one and a half times all crops raised in the United States, is impossible. A timber famine will be more disastrous to Illinois than to any other State. Its manufacturing establishments employ 11·6 per cent. more hands than agriculture, transportation, and mining combined, and thirty per cent. of all persons employed in manufacture are in industries dependent upon wood. In the single item of lumber, Illinois consumes one-thirtieth the total lumber-cut of the world."

The process of forest destruction is far advanced in Illinois. Virgin timber has practically disappeared, and the present drain on the cut-over forests and second growth stands, unchecked, will, it is held, result in an early disappearance of all forests in the State. There was an increase in unforested waste land of 250,000 acres in the ten years from 1910 to 1920, and Illinois now has a total of 1,577,663 acres in this class. The 3,021,650 acres now forested are on lands unsuited to ordinary farming, and if cleared will generally revert to waste land. The state of affairs thus briefly delineated is sufficiently alarming from the industrial outlook alone and renders the more interesting the following comparison with the position of Great Britain.

"There is a striking parallel between Illinois and Great Britain in the total wood consumption and in the total area forested. Each annually consumes approximately the same quantity of wood—560,720,000 cubic feet for Illinois and 600,000,000 cubic feet for Great Britain; each has about the same area forested—3,021,650 for Illinois and about 3,000,000 acres for Great Britain. But Great Britain, despite a population of 437·5 to the square mile as compared with 115·7 in Illinois, and the consequent pressure for land, has deliberately undertaken to replant 1,770,000 acres, and this planting is being done at the rate of 20,000 acres a year. Illinois has never planted 200 acres of publicly owned forests, her farm woodlands are decreasing at the rate of 4500 acres a year, and the unimproved and waste land on farms is increasing at the rate of 25,000 acres a year."

Bird Flight.

In the *Transactions of the Royal Society of South Australia*, vol. i., 1926, an interesting contribution is made by Prof. F. Wood Jones on the flight of sea-birds. It has long been observed that many sea-birds spend protracted periods, sometimes soaring, sometimes gliding, and at any rate to the novice, apparently without a visible tremor of the wing. Their flight appears to be merely an ability to slide ahead with no other power than their own weight and a presumably instantaneous ability to readjust their planes and alter their cant and poise apparently largely by movements of the head.

As a result of close study and observation extending over many years, Hankin maintains that in the wake of a ship the air must possess a physical property which he terms 'soarability' by means of which sea-birds are enabled to extract from the air in that region an upward momentum. Presumably this must mean that the air in passing over the ship is set into a state of disturbed eddying of such a general direction of rotation and of such a distribution of intensity vertically that the bird experiences a lift it would not otherwise acquire.

Prof. Wood Jones, on the other hand, regards the soaring and gliding of pelagic birds as due rather to a morphological adaptation of the bird as an adjusted plane than to any chance condition of "soarable" air. Regarded in this way, he maintains, the zoned north and south distribution of the different morphological types of sea-birds and the failure of the albatross, for example, to follow ships into the tropics, well adapted as it is for gliding, must be investigated from the point of view of bird structure correlated to the environment to which it appears to be adapted. In the case of the albatross, there appears to be a perfect mastery of aerial conditions well to the south of the equator, a lessening mastery farther north, and a positive disability, laboured flapping flight, as the journey is made towards the equator. The same facts apparently hold with regard to the northern representatives.

Prof. Wood Jones points out, moreover, that the zonal distribution of species from the equator northwards is very similar to the distribution southwards from the equator, with a similar increasing ratio of weight to wing area, culminating at both poles with the southern penguins at one end and their extraordinary parallels, the northern auks, at the other. The clue to this gradation is to be sought in the increase in atmospheric density from the equator in both directions, so that a bird adapted for flight in the denser atmosphere finds difficulty in maintaining its gliding and soaring in the rarer atmospheres of the tropics. By indicating this new line of approach, Prof. Wood Jones undoubtedly has given a new impetus to the study of bird flight.

University and Educational Intelligence.

Birmingham.—Mr. H. Munro Fox, fellow of Gonville and Caius College, Cambridge, has been appointed to the Mason chair of zoology to succeed the late Prof. F. W. Gamble. Mr. C. G. C. Chesters has been appointed assistant lecturer in botany.

The Council has recommended to the Court of Governors that the title of emeritus professor be conferred on Thomas Turner, formerly professor of metallurgy.

Edinburgh.—At the graduation ceremony on December 17, the degree of D.Sc. was conferred on Baini Prashad, Superintendent of the Zoological Survey of India, the Indian Museum, Calcutta, for his thesis on (1) "Recent and Fossil Viviparidæ: a Study in Distribution, Evolution, and Palæogeography," and (2) "The Shell and Mantle of the Viviparidæ"; the degree of Ph.D. on R. K. S. Mitchell for his thesis on "Some β Octyl Esters of Substituted Acetic Acid"; and the degree of M.D. on Eric H. Ponder, with gold medal, for his thesis on "Studies in Hæmatology."

Applications are invited by Yale University for two Theresa Seessel Research Fellowships for the promotion of original research in biological studies. The value of each is 1500 dollars. Preference will be given to candidates who have already obtained their doctorate, and have demonstrated by their work fitness to carry on successfully original research of a high order. The holder must reside in New Haven during the college year, October to June. Applications, accompanied by reprints of scientific publications, letters of recommendation, and a statement of the particular problem which the candidate expects to investigate, should be made to the Dean of the Graduate School, New Haven, Conn., before March 1, 1927.

In the course of the past year inquiries were made by the Institution of Mechanical Engineers of the colleges and schools conducting approved part-time courses as to the ages and occupations of candidates for the Ordinary and Higher National Certificates in mechanical engineering. Information has been supplied from 85 colleges and schools in Great Britain in respect of 1000 candidates for the ordinary certificate and 334 for the higher certificate. The average age of the former candidates was about 19·5 years, and of the latter about 21·5 years. No less than 801 of the 1000 candidates for the ordinary certificate were between the ages of 18 and 21 years. Classifying the candidates in respect of occupation, it was found that apprentices of all classes constitute 71·3 per cent. of the candidates for the ordinary certificate, and 32·4 per cent. of those for the higher certificate, and that the combined proportions of trade apprentices and mechanics following these courses are 42·4 per cent. for the ordinary certificate and 37·7 per cent. for the higher certificate. The proportions of successful candidates were 52·5 per cent. for the ordinary certificate and 67 per cent. for the higher certificate.

The East Anglian Institute of Agriculture, Chelmsford, announces in its Calendar for 1926–27 that alterations during 1925–26 have enabled it to offer facilities for instruction of a more advanced character than that obtainable at any similar institute in Great Britain. The research work at present in progress includes deterioration diseases of potatoes, seeds mixtures, autumn versus spring sowings, composition of butter-fat in goat's milk, winter spraying, colonisation of salt marshes, bunt in wheat, wheat bulb fly, and Hessian fly. Agricultural economics courses include one on the history of British agriculture. Special courses on the agriculture of New Zealand, of Australia, and of Canada and South Africa, are provided. A list of appointments held by past students does not indicate that any of them have as yet gone abroad. The North of Scotland College of Agriculture has a very different record in this respect, a very large proportion of the posts held by its former students being in other countries. The Calendar of this College for 1926–27 announces, among other courses, a "Planter's Certificate Course" specially provided to meet the requirements of students intending to enter on service upon tea, coffee, rubber, sugar, and other plantations in tropical and subtropical countries. It extends over two complete winter sessions and one intervening summer session. No preliminary qualifying examination is prescribed. Nine students obtained the degree of B.Sc. in agriculture during the past session. The courses in forestry formerly provided by the College have been transferred to the University of Aberdeen. The Edinburgh and East of Scotland College of Agriculture has in the past, like the North of Scotland College, sent many students abroad, but the list published in its new Calendar of appointments gained by students shows a falling off in this respect. This College, like the East Anglian Institute, offers a course on the history of British agriculture based on Lord Ernle's "English Farming, Past and Present."

Calendar of Discovery and Invention.

January 1, 1801.—After the enunciation of Bode's law and the discovery of Uranus, it was thought there must be an undiscovered planet the path of which lay between the orbits of Mars and Jupiter. A group of astronomers, therefore, agreed to make a systematic search, and on January 1, 1801, Giuseppe Piazzi, at Palermo, saw Ceres, the first of the minor planets or asteroids. By 1845 four others had been discovered, but since the application of photography to astronomy many hundreds have been identified. Ceres, however, is the largest, being 485 miles in diameter.

January 1, 1855.—Among the methods used for determining the density of the earth is that introduced by Airy, who, in 1826 and 1828, with Whewell and Sheepshanks, made pendulum experiments at Dolcoath Mine, Cornwall. Later, he repeated these experiments at Harton Colliery, South Shields, at a depth of 1260 feet, and gave an account of these in a lecture at South Shields on January 1, 1855. The result he obtained gave 6·56 as the mean density—a value, however, considerably too high.

January 2, 1818.—The foundation of the Institution of Civil Engineers was due to six engineers, of whom the best known were William Maudslay, Joshua Field, and Henry Robinson Palmer. The first formal meeting was held at the Kendal Coffee House, Fleet Street, on January 2, 1818. On January 23, 1820, it was proposed to ask Thomas Telford to become president. He was formally installed on March 21 of that year, and held the presidency until his death in 1834. The first home of the Institution was at 15 Buckingham Street, Adelphi, and the first volume of *Proceedings* was issued in 1836.

January 3, 1752.—While spectrum analysis was due to Newton, it was the young divinity student Thomas Melvill who first used a prism for the examination of various flames; introducing sal-ammoniac, potash, alum, etc., into burning spirits. He gave an account of his experiments to the Medical Society of Edinburgh on January 3, 1752, while another paper of his was read to the Royal Society in 1753 by Bradley. (See NATURE, November 5, 1914, vol. 94, p. 263.)

January 4, 1896.—On this day Röntgen gave an account of his discovery of X-rays to the Physical Society of Berlin. His discovery was made on November 8, 1895, and was described in a paper entitled "On a New Kind of Rays," which appeared in the *Sitzungsberichte der Würzburger physik.-medic. Gesellschaft.* A translation of this paper was given in NATURE of January 23, 1896, together with an article and an X-ray photograph contributed by Mr. A. A. Campbell Swinton.

January 7, 1610.—No accidental discovery has had more far-reaching results than the discovery of the principle of the telescope. From the report of what Lippershey had done, Galileo made telescopes magnifying three, eight, and thirty times, and on January 7, 1610, at one o'clock in the morning, observed for the first time three of the satellites of Jupiter, and thus ushered in the era which has seen so vast an extension of our knowledge of the sky.

January 7, 1785.—The first to make a balloon ascent solely for scientific purposes, Dr. John Jeffries, on January 7, 1785, with the famous aeronaut Blanchard, crossed the English Channel from Dover to Calais, where a marble column was erected to commemorate the feat. On an ascent from London in 1784, Jeffries carried with him meteorological instruments and obtained samples of air at various heights for Cavendish.

E. C. S.

Societies and Academies.

LONDON.

British Mycological Society, November 20.—**W. J. Dowson**: An unusual species of Botrytis attacking Narcissus. The fungus is the cause of 'fire,' marking the leaves with one or more yellow patches. The spores of the fungus are very large, and germinate with as many as thirteen germ tubes after up to one hour in water or in dilute glycerine.—**Miss A. Lorrain Smith**: A new family of lichens. The lichen *Cryptothecia subnidulans* was described by the late Dr. Stirton, and has led to much difficulty in assigning it to a systematic position. Stirton's herbarium has revealed three additional species of the genus and two closely allied ones for which a new genus is proposed; the two genera form a family characterised by the apparently double-walled ascus containing septate or muriform spores and embedded in a lax peridium of interwoven hyphæ. Affinity with the fungi Myriangiales and Gymnoascales is suggested; the nearest lichen allies appear to be Thelocarpaceæ and Mycoporaceæ.—**O. V. Darbishire**: Isidia and soralia of lichens. Isidia in *Peltigera praetextata* develop endogenously from special hyphæ which make their way to the surface, breaking through the cortex or making use of a crack. The mature isidia are very highly developed assimilators. There is a primary cortex on the upper surface with walls of wavy outline. The secondary cortex is similar to the cortex of the thallus. The gonidia are fairly closely packed towards the upper cortex with a very loose arrangement just inside the lower cortex. This cortex is of one layer of cells, with sinuate walls and interrupted here and there by pores. Soredia also have an endogenous origin. A few gonidia are gradually surrounded by the fungus and the differentiating soredium is raised to the surface of the sorial tissue, from which it becomes detached as a reproductive organ.—**W. R. I. Cook**: The genus Ligniera. Cross inoculations have shown that several species which have been described are merely host varieties. Infection takes place by zoospores entering root hairs. Spores serve as a resting stage and for propagation within the plant. Reduction division occurs at the formation both of spores and zoospores. Conjugation has not been seen.—**W. A. Roach**: On the nature of disease resistance in plants, with special reference to the wart disease of potatoes. Wart disease is an example of physiological resistance. Evidence at present suggests that immune and susceptible varieties form two distinct classes and not end members of a continuous series. The reaction towards wart disease is unaffected by grafting on either a foliage system, a root system, or of a complete plant of opposite reaction to the disease. Immunity from, or susceptibility to, wart disease is therefore probably innate to the cell and must be sought in compounds which cannot cross a graft fusion layer unchanged, and so probably cannot leave a cell. These compounds may be proteins.

Geological Society, December 1.—**Howel Williams**: The geology of the Snowdon massif (North Wales). The area described is limited on the north-east by the Pass of Llanberis, on the south-east by the Vale of Gwynant, on the south-west by the Colwyn and Gwyrfai Valleys to near the village of Salem, and on the north-west by the supposed line of junction between the Cambrian and the Ordovician rocks. The general stratigraphical succession is made out. The exact relationship between the Ordovician and the Cambrian systems on the northern flank of Snowdon is uncertain. Ramsay's threefold division of the

Snowdon Volcanic Suite remains the most useful basis for its study. The Upper and Lower Rhyolitic series were derived from a potash-rich magma. The approximate age of the Snowdon Volcanic suite is inferred to be between Middle Llandeilian (zone of *Climacograptus peltifer*) and Middle Caradocian (zone of *Dicranograptus clingani*). Many dykes, inclined sheets, and bosses of quartz-porphyry, microgranophyre, and intrusive rhyolite occur on Snowdon, the largest intrusion being that of Crib Goch, formerly considered to be an outlier of the Upper Rhyolitic Series. Both mineralogically and chemically, the acid intrusive rocks resemble the Snowdon rhyolites. Pre-cleavage sills of augite-dolerite and spilitic dolerite occur at several horizons, and present various biotite- and copper-rich modifications. The major folding is of north-east-and-south-west strike, and occurred almost wholly after the period of basic intrusions. Its dominant expression is the so-called 'Snowdon syncline,' the north-western limb of which lies in a recumbent position in the area immediately south of Rhyd-ddu. The major folding was succeeded first by a cleavage of similar strike, and afterwards by a minor folding and thrusting due to pressures directed south-eastwards, the thrusting being most pronounced along the recumbent limb of the 'Snowdon syncline.' Finally, the area was broken into blocks by faults, most of which belong to the same family of movements as those just enumerated, although some may have moved again during the Tertiary era.—**Albert Heard**: On Lower Old Red Sandstone plants showing structure, from Brecon (South Wales). A new fossil plant locality is recorded from the Senni beds in the neighbourhood of Brecon. A new Lower Old Red Sandstone plant, *Gosslingia breconensis*, is recorded; the plant is rootless and leafless, with stomata and hairs; gregarious, erect, dichotomously-branched, cylindrical stems arise from dichotomously-branched rhizomes with rhizoids; the stems are circinately coiled in the apical regions. The stele consists of a large strand of tracheids which have both spiral and reticulate thickening, surrounded by protoxylem and phloem; the outer cortex of the aerial stem consists of four layers of thick-walled cells. Reniform appendages borne on special branches are interpreted as sporangia. There is also a peculiar organism resembling Pachytheca.

Society of Public Analysts, December 1.—**William G. Savage**: Recent advances in the bacteriological examination of food and water. The four tests used to differentiate the high and low types of coliform organisms in water and their value as indicators of excremental contamination are discussed. As regards milk, the value of examining centrifugalised deposits for the tubercle bacillus is considered, and new tests for distinguishing pathogenic streptococci from those of bovine origin not injurious to man are described.—**L. H. Lampitt, E. B. Hughes**, and **L. H. Trace**: On the presence and detection of furfural in vinegar. In the distillation of malt vinegar or wine vinegar, furfural is produced by the acid hydrolysis of the pentosans contained in the vinegar. Added caramel in vinegar will only give the furfural it originally contained as such. A modified aniline acetate test has been devised wherein the rose-coloured furfuraniline is extracted by an immiscible solvent, amyl alcohol. Thus dark-coloured vinegar may be tested for furfural without distillation. The test is quantitative.—**E. R. Dovey**: The rapid determination of opium in stomach contents. A standard solution is made from ordinary prepared opium which has itself been standardised to contain 10 per cent. of morphine and 5 per cent. of meconic acid. A measured quantity of the stomach washings are treated successively with dilute hydrochloric acid, mercuric chloride solution, and ferric chloride solution, and the resulting colour is matched with that given by the standard under the same conditions. The mercuric chloride inhibits the formation of any coloration with thiocyanic acid in the opium.—**C. H. Manley**: A rapid method for the sorting of butters and margarines. The method depends upon the butyric acid content of butter fat. The filtered fat is saponified, the soap solution acidified with sulphuric acid, and the insoluble fatty acids filtered off under specified conditions. The excess of sulphuric acid in the filtrate is neutralised (methyl orange as indicator) and the titration with standard alkali continued to neutrality, with phenol phthalein as indicator. The difference between the result and that obtained in a blank test affords a measure of the soluble fatty acids. The neutral solution may be used for determining the Kirschner value.

CAMBRIDGE.

Philosophical Society, November 22.—**H. W. B. Skinner**: On the polarisation of mercury lines emitted from a discharge tube in a magnetic field.—**C. F. Sharman**: The application of the method of the magnetic spectrum to the study of secondary electronic emission. The relative merits of the method of retarding potentials and of the magnetic spectrum for the investigation of the energy distribution of electronic emissions are discussed. The latter method was used in the case of the secondary emission excited in metal surfaces by a beam of electrons with energies between 100 v. and 1000 v. With a copper target, the distribution curve is very nearly independent of the energy of the primary beam. The results are in general agreement with those obtained by means of retarding potentials; there is, however, a discrepancy in the position of the low energy peak as given by the two methods.—**L. H. Thomas**: The calculation of atomic fields. The effective field V inside an atom is assumed to be that due to the nuclear charge and to electrons distributed uniformly in the phase space of their motion in the field at 2 for each h^3 of phase space corresponding to closed orbits. Thus

$$\nabla^2 V = \frac{64\sqrt{2}}{3}\pi^2 \frac{e^{\frac{5}{2}}m^{\frac{3}{2}}}{h^3}V^{\frac{3}{2}}.$$

The fields so calculated agree well with those that have been constructed to fit X-ray data.—**L. Wertenstein**: A contribution to the theory of diffusion pumps. The mercury vapour stream in a diffusion pump carrying gas from the 'low pressure' side to the 'high pressure' side creates a pressure gradient which explains the working of the pump. The pressure gradient is given by a diffusion formula (Gaede, Hertz) or directly by a dynamical method (corresponding to the calculation of diffusion coefficients by dynamical considerations: Langevin, Chapman). The agreement is excellent for hydrogen, a little worse for air. Hence the final ratio of pressures on 'high' and 'low' pressures side of a diffusion pump must be higher when the diffusion coefficient is smaller, *i.e.*, that so far as final vacuum is concerned, the diffusion pump is more efficient for heavier than for lighter gases. This result seems at first in contradiction with the fact that the diffusion pump pumps out quicker the lighter gases, but it was found that, at the same temperature, carbon dioxide was removed more perfectly than argon, and argon than hydrogen.—**W. Burnside**: On a group of order 25920 and the projective transformations of a cubic surface.—**P. A. M. Dirac**: The Compton effect in wave mechanics.—**J. B. S. Haldane**: A mathematical theory of natural and artificial selection. Part iv.—G. C. **Steward**: On the addition of the primary aberrations. In applying the characteristic function to particular optical systems three steps are necessary: the properties of the composite system must be examined in general, and then their dependence upon the corresponding properties of the component systems, and finally an examination must be made of the simplest components. The first and third of these have been undertaken elsewhere; a simple method is now given of achieving the second step—the method being applicable especially to the primary aberrations. Relations are obtained between the aberration coefficients of the composite system and the corresponding coefficients of the components.

LEEDS.

Philosophical and Literary Society, November 2.—P. K. **Dutt**: Anilopyrine and antipyrine (Preliminary Note). Anilopyrine alkohydroxides, in the absence of water, decompose spontaneously into 2-alkyl 5-pyrazolones, and a secondary amine. Further, the character of the substituents in position 2 and in the 5-amino group profoundly influences the yields of the two products. The fallacy of Michaelis's arguments in support of his bridge formula for anilopyrine is pointed out; there is no ground for discarding the anil structure of anilopyrine suggested by Stolz.—H. M. **Dawson** and C. R. **Hoskins**: Isohydric solutions and the velocity of chemical change. Measurements of the rate of reaction of acetone with iodine under the catalysing influence of isohydric solutions containing equivalent quantities of acetic acid and sodium acetate are in accord with the view that the reaction velocity corresponds with the sum of effects due respectively to the hydrogen ion, the hydroxyl ion, the acetate ion, and the undissociated acid. The proportion of the total effect attributable to the hydrogen and hydroxyl ions amounts to about 30 per cent. in a 0·005 molar solution, whereas this proportion is only about 0·2 per cent. in the case of a molar solution.—H. M. **Dawson** and L. H. **Angus**: The nature of solutions of the strong acids from the standpoint of the salt effect: the system nitric acid, sodium nitrate. The changes produced in the solubility of iodine in water by the addition of sodium nitrate can be expressed by an exponential formula $S = S_0e^{-kc}$. When nitric acid solutions (1·3 N and 2·7 N) are substituted for water, there is no change in the nature of the salt effect. The observations support the view that nitric acid is an almost completely ionised electrolyte.—R. **Whytlaw Gray** and H. **Whitaker**: A new method of determining the vapour pressures of aqueous solutions. This consists in suspending a droplet of solution from a fine silica spiral microbalance and measuring its weight when it has come into equilibrium with a solution of known vapour pressure placed in the balance case. Preliminary measurements with droplets of solutions of sulphuric acid surrounded either with sucrose solutions or with partially dehydrated oxalic acid have shown that the method is capable of giving accurate results.—B. A. **Burrell**: Atmospheric pollution in Leeds, 1922–25.—E. **Percival** and H. **Whitehead**: Biology of the mayfly *Ephemera Danica*, Müll. Observations have been made on the conditions under which *E. danica* exists. The nymphs are largely confined to sandy deposits where the particles consist chiefly of the coarse and fine sand fractions. The insects are positively rheotactic, negatively phototactic, and, in the light, burrow rapidly. These responses, along with poor swimming powers, tend to limit the distribution of the animals to the sandy regions of streams. An attempt has been made to relate quantitatively the occurrence of these nymphs with their habitat.—J. H. **Priestley**: The relation of cork formation to the endodermis in the shoot of the dicotyledon. An account is given of the occurrence and distribution of the polyderm in the shoot of *Rubus Idæus*, and of the suberised layers in the stem of *Camellia japonica*. In the light of these facts the distribution of cork in Camellia, superficial below the bud scale scars and pericyclic elsewhere in the axis, and the extent of the formation of wound cork in both stems, becomes intelligible. No interpretation of the influence of suberised endodermal structures upon cork formation in the dicotyledon shoot will be possible except upon the basis of detailed studies of this type.

MELBOURNE.

Royal Society of Victoria, November 4.—O. W. **Tiegs**: Metamorphosis of insects. Different degrees of metamorphosis are exhibited by different groups of insects. In dragon-flies there is probably but little change; in coleoptera there occurs a partial tissue disruption, and a partial tissue rejuvenation; in muscid flies a very profound tissue disruption occurs; but the most profound metamorphosis yet described occurs in the chalcid wasp (Nasonia), where *every* specialised larval cell disintegrates at metamorphosis, and, after removal by phagocytes, or after simply dissolving in the blood, is replaced by imaginal cells. In Nasonia the death of the larval cells is not due to phagocytic action, but is a direct consequence of their enormous growth in size, increase in the size of the larva being the result, not of an increase in the number of larval cells, but of an increase in their volume.—A. J. **Ewart** and Lesley R. **Kerr**: Contributions to the flora of Australia (No. 32). The paper contains a number of additions to the flora of the Northern Territory. *Euphorbia petala* n. sp. is related to *E. alsiniflora* and *E. Drummondii*; *Indigofera uncinata* n. sp. is a xerophytic adaptation of *I. australis*. *Eucalyptus Gillenii* n. sp. from the summit of Mount Gillen is related to *E. Oldfieldii*; *Velleia prostrata* n. sp., while related to *V. perfoliata*, has the bracts practically free at the base instead of connate. The collection of abundant material of Ptychosema in all stages of development has made it clear that this genus, and also Lamprolobim, belong not to the Galegeæ but to the Genisteæ.—J. M. **Baldwin**: The technique of the Nanson preferential majority system of election. This system of election, in contrast to other majority systems, fulfils the fundamental condition of majority representation, namely, that a candidate who could beat each of the other candidates separately must be elected. The technique evolved reduces the work of scrutineering to within practical limits. The technique developed has been tested in practice, the time for the tabulation being $Nn(n-1)/1000\ m$ hours (N voters, n candidates, m scrutineers). A method for reducing the number of candidates to ten is suggested which, while not rigidly accurate, is so unlikely to lead to error that the possibility may be neglected.

VIENNA.

Academy of Science, November 4 and 11.—J. **Zellner**, K. **Knie**, E. **Rosenbluh**, M. **Stein**, and J. **Richling**: Contributions to comparative vegetable chemistry (xv.). Chemistry of barks (fifth communication). Acer, Cratægus, Pavia, and Picea have yielded various substances, including ceryl alcohol, palmitic and stearic acids, invert sugar, tannins, etc.—J. **Zellner**, E. **Huppert**, R. **Klapholz**, K. **Knie**, O. **Pollatschek**, A. **Spitzer**, J. **Richling**, and M. **Stein** (xvi.): Chemistry of plants with milky sap. Diary of Societies.

SATURDAY, JANUARY 1.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. V. Hill: Nerves and Muscles: How we Feel and Move: (3) The Heart and some other Muscles.

MONDAY, JANUARY 3.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 3.30.—F. Rodd: Camels and Caravans (Christmas Lecture for Young People).

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4.30.—Capt. T. W. E. Higgens: Man and his God: The Origin of Religion in the Gentile World as taught by St. Paul.

INSTITUTION OF AUTOMOBILE ENGINEERS (Western Centre) (at Merchant Venturers' Technical College, Bristol), at 6.45.—Prof. W. Morgan: The Optical Indicator as a Means of Examining Combustion in Internal Combustion Engines.

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8.—J. H. Coste and Col. Butler: Modern Developments in the Treatment of Sewage.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—B. Anrep: Mosaics.

TUESDAY, JANUARY 4.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. V. Hill: Nerves and Muscles: How we Feel and Move: (4) The Lungs and Blood: How the Muscles get Air and Fuel.

INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts), at 7.—Dr. B. A. Keen: The Place of the Tractor in Soil Cultivation.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN, at 7.—M. Adams: Impressions of America and Canada—Photographic and otherwise.

HULL CHEMICAL AND ENGINEERING SOCIETY (at Hull), at 7.45.—G. H. M. Hutchinson: Refrigeration.

INSTITUTION OF AUTOMOBILE ENGINEERS (Coventry Graduates' Meeting) (at Broadgate Cafe, Coventry), at 7.45.—W. N. Haynes: Recent Developments in Motor Cycle Engine Design.

WEDNESDAY, JANUARY 5.

ROYAL SOCIETY OF ARTS, at 3.—Prof. C. R. Darling: The Story of a Wireless Valve (Dr. Mann Juvenile Lectures) (1).

PHILOSOPHICAL SOCIETY OF ENGLAND (at 123 Piccadilly), at 4.30.—Rev. J. B. Jaggar: The Philosophy of Faith.

GEOLOGICAL SOCIETY, at 5.30.—C. S. Elton: The Nature and Origin of Soil-Polygons in Spitsbergen.—Dr. F. Dixey: The Tertiary and Post-Tertiary Lacustrine Sediments of the Nyasan Rift-Valley.

ROYAL SOCIETY OF MEDICINE (Comparative Medicine and Tropical Diseases and Parasitology Sections), at 5.30.—Discussion on Trypanosomiasis in Man and Animals.

INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.—G. H. Nash and others: Informal discussion on The Acoustic Problems of Microphones and Loud-Speakers.

INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at Caxton Hall), at 7.—R. E. Herring: The Supervision during Erection and Maintenance of a Low Pressure Hot Water Heating Apparatus.

ROYAL MICROSCOPICAL SOCIETY (Biological Section).

NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS (Middlesbrough Branch, Graduate Section) (at Middlesbrough).—C. Boast: Marine Condensing Plant.

THURSDAY, JANUARY 6.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. V. Hill: Nerves and Muscles: How we Feel and Move: (5) Nerves and Muscles Working Together.

INSTITUTION OF ELECTRICAL ENGINEERS, at 6.—A. R. Cooper: Electrical Equipment of Track on the Underground Railways of London.

INSTITUTION OF THE RUBBER INDUSTRY (Birmingham and District Section) (at Grand Hotel, Birmingham), at 7.—A. W. T. Hyde: Physical Tests and their Significance.

SOCIETY OF CHEMICAL INDUSTRY (Bristol Section, jointly with Fuel Section) (at Bristol University), at 7.30.

SOCIETY OF DYERS AND COLOURISTS (West Riding Section) (at Bradford).—Prof. F. M. Rowe: Soledon Colours (SDC) and their Development on Cotton and Wool.

INSTITUTION OF MECHANICAL ENGINEERS (Manchester Branch) (at Manchester).—R. Potter: Pulverised Fuel.

FRIDAY, JANUARY 7.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 3.30.—J. H. Reynolds: A Little Journey in the Kingdom of Iceland (Christmas Lecture for Young People).

INSTITUTION OF ELECTRICAL ENGINEERS (South Midland Centre) (at Engineering and Scientific Club, Wolverhampton), at 7.—W. Wilson: Electrical Research.

INSTITUTION OF MECHANICAL ENGINEERS (Informal Meeting), at 7.—Dr. C. H. Lander: Developments in the Carbonisation of Coal.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (Pictorial Group), at 7.

PHOTOMICROGRAPHIC SOCIETY (at 4 Fetter Lane), at 7.—F. Martin Duncan: Notes on the Photography of Plant Tissues.

SOCIETY OF CHEMICAL INDUSTRY (Manchester Section) (at 16 St. Mary's Parsonage, Manchester), at 7.—Short Papers.

GEOLOGISTS' ASSOCIATION (at University College), at 7.30.

JUNIOR INSTITUTION OF ENGINEERS, at 7.30.—P. J. Haler: Distortion in Heat-treated Case-hardened Carbon Steels.

SATURDAY, JANUARY 8.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. A. V. Hill: Nerves and Muscles: How we Feel and Move: (6) Speed, Strength, and Endurance.

CONFERENCES.

ANNUAL CONFERENCE OF EDUCATIONAL ASSOCIATIONS (at University College).

Thursday, December 30, at 3.—Sir Henry A. Miers: The Choice of What is Good for Others (Presidential Address).

Friday, December 31, at 11.30 A.M.—Earl of Clarendon: Empire Settlement and Development.—King Alfred School Society, at 3.—J. Wicksteed: The Evolutionary Value of Co-Education.—Royal Drawing Society, at 5.30.—H. H. Peacock and P. Griffith: The Education and Development of Æsthetic Ability in Young People.

Saturday, January 1.—Educational Handwork Association, at 2.—J. H. Everett: The Teaching of Practical Elementary Science.—Leplay House, at 3.—Discussion: The Periodical Observation. Its Use for Observational and Regional Survey Work.—International Language (Ido), at 5.—G. H. Richardson: International Language. The Present Situation and the Prospect.

Monday, January 3.—Eugenics Society, at 11 A.M.—Prof. E. W. MacBride: The Nature and Origin of Racial Differences.—British Psychological Society (Education Section), at 6.—Discussion: S. J. F. Philpot, Miss Barbara Low, and others: The Cinema in Relation to the Mind of the Child.—British Association for Physical Training, at 5.30.—C. S. Thomson: Hygiene and Physical Training.

Tuesday, January 4.—School Nature Study Union, at 5.—Dr. E. J. Salisbury: Salt Marsh Vegetation.

Wednesday, January 5.—Society for Experiment and Research in Education, at 10.30 A.M.—J. H. Whitehouse and others: Creative Education.—Child Study Society, at 5.30.—Miss Lilian Barker: The Girl Delinquent.—British Esperanto Association, at 5.30.—Rev. Prof. T. G. Bailey: Esperanto in the World to-day.

Thursday, January 6.—National League for Health, Maternity, and Child Welfare, at 5.—Miss Gardiner, Dr. R. J. M. Horne, and others: Discussion: Open Air Schools.—London Head Teachers' Association, at 5.—W. A. Brockington and Prof. Godfrey Thomson: Technique of Examination.

Friday, January 7.—British Broadcasting Company, at 11 A.M.—J. C. Stobart and others.

GEOGRAPHICAL ASSOCIATION (at London School of Economics, Houghton Street, Aldwych, W.C.2).

Thursday, January 6, at 11.30 A.M.—Major C. Patrick: Mapping from Air Photographs.—At 5.—Miss Eileen Power: Trans-Asiatic Caravan Routes in Ancient and Modern Times.—At 8.—J. Fairgrieve: Geography Teaching in Primary Schools.—Sir Henry G. Lyons: Geography in the Universities.

Friday, January 7, at 10 A.M.—Prof. H. J. Fleure: The Teaching of Geography.—At 11.45.—Sir C. F. Close: Population Problems of the Empire (Presidential Address).—At 2.—Col. Jack: The Work of the Ordnance Survey Department.

Saturday, January 8, at 10 A.M.—Prof. T. P. Nunn: Boy Scout Geography.—At 11.30.—Mrs. Ormsby: Regional Survey in a Large City.

JANUARY 3 AND 4.

MATHEMATICAL ASSOCIATION (Annual Meeting) (at London Day Training College).

Monday, January 3, at 5.30.—Prof. R. W. Genese: An Elementary Exposition of the Methods of Grassmann.

Tuesday, January 4, at 10.30 A.M. to 12.30.—Prof. M. J. M. Hill: The Teaching of Mathematics (Presidential Address).—Prof. A. Lodge: The Importance of including in School Work the Graphic Solution of Quadratic Equations.—G. Goodwill and others: Discussion on The Choice of Units in the Teaching of Mechanics.—A. C. Heath: On the Approximation to Irrational Numbers by Rationals.—At 2.30 to 4.15.—Prof. H. F. Baker: Can the Range of Geometry taught in Schools be Widened?—W. C. Fletcher: Geometrical Congruence.—A. T. Edwards and others: Discussion on The Relation of Art to Mathematics.

EXHIBITION.

JANUARY 4, 5, AND 6.

SEVENTEENTH ANNUAL EXHIBITION OF THE PHYSICAL SOCIETY AND THE OPTICAL SOCIETY (at Imperial College of Science and Technology, South Kensington), from 3 to 6 and from 7 to 10.

January 4, at 8.—Prof. E. N. da C. Andrade: Reproduction, with Contemporary Apparatus, of a Physical Lecture of the Early Eighteenth Century.

January 5, at 8.—Dr. C. V. Drysdale: A Lecture on Progress in Electrical Instrument Design and Construction.

January 6, at 8.—J. L. Baird: A Lecture on Television.

Forest Destruction and its Effects.

THE question of the action of forests on rainfall has been debated by foresters, agriculturists, engineers, and others for a long period, the discussion probably dating back to the time at which scientific forest conservancy was first introduced. In the tropical and sub-tropical parts of the world this is not, however, the point of primary importance. The vital factor for the community at large is the determination of how far the destruction of forests in catchment areas and on the sides of hills and mountains in the drier parts of a country affects, in the first place, the level of the water in the big rivers, a matter of extreme importance when the rivers are utilised for irrigation or power works; secondly, the decrease in the local water supplies and in local precipitations upon which the cultivator is dependent; and, thirdly, erosion and avalanches, and the destruction they cause in the fertile valleys beneath. Sudden floods may also cause enormous damage to railways, towns, and so forth. In India, which was the first part of the British Empire to give consideration to this aspect of the forest question, the matter has been the subject of discussion and reports through the whole of the past century, a statement which will perhaps come as a surprise to many in Great Britain.

The problem of affording protection to forests for the above causes alone is by no means new. In France and Germany special laws for the protection and extension of the forests and the protection of agricultural lands by means of the forest have long been in operation; and similar laws exist in the Italian States. So far back as 1475 the subject attracted the attention of the famous Venetian Council of X., by whom a law was passed on January 7 of that year, regulating in great detail the clearance of the forests on *terra firma*. The mountain forests especially were protected by judicious regulations, which were renewed from time to time down to the very year of the extinction of the old republics. Tuscany and the Pontifical Governments were equally provident.

History has since shown that the wholesale destruction of forests in Spain, Italy, Sicily, Greece, and Macedonia has resulted in a great deterioration of climate over considerable tracts, due to loss of moisture, the sterilisation of the soil, and excessive erosion.

Although now well known, the chief action of the forest may be stated briefly as follows: The great factor in mountainous and hilly country is the maintenance of tree growth on parts of the area. In the case of bare slopes the rain rushes rapidly down, causing erosion, only a fraction percolating into the soil, and is carried rapidly away, giving rise to spates and perhaps to serious floods, since the old channels of these streams or rivers are no longer able to carry the excess water of flood levels. A hot sun bursting out on to the slope after the rain quickly dries up the thin layer of moisture covering it. In the hotter parts of the globe subject to heavy rainstorms or monsoons the rushing water starts gullies which eventually become ravines, all surface soil is rapidly washed away, and in the course of years the hillside is eaten into, rubble and boulders being sent down to cover up valuable lands below. When the area is under trees, a portion of the rain, falling on the crowns, drips slowly down on to the layer of humus beneath and sinks into it. The larger portion, perhaps, falls direct on to the forest floor, where it is gradually absorbed in the soft covering which takes it up as a sponge. The water then percolates slowly downwards, filling up springs and underground reservoirs, and reaches the streams in a retarded manner. The flow in the latter is consequently more even and regulated, as also the amount of water which eventually reaches the rivers. The latter can therefore be more depended upon to maintain a normal level when it is required to utilise them for irrigation or power works. The roots of trees protect the surface by holding up the soil, and thus directly prevent denudation.

It is possible to give some concrete examples of the effects of the destruction of teak forests in India during the first half of last century, owing to the large demands for this timber from rapidly expanding markets.

The slopes on the west coast of the Bombay Presidency were once, even in the early days of British occupation, covered with magnificent, valuable, and extensive teak forests. These have long since been cut out, some disappearing for good. The denudation of the Deccan Highlands and the Eastern Ghâts has resulted in excessive erosion and the gradual silting up of the rivers. When the Dutch, French, and English first built settlements on the Coromandel Coast, it was possible to take ships up the Godaveri and Kistna. The English port of Narasapur and the French one of Yunaon, both on the Godaveri, were once the chief ports on this coast. They can now be reached only at high tide by small native shallow-draught craft. Last year the present writer had arranged to go down the Godaveri from Sironcha, on the frontier of South Chanda (Central Provinces) and the Hyderabad State, to Rajamundri, as he wished to carry out investigations in connexion with the effects of forest denudation on this river. It was early in March, the commencement of the hot weather season only. Inquiries elicited the fact that few rafts were now going down, owing to the extensive sandbanks already drying off in the river, and that even by dugout canoe, delays from stranding on sandbanks would be inevitable. Some hundred years ago this great river was the chief artery or high road into the interior! At Masulipatam, Dutch ships used to ride at anchor close up to the port, whereas at the present day even small native vessels have to anchor five miles out in the roads owing to the silting up. Between 1840 and 1850, Dr. Gibson, the first Conservator of Forests in Bombay, drew up a list of the rivers and creeks on the Malabar coast, where on arrival in those parts ships used to ride at anchor, all the creeks having silted up within the memory of men then alive.

Dr. Cleghorn, who afterwards became the first Conservator of Forests in Madras, directed attention to the destruction of tropical forests at the meeting of the British Association in Edinburgh in 1850. A committee was appointed to consider this matter. Dr. Cleghorn submitted its report, which was confined to India, the only country for which information was available, at the meeting of the Association at Ipswich the following year. The report summarised the position, as then known to the few in India who had given attention to the matter, pointing to the great and uncontrolled destruction which was taking place, both at the hands of timber merchants and owing to the careless habits of the native populations, who grazed their cattle at will in the forests and fired them every year in order to encourage the growth of new grass. The indigenous tribes in the hilly country also practiced unchecked shifting cultivation, a practice second only to the lumberer in the destruction of fine forests. Under this method, which was a common habit in Europe in olden times, a patch of good forest is felled and the material burnt *in situ*; coarse grains are then sown on the clearing. The cultivator then sits down and awaits the harvest. Two or three crops are taken off the area; the weeds then become too strong (as he never troubles to weed) and he moves on to a fresh area. The enormous destruction of virgin forest this practice entails, when practised for centuries, has to be seen to be credited. Yet many of the tropical and sub-tropical forests in British Colonies and Dependencies are still subject to this the most pernicious and precarious form of so-called agriculture (as also to over-grazing and firing), the administrations responsible not having yet, apparently, understood the evils which attend it. The difficulties facing these Governments in prohibiting the practice or controlling it were all experienced in India, in one form or another, and overcome.

The encouragement given to the growth of tea and coffee and similar crops by British administrations in the Empire, whilst eminently praiseworthy if carried out on well-considered lines, has been productive of great harm in the past, and even the present day can scarcely be said to be free from anxiety on this score. In a report written in India in 1876 with reference to coffee planting, the following criticism is made:

> "The planters who come over from Ceylon are now giving a very high price for land, and the whole *mischief may be effected in a very short time*. It must not be supposed that coffee is at all a permanent cultivation; we have only to look at the Sampajee Ghât in Coorg, the Sispara Ghât in the Nilgiris, and parts of the Annamalais to see at once that it is very often very little better than the shifting cultivation of the natives. It pays a coffee planter *to take up a tract of primeval moist forest on our* mountain slopes for a few years; he gets bumper crops the third, fourth, and fifth years, but denudation of the soil and erosion goes on rapidly, and it does not pay him to keep it up many years."

Two other examples may be mentioned. In Ajmere-Merwara in Rajputana, all the waste and forest land was handed over to the people by Government in 1850. The hills were rapidly denuded of timber and grazing was uncontrolled. The crops are irrigated from tanks (ponds) formed by building embankments across ravines. Some of these were very old. The rainfall is scanty and comes in heavy showers. The water, rushing down in torrents, quickly eroded the denuded hillsides, the tanks filled up with silt and debris or the embankments burst. In 1869, at the end of a two-year famine, the region was described as follows: "The cattle had perished, the people had fled, large villages were entirely deserted and the country was almost depopulated." All this was due to the mistaken policy of giving to the people what they had clamoured for, the uncontrolled use of the forest lands. An even more classic example is that of the well-known Hosiarpur *Chos* in the Punjab. These hills were formerly fairly well wooded. A rapid increase in population followed the advent of British administration in 1846. The consumption of forest produce augmented, the herds of grazing cattle multiplied excessively, and complete denudation ensued. This was followed by erosion, broad stretches of sand invading the plains beneath, with the result that the arable lands of 940 once prosperous villages were covered with sand, which laid waste upwards of 70,000 acres of fertile lands. In 1900 this formerly rich district was traversed by numerous broad, parallel, sandy belts cut out of the crop-bearing and fertile area.

In India these matters are now well understood, and the Forest Department, supported by the Government, has control of the great forest areas. Proofs of the disadvantages and disasters following the uncontrolled wasteful utilisation of the forests in mountainous and hilly country are not therefore wanting. It is known that the same processes are at work, and the same mistakes are being made, in our Colonies. It is the habit of British *administrations to work in water-tight compartments*. Probably the major portion of the difficulties being experienced in different parts of the Empire have been solved, or are approaching solution, in one or other of the provinces in India. They present no new features, as some appear to think, as the above-quoted examples go to prove. The chief difficulty is that action is delayed until almost irretrievable damage has been done and then the forester is asked to reafforest the areas so denuded. This entails an enormous expenditure, great skill, with success ever hanging in the balance.

Attention was directed to this subject at the meeting of the British Association in Edinburgh in 1920, when a paper dealing with the Indian forests was read. Resolutions of the same kind were also passed by the World's Forestry Congress held at Rome in May 1926. As an outcome of last year's meeting of the British Association at Oxford, the chairman of the Forestry Sub-Section, Lord Clinton, drew up for the council a brief statement dealing with the destruction of forests on hill slopes, with special reference to the tropical forests of the Empire. This memorandum has been submitted to the Secretary of State for the Colonies, by whom it is being communicated to the Colonies and Protectorates. It may be hoped, therefore, that the chief factors of destruction, namely, shifting cultivation, excessive grazing and the firing of forest lands, may receive that measure of considered control which the expert forestry services under the Colonial Office are fully capable of inaugurating if supported by the several administrations.

Racial Likeness.

Biometrika. Vol. 18, Parts 1 and 2. (London: Galton Eugenics Laboratory, University College, 1926.)

THIS instalment of *Biometrika* presents a strong claim on the interest of students of physical anthropology centred in the account which Prof. Pearson gives of the "Coefficient of Racial Likeness." This is a single numerical expression designed to measure the degree of resemblance (or divergence) of two groups of mankind. While this coefficient is the chief feature of research described in these memoirs, there is a second which should not be overlooked. The latter is an expression measuring the degree of resemblance of two groups in respect of a single character. It differs consequently from the coefficient of racial likeness, which sums up evidence furnished by a number of contributory characters.

Miss Hooke is responsible for the first paper, entitled "A Third Study of the English Skull." The previous studies were made by Dr. Macdonell (*Biometrika*, vol. 3, p. 191, and vol. 5, p. 86) upon human skulls found in London, the first series coming from Whitechapel, and the second from Moorfields. Both were regarded justifiably as representative of Londoners of the seventeenth century. Miss Hooke disposes of a collection of skulls from Farringdon Street, and refers them to the seventeenth century likewise. Tables of measurements supplement the descriptions, while type-contours extend the basis of comparison with other groups. The coefficients of racial likeness have been determined, and when the results of comparing the Farringdon Street groups with those from Whitechapel and from Moorfields in succession are surveyed, the conclusion is reached that "the three are very similar, but not sufficiently so to warrant the assumption that they are drawn from a single homogeneous population" (p. 102). Resemblance is discovered between the Farringdon Street skulls and certain Scottish skulls, but marked divergence from the skulls at Rothwell, Northants, measured and described by Prof. Parsons.

Dr. Morant contributes the second paper, reporting his inquiry into the characters of British crania at different historical epochs. First he reviews representatives of the Long Barrow (neolithic) population, followed in succession by those of the Bronze Age, the Iron Age, and the Anglo-Saxon period of dominance. The survey of these groups includes references to the arithmetical means of the measured characters, to the coefficient of racial likeness, to the coefficient termed 'α' (which measures the degree of likeness in respect of any single character), to measures of variability, and to type-contours. Discussion of the conclusions is carried into the next memoir.

This paper contains the observations made by Miss Hooke and Dr. Morant conjointly on the conclusions to which their researches have led them. The ascertained values of the coefficient of racial likeness are brought together impressively in Table I. One coefficient is particularly remarkable, by reason of the emphasis it lays upon resemblance. The resemblance thus emphasised is that of the Whitechapel skulls to the British Iron Age skulls. This resemblance surpasses in closeness everything else in the table.

The fourth paper is by Prof. Pearson himself. He recalls the difficulty of comparing two groups of mankind when the numbers of one or both are relatively small. He points out the difficulty of summing-up on the results of comparing characters one by one. He describes steps leading to a formula capable of measuring the degree of resemblance (or divergence) of the two groups. This formula he terms the coefficient of racial likeness; and (in regard to its indications) the nearer the numerical value is to zero the more closely associated are the two groups, in the sense that they are more probably samples of the same population.

Prof. Pearson has at his disposal no less than 757 coefficients of racial likeness. Their numerical values range widely, 110 of them being less than unity, while 39 are higher than 31. Prof. Pearson suggests a classification with twelve subdivisions called grades. In Grade I. are all coefficients less than unity. They denote very intimate association. At the other end of the scale is Grade XII., including all coefficients in excess of 31, indicating very wide divergence. A boundary is fixed arbitrarily at the number 13, and this is to mark the extreme limit at which resemblance can be claimed.

The series of coefficients is next reviewed; and in regard to those with high numerical values indicative of wide divergence, Prof. Pearson is able to claim that in the vast majority of the instances available the coefficient brings confirmation to conclusions formed on independent grounds. In a corresponding manner, when scrutiny is directed to the coefficients denoting very intimate association, it is difficult to find any pair of groups "which embraces two craniologically distinct races" (p. 114). Such facts ought to establish confidence in the intermediate values and indications of the coefficient. Of these values it is remarked that some are in their purport entirely novel, while others correct views held previously as to the relation of certain groups of skulls. One of the four examples illustrating these conclusions proclaims that the English skull is nearer to that of the men of the British Iron Age than to that of the Anglo-Saxons. The conclusion reached by Miss Hooke and Dr. Morant in regard to the close association of the Whitechapel series and the British Iron Age skulls has been mentioned already. Here the setting is slightly different, and the relevant coefficients are adduced in support of the conclusion which it embodies.

Turning to the records, it appears that in association with the seventeenth century English (Whitechapel series) the British Iron Age skulls yield a coefficient of 0·38, whereas with the same English series the Anglo-Saxon skulls yield a coefficient of 2·98. At this point it is worth recalling that in 1904, when dealing with the Whitechapel and Moorfields series, Dr. Macdonell found confirmation of the suggestion made by Prof. Pearson that the Whitechapel skulls are closer to the Long Barrow British than to the Round Barrow British, Romano-British, Anglo-Saxon or "mediæval English" represented in the museums of this country. About sixteen years later, Prof. Parsons urged the claims of the Anglo-Saxon skull in this respect, against those of the Long Barrow skull. The evidence of the coefficient of racial likeness acquires a special interest in view of this difference of opinion, and the present series of memoirs provides the following data upon this subject.

COEFFICIENTS OF RACIAL LIKENESS.

Whitechapel and British Iron Age	0·38 ± 0·20
Whitechapel and Moorfields	2·05 ± 0·18
Whitechapel and Anglo-Saxon	2·98 ± 0·19
Whitechapel and Farringdon Street	4·15 ± 0·18
Whitechapel and Long Barrow (p. 100)	7·44 ± 0·18,
(or p. 55)	3·71 ± 0·18

The coefficient consequently places the British Iron Age skulls closest to the Whitechapel skulls. Thus it displaces both the Long Barrow skulls and the Anglo-Saxon skulls from the distinctive position claimed for them by their respective advocates. The data illustrate also the varying values of the coefficient resulting from the comparison of the Whitechapel series with each of the two other seventeenth-century series of Londoners.

Returning now to Prof. Pearson's paper, it will be found that he discusses the influence exerted upon the value of the coefficient by the number of the skulls available in the groups compared with each other, and again by the number and also the character of the observations employed. A plea for standardisation in these matters is also advanced by Prof. Pearson.

The application of the coefficient of racial likeness to the series of British crania has been taken above as an appropriate illustration. But although the associations there indicated and their grading may be novel, they are neither impossible, nor even extremely improbable. With such reflections in mind, attention is directed to the remarkable association assigned to Mori-ori and Fuegian skulls by the corresponding coefficient. Almost equally strange is the association indicated as existing between his Mori-ori (non-Mongolian) Tibetans.

The perusal of the list of records leaves a certain impression of caprice in the manifestations of the coefficient of racial likeness. For example, in one and the same population, namely, Londoners of the seventeenth century, the coefficient may range from 1·41 to 4·85 for male skulls and from 0·96 to 5·77 for female skulls, according to the characters employed and the pairs of groups compared. Again, the comparison of various pairs of Romano-British groups yields a range of the coefficient from 0·5 to 17·48. These records must needs be borne in mind and the explanations carefully weighed before the very striking values of the coefficients relating to Tibetans, Mori-ori, and Fuegians are made the basis of arguments affecting the movements of human racial types. At present, caution enjoins reliance upon the coefficient only where its numerical values are extreme (whether low or high) and its emphasis (whether laid upon resemblance or divergence) correspondingly pronounced.

In the fifth paper, Dr. R. W. Reid, emeritus professor of anatomy in the University of Aberdeen, describes two skeletons from St. Magnus Cathedral, Kirkwall, Orkney. The Icelandic Sagas and the Orkneyinga Saga provide Dr. Reid with evidence that the patron saint was executed (murdered is more correct), that the executioner used an axe, that after interment for twenty years the body was enshrined over an altar in Christ's Kirk, Birsay, and that after a sojourn there and in another church, the shrine was transferred to the cathedral. From the same sources Dr. Reid has ascertained that the body of the famous Norse St. Rognvald was buried likewise in the cathedral (of which he was actually the founder).

Each skeleton occupied a recess curiously excavated high up in a pillar of the choir of the cathedral. Dr. Reid comes to the conclusion that the remains from the south pillar are those of St. Magnus, and that those in the north pillar probably belonged to St. Rognvald. The osteological descriptions are accompanied by tables of measurements and by contour tracings.

Dr. Reid's conclusions make as close an approach to absolute identification as can be expected in the circumstances. Although not actually brachycephalic in terms of the proper index, both skulls by reason of their width tend in that direction. This point is mentioned in view of an opinion, based on experience elsewhere, to the effect that this tendency is very frequently to be remarked in the skulls of medieval ecclesiastics.

The photographs of the skull assigned to St. Magnus suggest the possibility that two kinds of mutilation, effected at different epochs, are present. It seems not impossible that a spade may have inflicted supplementary injuries now indistinguishable from those due to the executioner's axe twenty years earlier. The difficulty of the problem has long been recognised, and a discussion thereof will be found in the "Collected Scientific Papers and Addresses" of the late Prof. Rolleston (vol. 1, p. 286). W. L. H. D.

Archæology of Iron.

Iron in Antiquity. By Dr. J. Newton Friend. Pp. viii+221. (London: Charles Griffin and Co., Ltd., 1926.) 10*s.* 6*d.* net.

THE application of the analyses of metal objects to the study of archæology, especially in connexion with the problems of the bronze age, is becoming increasingly important owing to its bearing upon questions of cultural diffusion. If, for example, it were possible to determine by analysis the origin of the copper found in the various centres of early culture in which copper did not occur or had not been mined but had to be imported, we should probably be well on the way to solving some of the more obscure questions of pre-history. The work of the committee of the British Association which is seeking the source of Sumerian copper on these lines, when completed, may be expected to indicate how far such research is likely to be of practical utility in furnishing evidence in archæological and ethnological argument. This point is not without interest in the present connexion, as Dr. Friend, whose competence as an archæologist and metallurgist has been proved in a number of communications to the technical journals, in his "Iron in Antiquity" has not confined his attention to the study of that metal alone. He has felt it incumbent upon him to survey briefly the technological side of the stone, copper, and bronze ages, and has thus put readers who may not be archæologists in possession of the facts which are necessary to an understanding of the special problems with which primitive users of iron had to deal. Further, he refers incidentally to the arguments relating to the diffusion of culture which have been based by Prof. Elliot Smith upon the early use of copper in Egypt.

As regards the beginnings of iron, Dr. Friend is of the opinion that meteoric and not telluric iron was the form in which it was first used. The figures he quotes in reference to the amount of meteoric iron which probably was available for the use of early man appear adequate to meet the arguments of those who hold otherwise. It would have been an advantage had the primitive furnace, especially as it occurs in Africa, received a little more detailed treatment. It would then have been more clearly apparent that the process of smelting iron is one which presented no very great difficulty to primitive man. It would seem, however, that both early and primitive peoples were not fully capable of dealing with the product of the furnace. While the Vikings, for example, were able to produce satisfactorily an object of some size, such as an anchor, a thin strip of metal such as a sword, which would retain an edge and not bend, was frequently beyond their powers. The regular occurrence in sagas and legends of swords of fame each with its own special name is some measure of the difficulty the smith experienced in producing a satisfactory weapon. In its rarity it called for special commemoration. References to the ease with which the spears of African natives were bent are frequent.

Dr. Friend gives some interesting details relating to the quality and character of the metal in iron objects found in pre-Roman and Roman Britain. It is noteworthy that samples of Roman iron which have been tested for corrodibility compare favourably with modern mild steel of corresponding size.

Although Dr. Friend's collection of data from various sources is admittedly not exhaustive, as supplemented by his own observations and researches, it will be of very real assistance to students of archæology. The results of the qualitative and quantitative analyses are particularly useful and frequently illuminating. All sides of the subject are covered. The author touches upon the various uses to which iron was put—for ornament or for currency as well as for implements and weapons — whether it be in the prehistoric period, in early Egypt and Mesopotamia, India, China and Japan, or among primitive peoples. It may, however, be said in passing that the chapter on Africa is scarcely adequate in view of the importance of iron-working in that continent and the amount of information about it which has been collected in recent years; and more attention might well have been given to China and Japan. Dr. Friend has not omitted to mention the interesting religious beliefs and superstitions which attach to iron, the avoidance of its use for ceremonial purposes, and the attribution of a magical character to the smith. A striking example to which he might perhaps have directed attention is found in the avoidance customs which affect the relations of the general population with the iron-working tribes who are responsible for the supply of weapons in certain parts of East Africa; while in England, in addition to Wayland the smith, we have a good example of the smith-magician in that curious folk-song of the "Coal-Black Smith." Nor does he allude to the significant variant of the 'fairy-wife' folk-tale, once current in

Wales, and elsewhere, in which the wife vanishes when struck by iron.

As Dr. Friend does not confine himself entirely to the subject of iron, it may not be out of place to allude to one or two points in connexion with copper. The statement is repeated that Africa, excepting Egypt, had no copper and bronze age but passed directly from stone to iron. No doubt this is true generally; but no mention is made of the vast amount of copper which has been taken from the ancient workings in Rhodesia and the Katanga. Even now in Rhodesia the natives smelt copper in primitive furnaces. What was the destination of all the copper from these early workings, which has been estimated at an enormous number of tons? It is urgently necessary that the dumps at the ancient mines should be examined for evidence of date before they disappear in the course of the mining operations of to-day. A committee of the British Association has been appointed with the view of following up clues furnished by objects which have come into the possession of the mining companies; but whether anything can be done must depend to a great extent on the possibility of raising funds for the prosecution of inquiries on the spot.

Another curious point arises in connexion with the water-clocks in the form of a perforated bronze bowl which have been found at Wookey Hole and elsewhere. Dr. Friend is of the opinion that they are a British invention, although they occur in India and Ceylon presumably at a later date. Apparently he is not aware that they occur in Algeria also. What adds to the interest of this fact, but by no means makes it easier to explain, is that there also occurs in Algeria a primitive form of lathe which is identical in form with the lathe used in the peasant cottage-industry of wood-turning in Buckinghamshire.

The New Thermodynamics.

The New Heat Theorem: its Foundations in Theory and Experiment. By Prof. W. Nernst. Translated from the second German edition by Dr. Guy Barr. Pp. xvi+281. (London: Methuen and Co., Ltd., 1926.) 12*s*. 6*d*. net.

ONE of the most important branches of thermodynamics as applied to chemistry is the relation of heat of reaction with chemical equilibrium data and the calculation of the effect of temperature on the equilibrium constant. The fundamental equation here is that first deduced in its present form by van 't Hoff in 1884:

$$d \log_e K / dT = Q/RT^2,$$

where K is the equilibrium constant, Q the heat of reaction, T the absolute temperature, and R the gas constant. The effect of temperature on Q was known previously in the relation deduced by Kirchhoff, and special cases of the above equation had been used by Horstmann, Gibbs, and others. This is a differential equation, and its integration necessarily introduces an arbitrary constant, the value of which could be found only by experiment. It is the discovery of Nernst, published in 1906, and generally known as Nernst's theorem, which enables one in many cases to find the integration constant without any information as to the states of equilibrium. This is the practical aspect of the theorem, and it will be realised that it opens out important fields of application both in the laboratory and in industry.

In the shape used by Nernst, the maximum work, or diminution of available energy, is correlated with the heat of reaction in a form which is a consequence of van 't Hoff's equation, but Planck has shown that the content of the theorem can also be expressed in the statement that the entropy of every pure solid substance vanishes at the absolute zero. The entropy has been related to molecular statistics by Boltmann, Gibbs, and Planck, and in this field the quantum theory has found its place. It is therefore clear that an entirely new branch of the theory of heat has been created in recent years, and it is possible to speak of the 'New Thermodynamics' as distinguished from the classical science evolved from the work of Joule and Carnot by Lord Kelvin, Clausius, and others.

The book under notice is Prof. Nernst's own version of the new theory and of the experiments which have gone so far towards its verification. It is written in the style associated with its author; there is nothing superfluous and the mathematical apparatus is kept in its proper place. The translation has conveyed the spirit as well as the content of the original extremely well, and the book is one which ought to be a welcome addition to the library of every chemist who has occasion to make use of physical-chemical methods. It must be emphasised that Nernst's theorem has important industrial applications, and that the book is one which will be found intelligible by readers who have only a moderate knowledge of mathematics.

The first part of the book deals with the specific heats of solids and gases, and the experiments which showed that at very low temperatures the specific heats of solids become very small. It was this result which gave such an important confirmation to the quantum theory as applied to material systems. The theory in the case of gases is much less complete, and there is a comparative lack of experimental data in this field. In Chap. vi. the formulation of the new theorem is dealt with, in a direct and practical manner, and then follows an attempt to explain its physical basis, which is said to be contained in the law that "there cannot be any process taking place in finite dimensions by means of which a body can be cooled to the absolute zero." Important mathematical formulæ used in the applications of the theorem are next summarised, and then the application of the theorem to numerous cases follows in the rest of the book. Complete numerical data, curves, and references to the literature are given.

Perhaps the most interesting part of the book, from the theoretical point of view, is that dealing with the calculation of the chemical constants, which, together with thermal data, are required in the applications of the theorem. It cannot be said that this branch of the subject is yet in a very advanced state, but sufficient is given to enable the reader to understand the nature of the problem to be solved. J. R. P.

Our Bookshelf.

The Importance of Diet in relation to Health. (The People's League of Health Lectures.) Pp. xii + 130. (London: George Routledge and Sons, Ltd., 1926.) 3*s.* 6*d.* net.

THE subject matter of this book consists of a course of six lectures entitled "What to Eat and Why," given, under the auspices of the People's League of Health, by a distinguished group of lecturers.

In the first lecture, on "The General Principles of Diet," Prof. Leonard Hill points out the importance of diet, sunshine, and open air in the prevention of tuberculosis and rickets. Overfeeding is stressed as being the most general error, caused by the temptation of "the arts of cooking, by pastry cooks and sweet shops." "More people are probably killed off too early by intemperance in eating than by alcoholic intemperance." The food requirements of different classes of individuals are given, and the use and misuse of some of the commoner articles of diet are discussed. The second lecture, on "The Food of Mankind treated Historically and Geographically," by Sir D'Arcy Power, affords an extremely fascinating picture of the habits that have prevailed from the earliest times. The customs of the Egyptian, Grecian, and Roman Empires are compared with those of Anglo-Saxon and Norman times, showing the evolution of present-day usages. The chapter draws an important lesson, showing the relationship of moderation in food to health and character.

Prof. W. D. Halliburton's lecture on "Vitamins and the Diseases caused by Badly Chosen Diet" urges the importance of milk, green vegetables, and whole-meal bread. Many will endorse the lecturer's remark: "Cursed be he who removes his neighbour's landmark, and those who interfere with their neighbours' food ought to be equally banned." But Prof. Halliburton's remark that "It is the poor, whose ignorance leads them to suppose that white bread is the best and whose poverty compels them to eat the cheapest fat," is especially poignant, as we see from the previous lecture that throughout the ages the poorer classes have invariably endeavoured to follow the habits of the more well-to-do.

Dr. H. Scurfield follows with the application of the points already discussed to "Infant Feeding." The figures he has to give concerning the decrease of infant mortality in Great Britain are encouraging and compare favourably with progress made abroad. Dr. M. J. Rowlands explains the importance of "The Feeding and Breeding of Cattle in Relation to the Health of the People." It is pointed out that as vitamins are of vegetable origin, they must be liberally supplied to the cow if the milk is to be of proper quality. This is frequently overlooked, especially in winter feeding. Besides reducing the quality of the milk, the lecturer considers that neglect of these substances is the main cause of bovine tuberculosis. The last lecture, on "Food Preservation and Adulteration," by Prof. W. E. Dixon, is comforting, for he shows clearly that the addition of preservatives is unnecessary for all foods except sausages. Australia and New Zealand send butter to the United States, where added preservatives are absolutely forbidden, so they can quite easily provide us with the same quality.

The whole book is extremely readable and interesting, and should be widely studied by those interested in welfare work.

Acoma, the Sky City: a Study in Pueblo-Indian History and Civilisation. By Mrs. William T. Sedgwick. Pp. xiii + 314 + 33 plates. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1926.) 18*s.* 6*d.* net.

ACOMA, a pueblo stronghold of the Keres people of New Mexico, has a double claim on the interest of the student. Its inhabitants, now about five hundred in number, are the least known, the most reticent, and the most inscrutable, of the Indians of the pueblo area. Their history as told in the stories of the conquistadors, the poems of Villagrá, and later records, embodies examples of valour and endurance as striking as any in the history of the Spanish conquest of America. Mrs. Sedgwick has a thrilling story to tell—from the entry of the Spaniards into New Mexico in 1539 and the expedition under Coronado in 1540, when they first saw Acoma, until the final crushing of revolt among the inhabitants of that pueblo in 1699. To the Indians it seemed well-nigh impregnable, as indeed it appears to-day, and its capture was a remarkable feat of arms.

In culture the Acomas are akin to the Zuñi; but even that indefatigable and sympathetic inquirer, Mrs. Elsie Clews Parsons, was to a great extent baffled by the difficulties of obtaining information from them. To give a more or less coherent account of their beliefs and organisation, Mrs. Sedgwick has made use of the analogies of closely related cultures, but only with good reason. In this matter her judgment and her experience among the people themselves may be trusted. Although her account of the Acoma culture is not based entirely or even to a great extent upon first-hand observation, she has done a service both to the student and the general reader in presenting the historical and the anthropological material in an eminently readable form within the covers of one book.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Aurora of October 15, 1926, in Norway and Sounds Associated with It.

SOME curious phenomena accompanying the splendid aurora of Oct. 15, 1926, were observed by me. On the night in question I was working as observer of international determinations of longitude at the top of a hill named Voxenaasen in the neighbourhood of Oslo (approximate altitude, 470 metres). I was at work in a field observatory with a transit instrument registering star transits and chronometer beats for time determinations, when an initial aurora attracted my attention. My assistant was Mr. G. Jelstrup, electrotechnical student.

I was able, during intervals between my observations of time and polar stars, to observe the aurora, which was certainly one of the most splendid I had ever seen. But what is of preponderant interest is the following fact: When, with my assistant, at $19^h\ 15^m$ Greenwich Civil Time, I went out of the observatory to observe the aurora, the latter seemed to be at its maximum: Yellow-green and fan-shaped, it undulated above, from zenith downwards—*and at the same time both of us noticed a very curious faint whistling sound distinctly undulatory, which seemed to follow exactly the vibrations of the aurora.*

The sound was first noticed by me, and upon asking my assistant if he could hear anything, he answered that he noticed a curious increasing and decreasing whistling sound. We heard the sound during the ten minutes we were able to stay outside the observatory, before continuing our observations.

From $20^h\ 1^m$ to $20^h\ 6^m$ (Greenwich Civil Time) we registered on our radio-receiving set the rhythmic time-signals from the LY station (Bordeaux). We secured the whole series of tops—but at the same time the 'aurora statics' disturbed the pen of the registering instrument. The impulses thus registered are of varying strength, and each of them is of course exceptionally well determined in time, being 'received' at the same time as the scientific *time signals*. I therefore think that they may be of some interest. The maximum impulses of 'aurora statics' and their duration were:

No	Greenwich Civil Time.	Duration.
1	$20^h\ 4^m\ 28^s{\cdot}60$	$0^s{\cdot}08$
2	$20^h\ 4^m\ 29^s{\cdot}49$	$0^s{\cdot}10$
3	$20^h\ 4^m\ 39^s{\cdot}90$	$0^s{\cdot}25$
4	$20^h\ 4^m\ 40^s{\cdot}50$	$0^s{\cdot}25$

As regards the intensity of these impulses, I find that in each case the vertical component was greater than 100 microvolt/metre.

When, after the reception of the time signals, we again went out of the observatory, the curious sound had absolutely ceased, and later in the night, when also the aurora had vanished, we noticed that the atmosphere was as if swept clean from statics and disturbances of our wave-length.

Concerning the curious sound, I would only remark that the weather was absolutely calm when it was heard. As regards our antennæ system, it may be said that it consists of 5 strands of 40 metres each. Our receiver set is an aggregate, consisting of a three-circuits tuner, two high-frequency valves, one modulator, one heterodyne, four low-frequency valves, relay and chronograph.

HANS S. JELSTRUP,
Astronomer to the Norwegian
Geographical Survey.

Oslo (Norway), Dec. 1, 1926.

To the above most interesting communication from M. Jelstrup I may add the following:

On Oct. 15 I had the aurora stations at Bygdo, Oslo, Oscarsborg, Tomte, and Kongsberg in action from about 18^h Greenwich Civil Time to about 2^h on the following morning, and photographs were taken all the time from single stations, and from two or three stations simultaneously. About 70 successful photograms for the determination of height were secured.

Only a few of these have as yet been measured and calculated, and they show the ordinary heights of the aurora, from 90 kilometres to more than 400 kilometres. Fig. 1 shows one of the best photographs of curtains at $19^h\ 5^m\ 46^s$, taken from Oslo to the west. The simultaneous photograph from Oscarsborg proves that the lower border of the left curtain was from 124 to 131 kilometres above the earth, the middle curtain from 103 to 114 kilometres, and of the right from 110 to 132 kilometres.

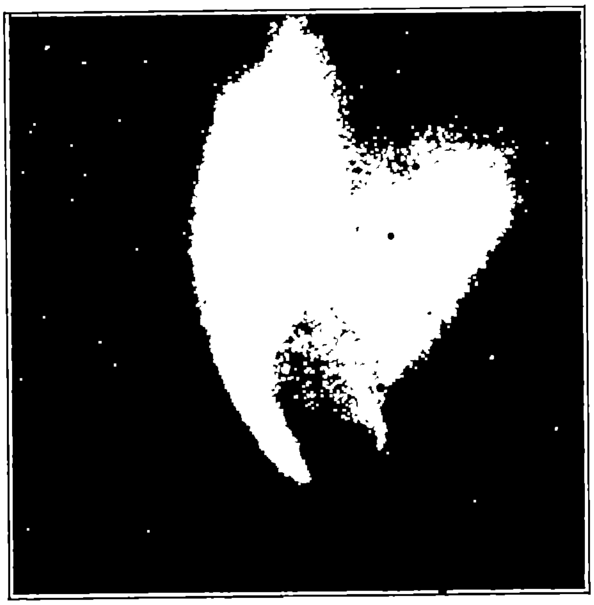

FIG. 1.—Aurora curtains photographed on Oct. 15.

During the period from $19^h\ 15^m$ to $19^h\ 25^m$ when M. Jelstrup heard the whistling of the aurora, I regret that no successful photograms were taken. From the visual observations made simultaneously at Bygdo by the meteorologist Rostad, who helped me during the work, I quote the following:

$19^h\ 10^m$. Dense masses of rays and curtains down to the horizon in E. and S.E.

$19^h\ 12^m$. The same down to the horizon in W., to the polar star in N., to the horizon in E., and down to 40° over the horizon in S.

$19^h\ 14^m$. The same to the Great Bear in N.

$19^h\ 16^m$. The same in the N. and S. down to 15° over the horizon. Red in S.

$19^h\ 21^m$. Strong diffuse arc through Can. venat. from the horizon in N.W. to the horizon in N.E.

$19^h\ 24^m$. Pulsating aurora begins.

$19^{h}\ 26^{m}$. Strong pulsations over the whole heavens. Red in S.

During the radio signals mentioned by M. Jelstrup the following observations are noted:

$20^{h}\ 3^{m}$. The pulsations have ended. All over the heavens a diffuse light. In the pocket spectroscope the yellow-green auroral line could be seen everywhere, from the entire heavens, from the snow, and from everything which was illuminated by the diffuse aurora.

$20^{h}\ 9^{m}$. Some pulsating bundles of rays.

$20^{h}\ 12^{m}$. The pulsations stronger and rays begin to appear.

It seems to me probable that the sound which, as M. Jelstrup says, exactly followed the vibrations of the aurora, could not come directly from the latter but from the surroundings, trees, antennæ, and so on, and were caused by electrostatic discharges, which in their turn were caused by influence from the varying electrostatic charges of the aurora overhead.

CARL STØRMER.

Bygdö, Oslo,
Norway.

Clerk Maxwell and the Cavendish Laboratory.

OF all the notable contributions to the record of the Cavendish jubilee given in the issue of Dec. 18, perhaps the most interesting to many is the one by Sir Joseph Larmor on Clerk Maxwell; for it suggests the way in which his equations, like those of the writer himself, contained the germs of many future developments, and incidentally directs attention to a Royal Society abstract which was unfortunately omitted from Maxwell's "Collected Papers." It was customary at that period for the Royal Society to publish not only the complete paper in the *Phil. Trans.*, but a thorough abstract also in the *Proceedings*—a practice which, perhaps unfortunately, has been departed from. The abstract referred to appeared in Dec. 1864, and gave in concise form the substance of one of the most remarkable memoirs of last century, "A Dynamical Theory of the Electromagnetic Field."

The abstract is exceptionally clear and luminous, and I should judge was written by Clerk Maxwell with some enthusiasm. It is, as Larmor says, full of ideas which have survived and developed since, though they have been supplemented and for a time apparently replaced by relativity and quantum considerations. It is possible, however, that posterity will see in Maxwell's ideas of more than half a century ago rather more than we perceive now; just as we now see in Faraday's "Thoughts on Ray Vibrations" more than seemed likely at the time. In order to make that Maxwell abstract more readily accessible to the present generation, and on the Continent, I suggest that it might be reproduced in NATURE.[1]

I venture to think that mathematical physicists are often too satisfied with incorporating their ideas in a compact form, not in its fullness readily intelligible, and refrain from elaborating their full significance after anything like the same fashion as men of letters elaborate and discuss and attend in detail to the great utterances of the past. The novelty of Clerk Maxwell's views at that period is sufficiently demonstrated by the reception or non-reception of them by Lord Kelvin and by the great physicists of the Continent. They were never altogether overlooked in Great Britain, but not until they were clinched by Hertz did they make their way in Europe; and the present generation is so occupied with its own rapid advances that a reminder of the ideas held by a pioneer long before most of them were born might be opportune and serviceable.

Incidentally, I would put on record a mention of what will doubtless elsewhere be referred to, namely, the remarkable gathering of physicists at Cambridge in celebration of Sir J. J. Thomson's seventieth birthday; a gathering which, though partly of a domestic character, was a sign of the enthusiasm and prolific genius of our own times, and could not have been surpassed in any city or university of the world. Indeed, if an earthquake or other catastrophe had overwhelmed the room in which that meeting was held, on the evening of Dec. 18, the science of physics would have taken long to recover from an irretrievable loss. The world at large, and even the disciples of other branches of science, do not realise to the full the magnitude of the developments which are now going on, both in actual achievement and in luminous speculation. We live in a time of upheaval, for the ultimate result of which we may have to wait many years; but there was in that gathering an element of hope, in the large group of younger workers, many present, others referred to, who show no sign of resting from their labours or being satisfied with the consolidation of past achievement, but are actively engaged in following up clues and in applying their well-prepared minds to future and perhaps still more fertile discoveries.

OLIVER LODGE.

Dec. 21.

The Mystery of Money.

I DO not think the writer of the very full review published in NATURE (Nov. 27) of my book, "Wealth, Virtual Wealth and Debt," really understands my new theory of money or the solution of the economic paradox, which he states, surely rather prematurely and prophetically, will be rejected by every student of economics. After all, I suppose every student of chemistry rejected the theory of atomic disintegration when it was first proposed a quarter of a century ago.

The reviewer quotes me to the effect that the aggregate of money, *irrespective of its quantity*, represents the aggregate value of the wealth which the community prefers to be owed rather than to own—which negative quantity of wealth I term the *Virtual Wealth* of the community—and then states that the argument is not lucid, even to the trained student, especially when he reads on a later page that the virtual wealth has in fact little to do with the quantity of money. He alleges I do not seem to realise that people retain money balances for their convenience, although on p. 205 I state, "It suits some of the people's convenience and affairs all of the time and all of the people's some of the time to be owed rather than to possess wealth so that they may be at liberty to select at their own time the sort and quantity they need . . . in exchange for their money." Similarly, with regard to my proposals to issue national money in lieu of bank credit, ending with: "In truth, Prof. Soddy's real plea is for the nationalisation of banking," the criticism is a travesty of what I do propose and the 'real plea' about the last thing I would advocate.

As regards the new theory of money, it follows the ordinary quantity theory, familiar to every trained student, in regarding the value or purchasing power of the unit of money as being inversely proportional to the quantity in circulation, considered as a single independent variable. This is the same thing as saying, as I do, that the value of all of it is the same, whatever that all may be. I should have rather expected from the trained student and the economist the criticism that my new theory was a mere round-about and unnecessary re-enunciation of the old quantity theory, though they are in fact quite different. On my theory the value of the aggregate quantity of money is a negative non-existent quantity of wealth, not amenable to the laws of conservation, and alterable, though not very widely, by purely psychological factors. On the quantity theory it is related, in some indefinite and unexplained way, with the quantity of goods in existence, and, by what will I think come to be regarded as a very curious blunder, also with the velocity of circulation of money, although changes in the velocity of circulation affect equally rates of production and consumption and leave the quantity of goods in existence unchanged.

---

[1] We hope to be able to find space to reprint the abstract in an early issue.—ED. NATURE.

I can only deal in limited space with a few of the other criticisms. As regards the War inflation, I do not want "to put the clock back." The evils the country is now experiencing are the direct consequence of the attempt to put the clock back to pre-War as regards the value of money. I want for the future to stop all possibility of juggling with the value of the £ sterling as much as with that of the lb. avoirdupois. The reviewer states that my proposals would bring to the ground "the whole credit structure, with all the assistance it renders to industry." My object is absolutely to destroy the whole system of fictitious credit in which, not the lender, but the general public gives up what the borrower receives, paying the principal out of the purchasing power of the money they own, and the interest out of taxation, and to replace it by a system of genuine credit in which the lender gives up what the borrower receives. As for the "assistance" the existing system renders to industry, look around and meditate upon Cacus who dragged the oxen back into his den that it might appear he had let them out. Where else but in the so-called science of business would it be deemed unimportant who provided and gave up the money for a loan so long as it was provided?

The reviewer himself answers his own doubt as to how the £M2000 of new money to replace bank credit would be issued. "The new money would unquestionably be paid into the banks," who have "in future to keep pound for pound against" *current-account* "deposits." The money will continue to be, as it already is, in circulation by cheque. There is no addition to the quantity, but it is proposed to rectify the omission of the banks to pay the State for it when they issued it and put it into circulation. The 'penalisation' of holders of War Loan by the redemption of their stock is imaginary. The stock would be bought on the open market, and if they do not want to be 'penalised' they need not sell it.

I admit my proposals do not fully solve all the problems facing Great Britain in its excessive dependence on export trade for its food, and merely claim that they would make their solution easier rather than more difficult. The reviewer misrepresents me as advocating "floods of new currency . . . [being] issued by the State *pari passu* with the optimism of the producer" despite the absence of foreign buyers. Money is issued *pari passu* with increase of production to maintain the index number, or the *average* level of home prices, constant, and to keep them from falling with the increase of production. Goods unwanted and for which there are no buyers would fall in price, and the goods the buyers wanted would rise in price *relatively* as now. It is the average price-level which is maintained constant.

FREDERICK SODDY.

131 Banbury Road, Oxford.

IT is always unprofitable to both author and reviewer to attempt to reconcile conflicting views by further explanation on either side. Space alone precludes a successful issue. Such differences can only be left to the arbitrament of the reader. In this case he can clearly judge on the count of lucidity. A few further points may be within the limits of his patience.

Prof. Soddy's conception of "virtual wealth" is a phantasy. Every deposit in a bank is balanced by an asset, presumably of genuine value and backed by real goods or definite rights. These deposits constitute part of the aggregate quantity of money. The author contends in his letter that their value is a "negative non-existent quantity of wealth." Passing by the difficulties of determining how a quantity can be non-existent or how a value (connoting the abstract) can be a quantity (connoting the concrete), let the reader note that the review agreed (with the author) that the purchasing power created by bank loans is abstracted from the community, through the consequential reduction of the general purchasing power of money. Hence, if the borrower gains (temporarily and upon his undertaking ultimately to repay it to the bank) what the community loses, and if that loss is real—as Prof. Soddy truly argues—how can the gain, which is expressed quantitatively by the deposit created by the bank loan, be non-existent?

While accepting the author's statement that the nationalisation of banking is the last thing he would advocate, the reviewer still adheres to the opinion that it would be impracticable to give the State all the credit powers of the present banking system unless it also owned and conducted that system. The State is indeed contemplated (p. 198) as replacing the banks as a lender of £2,000,000,000.

Prof. Soddy urges that after the State has issued this amount of new currency, each bank when it lends in future is to give up what the borrower receives. We may start then with a simple balance sheet of:

STAGE 1.

Liabilities.		*Assets.*	
Capital . . .	£20	Cash	£120
A's Deposit . .	100		
	£120		£120

B, wishing to borrow £100, goes to the bank, which is to give up to him £100 cash. Let it do so. B spends the cash in buying, say, a house from C, and C deposits the cash in the bank. The balance sheet then appears:

STAGE 2.

Liabilities.		*Assets.*	
Capital . . .	£20	Cash	£120
A's Deposit . .	100	B's advance . .	100
C's Deposit . .	100		
	£220		£220

So the process goes on until the ratio of cash to deposits reaches the safe limit of 1 to x. How does this differ from the present system? Not one whit. But Prof. Soddy will retort that he has stipulated that the bank must keep pound for pound against deposits, so that stage 2 can never be reached. Exactly, and so the review stated that the banks can earn no interest, and that the whole credit structure would thereby be brought to the ground.

Lastly, does Prof. Soddy seriously consider that holdings of £2,000,000,000 of interest-bearing War Loan could be permanently cancelled by its purchase on the open market in exchange for 'new national money' issued by the State, such money bearing no interest at all? If so, he has yet much to learn of human nature. W. H. Coates.

Transmission of Excitation in Plants.

In his letter in Nature of October 23, Prof. N. G. Ball throws doubts upon the validity of my conclusions that in Mimosa (1) the transpiration-current has nothing to do with the conduction of the excitatory impulse, and (2) that the conduction is a phenomenon of propagation of protoplasmic excitation. I would refer Prof. Ball to my work "The Nervous Mechanism of Plants" (1926) for accounts of experimental demonstrations fully justifying the above conclusions. Limited space available allows me to refer here only to a few of the more important results.

The possibility of stimulating Mimosa by application of extracts of the stem to the basal end of a cut shoot has been adduced as evidence in support of the transpiration-current theory. This is by no means conclusive, as I have already pointed out in "The Nervous Mechanism of Plants," p. 17: "It is conceivable that certain vegetable extracts might act as stimulants; vegetable alkaloids of a poisonous nature, for example, produce excitation when applied in minute doses to the cut end of the stem. It would, however, be quite unreasonable to conclude from the result that an alkaloid is excreted from the plant under the action of a minimally effective stimulus." The following facts will be found to discredit the theory of transpiration-current.

1. The transpiration-current theory is based on the supposition that injury to wood caused by the wound, produces a stimulating substance which, being carried by the transpiration-current to the leaf, stimulates it to movement. It follows from this theory (*a*) that an intense wound-stimulus is essential for stimulation; (*b*) that the impulse should only travel upwards in the same direction as the ascent of sap; (*c*) that the velocity of the transpiration-current should be the same as that of the excitatory impulse; and (*d*) that in conditions where there can be no ascent of sap there should be no transmission of impulse.

I will take these points one by one. (*a*) I have shown that Mimosa can be excited by an electric shock one-tenth of the intensity of that which evokes human sensation. No wound is produced, yet the excitation produced by such an excessively feeble stimulus is transmitted to a considerable distance. (*b*) The excitation is found to be *simultaneously conducted both upwards and downwards*. It is also found that, under moderate unilateral stimulation, *the transmitted excitation ascends along one side of the stem to the apex and descends down the other*. The transpiration-current could not possibly have produced this result. (*c*) Accurate determinations of the velocities show that the rate of transmission of excitation is several hundred times quicker than that of the ascent of sap. (*d*) The tip of the uppermost leaf of Mimosa was stimulated by the application of a drop of hydrochloric acid: an impulse was generated which travelled to a considerable distance downwards against the direction of the normal ascent of sap. Subsequent chemical examination proved that the stimulant had not been transported, but had remained localised at the point of application.

These experimental results leave no doubt of the unfounded character of the transpiration-current theory. Nor can this theory be considered to have established its claim to acceptance until it has been demonstrated that excitation induced not by flame alone, but by stimulus of every kind—chemical, mechanical, electrical—is transmitted across the water-gap in the fundamental experiment upon which the theory has been built.

2. I next adduce positive evidence which proves that the transmission in the plant is one of protoplasmic excitation. This is demonstrated by the fact that the transmission is correspondingly modified by all conditions which modify the transmission of excitation in the animal nerve. The polar action of a constant electric current is identical in the two cases; when the current is feeble, stimulation occurs at cathode-make, the excitation being transmitted to a distance; with stronger current, excitation is produced at cathode-make and at anode-break. In both Mimosa and animal nerve, the velocity of transmission is increased within limits by a rise of temperature, and diminished by a fall. In both, transmission may be arrested temporarily or permanently by various physiological blocks. When the conducting tissue in the animal or plant is cooled, the speed of the impulse is slowed down, culminating in its arrest. The conducting power is temporarily arrested by a block produced by the passage of an electric current in a portion of the conducting tissue through which the impulse is being transmitted. This electrotonic block is removed on the stoppage of the current. Finally, poisonous solutions abolish the conducting power of both animal and plant.

These results offer conclusive proof that the conduction in the plant is a phenomenon of propagation of protoplasmic excitation, as in the nerve of the animal. J. C. Bose.

The Behaviour of Cultures of *Leishmania tropica*, *L. infantum*, and *L. braziliense* in the Sandfly, *Phlebotomus papatasii*.

Experiments were carried out to determine the behaviour of *Leishmania braziliense* and *L. infantum* in *P. papatasii*. The sandflies were infected by feeding through a membrane of rabbit skin on emulsions of flagellates in inactivated rabbit serum or defibrinated rabbit blood, and control experiments were performed with *L. tropica* in sandflies similarly infected.

L. tropica from cultures introduced into the sandfly *P. papatasii* (irrespective of the age and source of the strain of *L. tropica*) behaved exactly as *L. tropica* ingested by the sandfly from oriental sores, *i.e.* infection was always present in the uppermost end of the cardia, and in two cases out of twenty, flagellates were also found in the pharynx. Further, in cases of light infections the flagellates were confined to the uppermost part of the cardia only and, in some cases, sandflies which had fed on an emulsion of 100·000 flagellates per c.mm. were found to contain no flagellates at all. Passage of *L. tropica* from cultures through *P. papatasii* appears to increase the pathogenicity for man of the organism, as the following experiment shows.

A subculture made on August 27 from a culture taken directly on July 7 from an experimental human lesion was used for the experiment. September 15, Sandfly No. 172 (hatched in laboratory, September 15) *P. papatasii* ♀ fed on emulsion of culture (100·000 per c.mm.) September 26: Sandfly died and was dissected. Numerous flagellates were found in the midgut, particularly in the uppermost part of the cardia, which was almost completely choked up by flagellates. The majority of the flagellates were long free forms. The stomach of the sandfly was inoculated into a scarified point on the right forearm of a volunteer. At the same time, flagellates from the same culture on which the sandfly fed were inoculated into two scarified points on the left forearm of the same volunteer.

Result—November 1: Leishman-Donovan bodies were found in a papule on the right forearm on the site of the inoculation with material from the sandfly.

Nothing has so far (November 16) been observed on the sites inoculated with flagellates from culture.

Leishmania infantum and *L. brasiliense* ingested by sandflies (*P. papatasii*) from emulsions of flagellates behaved quite differently from *L. tropica*. Although active division and, in the case of *L. brasiliense*, marked morphological changes occurred in the sandfly (development of short stumpy forms into long and thin forms and exflagellation of Leishman-Donovan bodies), the flagellates were confined to the stomach, and, in two cases out of twenty in *L. brasiliense*, flagellates were also found in the lowest part of the cardia. In no case were the flagellates found in the uppermost part of the cardia in the neighbourhood of the œsophageal valve, nor were any forms found attached to the epithelium.

The researches of the Indian Kala-azar Commission on the development of *Leishmania donovani* in *Phlebotomus argentipes* and our own observations on the development of *L. tropica* in *P. papatasii* tend to show that the sandfly in which flagellates of a species of Leishmania are found attached to the epithelium and free in the uppermost part of the cardia is the carrier of that species of Leishmania, *e.g. P. papatasii* is a carrier of *L. tropica* and *P. argentipes* is a carrier of *L. donovani*.

Should the above observations be repeated with recently isolated strains of *L. infantum* (infantile leishmaniasis is absent from Palestine) there would be very strong evidence to the effect that *P. papatasii* is not the carrier of *L. infantum*, and the carrier of this parasite is to be sought in *P. perniciosus*, *P. sergenti*, or a member of the *minutus* group of the genus Phlebotomus. The fact that cultures of *L. tropica* behave exactly as ingested Leishman-Donovan bodies in *P. papatasii* is important, for it suggests that the simple and rapid process of observing the behaviour of cultures of a given species of Leishmania in sandflies may be used for determining which Phlebotomus sp. is the transmitter of that particular species of Leishmania.

The Origin of Fatuoids in Cultivated Oats.

The sudden appearance of fatuoids, that is, forms resembling the wild oat *Avena fatua*, in varieties of the cultivated oat *A. sativa*, has for many years attracted much attention both by its genetic interest and agricultural importance. The opinion has been widely held that they originate through natural crossing between *A. sativa* and *A. fatua*, but in recent years they have been more generally regarded as simple loss mutations from *A. sativa*. The heterozygous form, which is intermediate between the normal and the fully developed fatuoid, usually appears first, and in nearly all cases previously recorded these heterozygotes segregate normals, heterozygotes, and fatuoids in a ratio of approximately 1 : 2 : 1.

A combined genetical and cytological study of this problem, begun early in 1924, has revealed many new and interesting features. Not only have three, or possibly four, different types of heterozygous fatuoids been discovered, thus bringing the problem closely into line with the speltoid problem of cultivated wheat, but distinctive chromosome conditions have also been found to be correlated with the genetic behaviour and with the character of the segregates in the different types. The first and most common type, giving the 1 : 2 : 1 ratio of normals, heterozygotes, and fatuoids, has been described in Nature, 115, 677-678, 1925, and *Scientific Agriculture*, 6, 303-313, 1926. Briefly, all the segregates are of approximately equal vigour, and all have the normal number of chromosomes, namely, forty-two; but while in the normals these form twenty-one bivalents, in the heterozygotes the arrangement is frequently nineteen bivalents, one trivalent, and one univalent, and in the fatuoids it is often nineteen bivalents and one quadrivalent.

The second type also gives a ratio of approximately 1 : 2 : 1, though the numbers so far obtained are too small to determine this exactly, but the fatuoid segregates from it are all dwarfed and partially sterile. In this case the normal segregates again have twenty-one bivalent chromosomes. The heterozygotes, however, have an extra chromosome, and their complement is either twenty-one bivalents and one univalent, or twenty bivalents and one trivalent. The dwarf fatuoids in this type have two extra chromosomes, the total of forty-four being arranged usually as twenty bivalents and one quadrivalent.

Normals and heterozygotes are segregated in approximately equal numbers by heterozygous fatuoids of the third type. The fully developed fatuoid form appears only very rarely, and is always dwarf and sterile. The normal segregates, again, have the normal twenty-one bivalents. The heterozygotes, however, have lost one chromosome and have only nineteen bivalents and one univalent. The sterile dwarf fatuoids have completely irregular meiotic divisions, including faulty pairing, and their total chromosome number is only forty.

The fourth type has arisen from the third, and is similar to it except that the heterozygous segregates are much more numerous than the normals, the ratio being about 5 : 1. In four heterozygous plants of this type which have been cytologically studied, the chromosome number is forty-one, as in heterozygotes of the third type. Certain differences in the chromosome behaviour, such as the more frequent formation of trivalents and the lagging of one or two bivalents, have been observed, but until the genetical constitution of the particular plants has been determined, it is impossible to say whether these minor differences have any special significance.

The close correlation between cytological conditions and genetic behaviour in these different types of fatuoids seems to indicate clearly that fatuoids arise from normal oats, not by either gene mutation or natural crossing, but by any one of several different chromosomal irregularities, which upset the normal chromosome balance and permit the expression of other characters.

Discussion of the particular hypotheses which best fits the observations must be left for the full account of this work, which will shortly be prepared.

On the practical agricultural side there has emerged the possibility of developing commercially valuable varieties of oats which are entirely free from fatuoid factors.

X-ray Evidence for the Existence of Different Modifications of Fatty Acids.

In continuation of the work on the high order X-ray reflections of fatty acids done in this laboratory (J. A. Prins and D. Coster, Nature, July 17, 1926), I tried to get the high orders with stearic acid. In determining the long spacing of a crystal of stearic acid obtained by slow crystallisation from acetone, I found the remarkable fact that the crystal showed a long spacing of 43·95 A.U., whereas a thin layer obtained by melting the acid on a glass strip gave a spacing of 39·75 A.U. Crystals obtained from alcohol and petrol also showed the larger-spacing. A film obtained by evaporating an alcoholic solution on a glass strip gave the smaller spacing, but an acetonic film gave the two spacings, the relative intensities of which were altered by slight changes in the way of forming the film. Apparently these facts point at the existence of different modifications of stearic acid.[1]

As, on the other hand, Garner, Randall and Ryder (*Jour. Chem. Soc.*, 125, 881, 1924; 127, 720, 1925), from a determination of the heat of crystallisation and molecular volume, concluded that undecoic acid exists in two enantiotropic modifications, it seemed worth while to test this point by an X-ray investigation. According to Garner (*loc. cit.*) the transition takes place between 12·5° C. and 17° C. I determined, therefore, the long spacing of a layer of undecoic acid obtained by melting on a glass strip, first at 20° C. and a second time at 12·5° C. the apparatus not being changed between the two exposures (the lower temperature was obtained simply by opening the windows). At the higher temperature a spacing of 25·4 A.U. was found, which spacing has already been measured by Müller and Shearer (*Jour. Chem. Soc.*, 123, 3156, 1923). At the lower temperature, however, these lines had practically disappeared and another set of lines of strong intensity occurred on the plate, these lines belonging to a spacing of 30·1 A.U. When the temperature was raised again to 20° C. and a photograph was taken after some hours, the lines due to the longer spacing, though not wholly disappeared, were much fainter, whereas the intensity of the lines belonging to the smaller spacing had much increased. These facts give a strong support to the view suggested by Garner and his collaborators.

After these results were obtained the beautiful work of Piper, Malkin and Austin (*Jour. Chem. Soc.*, Sept. 1926) on the different modifications of the even fatty acids came to my notice. As is stated by these authors, the different spacings of stearic acid seem to be independent of the temperature, and only to depend on the manner the reflecting layer is obtained.

The higher orders are now being investigated in order to get some information about the molecular structure of the different modifications.

I am much indebted to the kindness of Prof. P. E. Verkade of Rotterdam, who put a quantity of very pure undecoic acid at my disposal.

A Rock of Unknown Origin from Glacial Gravel at Ipswich.

A little time ago I found, in the sub-Chalky Boulder Clay glacial gravel, exposed in the brickfield of Messrs. A. Bolton and Co., Ltd., to the north of Ipswich, an erratic of unusual and arresting appearance. The gravel in which the specimen was embedded is that which, in my opinion, was laid down in the interval of time between the deposition of the Kimmeridgian Chalky Boulder Clay and that of the Upper Chalky Boulder Clay of East Anglia. As I had never before seen a rock in the Ipswich area of the type discovered, I submitted it to Prof. P. G. H. Boswell, of the University of Liverpool, and to Dr. Herbert H. Thomas, of the Geological Survey, for investigation. Both these experts, though giving me valuable information upon the nature of the erratic, were unable to inform me as to its probable source of origin, and Dr. Thomas, suggesting that this source might be in some area of old rocks, such as Scandinavia, advised me to submit the specimen to Prof. Victor Goldschmidt, of Oslo. This I have now done, and with Prof. Goldschmidt's permission, I give below the result of his examination of the rock.

"I have got your specimen, and I have examined it. If the boulder has its place of origin in Norway, it must be a sandstone from one of the pre-Cambrian formations. The rock is a breccia, consisting of fragments of a sandstone rock in a matrix. The sandstone of the fragments is without any doubt a sedimentary rock, containing well-rounded grains of quartz. The matrix is rather fine-grained; the matrix contains perhaps even pyroclastic material, but that could not be ascertained. The clastic grains of the matrix are angular. One may say that none of the Eocambrian, Cambrian, or other Palæozoic sandstones of Norway has any resemblance to your specimen. Among the pre-Cambrian formations there might be several possibilities for placing the boulder. It is most likely that it may be derived from the pre-Cambrian Telemark formation, which, among other rocks also includes quartzitic sandstones, breccias, and also pyroclastics. The general character of the rock, its degree of re-crystallisation, makes it possible, but of course not certain, that it is derived from the districts around the mountain Gausta in Telemarken. My friend, Prof. J. Schetelig, to whom I showed your boulder, also agrees with me. But neither of us has ever seen exactly the same rock *in situ*. We shall look for it in Telemarken. I shall send the boulder back to your address by mail to-morrow. The thin section I shall keep here, to have a possibility to identify the boulder, if I succeed in finding the breccia *in situ*."

I would wish to thank Profs. Boswell and Goldschmidt, and Dr. Thomas, for the help they have given me in this matter. The rock, which I have deposited in the Ipswich Museum, where it can be examined, is of a definite pinkish colour.

One House, Ipswich.

Thermal Agitation of Electricity in Conductors.

Ordinary electric conductors are sources of spontaneous fluctuations of voltage which can be measured with sufficiently sensitive instruments. This property of conductors appears to be the result of thermal agitation of the electric charges in the material of the conductor.

The effect has been observed and measured for various conductors, in the form of resistance units, by means of a vacuum tube amplifier terminated in a thermocouple. It manifests itself as a part of the phenomenon which is commonly called 'tube noise.' The part of the effect originating in the resistance gives rise to a mean square voltage fluctuation V^2 which is proportional to the value R of that resistance. The ratio V^2/R is independent of the nature or shape of the conductor, being the same for resistances of metal wire, graphite, thin metallic films, films of drawing ink, and strong or weak electrolytes. It does, however, depend on temperature and is proportional to the absolute temperature of the resistance. This dependence on temperature demonstrates that the component of the noise which is proportional to R comes from the conductor and not from the vacuum tube.

---

[1] Both lattice-constants have already been measured by Muller (*Jour. Chem. Soc.*, 123, 2043, 1923; Nature, 116, 45, 1925), but he seems not to have paid much attention to the discrepancy between these two results.

A similar phenomenon appears to have been observed and correctly interpreted in connexion with a *current sensitive* instrument, the string galvanometer (W. Einthoven, W. F. Einthoven, W. van der Horst, and H. Hirschfeld, *Physica*, 5, 358-360, No. 11/12, 1925). What is being measured in these cases is the effect upon the measuring device of continual shock excitation resulting from the random interchange of thermal energy and energy of electric potential or current in the conductor. Since the effect is the same for different conductors, it is evidently not dependent on the specific mechanism of conduction.

The amount and character of the observed noise depend upon the frequency-characteristic of the amplifier, as would be expected from experience with the small-shot effect. The apparent input power originating in the resistance is of the order 10^{-18} watt at room temperature. The corresponding output power is proportional to the area under the graph of *power amplification—frequency*, at least in the range of audio frequencies. The magnitude of the 'initial noise,' when the quietest tubes are used without input resistance, is about the same as that produced by a resistance of 5000 ohms at room temperature in the input circuit. For the technique of amplification, therefore, the effect means that the limit to the smallness of voltage which can be usefully amplified is often set not by the vacuum tube, but by the very matter of which electrical circuits are built.

Bell Telephone Laboratories, Inc.,
New York, N.Y., Nov. 17.

Oxygen = 17. Oϕ.

I KNOW that I am very ignorant, but old and unrepentant as I am I still live to learn from young people and watch their doings with delight, tho' maybe they are sometimes a little 'previous.' The argument behind Messrs. Harkins and Shadduck's letter (NATURE, December 18, p. 875) is doubtless irreproachable and unanswerable. Probably, therefore, I am more than stupid in being surprised at "the atom (presumably oxygen of mass 17) which is synthesised." Suppose, however, that a poor errant molecule of fair hydrone were the stricken 'atom,' it might well be 'electrolysed' and give OH = 17 + H = 1. Who will say me nay and make it clear that this cannot be? Uesanian orders are sometimes tall and the propinquity of the Wheat Pit may well have influenced the Chicago laboratory, just as Cambridge, being an apanage of Newmarket, is given over to racing competitions and so demoralises the whole of our educational system.

I know full well, that it is wrong for a poor worm of a chemist to turn and put a common or garden interpretation upon the work of august and fashionable physicists: that they should be regarded as kings who can do no wrong. I have, however, preserved from my youth the memory of a king who wore no clothes and myself still work a little in the garden with not too much regard for weather. NATURE, too, disturbs my belief in things. In it, Dr. Jeans—who, being senior secretary of the Royal Society, a mathematician and a man who sees stars, must know everything—has recently assured us that the elements short of uranium are infinitely stable, even at the super-satanic temperature of 12,500,000 million degrees. If so, is a mere missile of mass 4 with a range of 6 cm. likely to knock spots off them? Cannot we rather picture the nitrogen molecule, in itself a hard nut to crack, as contemptuously asking, whenever hit by an α-particle: 'Who are you shoving of?' and moving on its way, naked and unashamed, uncaressed by the particle—this latter, attended as it is from its birth by the faithful electron, as then wickedly compassing the prostitution of fair hydrone?

My faith in the immaculate judgment of the 'Physicals' would be greater if they would curb their imagination by learning just a little chemistry and would seek to tell me what happens when I rub my stylo upon my coat sleeve: a fundamental question to which I can get no answer. The α-particle may be doing as the moving stylo does. When I read the heroics in NATURE of December 18, I am only too conscious of the greatness of the 'Electronicals': still, men with the unlimited speculative power they possess might sometimes deign to deal with matters which affect ordinary mortals and with the common objects of the laboratory floor.

HENRY E. ARMSTRONG.

Temperature Coefficient of γ-Ray Absorption.

RECENT improvements in design and technique for a gold-leaf electrometer, details of which will be published shortly, have made it possible to apply the instrument with success to the problem of a possible temperature coefficient of γ-ray absorption. Preliminary measurements with lead as absorber, over a temperature range of about 250° C., indicate that when due allowance has been made for the expansion of the lead, there occurs an increase in the absorption coefficient of approximately 0·2 per cent. per hundred degrees rise of temperature. That the effect is dependent on temperature, or indeed on any incidental at all, is somewhat of a surprise; and considerable interest is added by the recent account by H. S. Read (*Phys. Rev.*, 27, p. 373, 1926) of an effect of temperature on X-ray absorption, in which he records, for lead and the five other metals examined, a temperature increase in the coefficient of the same magnitude as here reported. Further investigation is contemplated.

The Supposed Law of Flame Speeds.

WITH reference to Prof. Bone's letter in NATURE of Dec. 11, p. 837, it is evident that the speed generalisation advanced by Prof. R. V. Wheeler and Dr. W. Payman must break down when one of the combustible gases in a complex mixture interferes with the burning of another. This has been shown to occur for carbon monoxide–hydrogen–air mixtures by Dr. Payman (*J.C.S.*, 115, 1454, 1919). In this case the speed of burning of carbon monoxide is much increased in the presence of hydrogen. The reverse effect occurs when mixtures of carbon disulphide not too far removed from the limit are mixed with certain other combustibles (*J.C.S.*, 121, 2561, 1922). By mixing suitable carbon disulphide–air and (say) ether–air mixtures having the same speed of flame, mixtures can be obtained which refuse to propagate flame.

Saltcoats, Dec. 20.

Popular Long-Range Weather Forecasts.

SINCE last April, forecasts of the weather for fifty days ahead have been appearing in the *Daily Mail*. The forecasts, which are prepared by Lord Dunboyne, have excited a considerable amount of interest. The question of long-range forecasts has been engaging the attention of meteorologists for some time, and they would welcome any progress in this direction, even if in the first instance the forecasts were purely empirical. Lord Dunboyne has not published any account of the principles he uses, and it is not possible therefore to study the methods of the forecasts, but only the results obtained. The forecasts are given in the form of a diagram, and it is stated in the explanation that the higher the curve rises above a datum line the greater the probability of rain, and the lower the curve falls the greater the probability of dry weather. When the curve rises sufficiently far above the datum line, and rainy weather is indicated, the area within the curve is blackened, and similarly the lower parts of the diagram are shaded to indicate that dry weather is forecast.[1] In this way the periods when wet or dry weather is expected are shown at a glance.

From the curves it is possible to read off what are here called 'forecast numbers.' The day when the curve is below the datum line has a forecast number of 1; one with a curve on the datum line a forecast number of 2; a little above gives 3; considerably above the datum line but not up to a blackened area, 4, and when the curve rises to the blackened area the forecast number is 5. To compare the forecasts with the actual weather, readings have been taken from the *Daily Weather Report* from which weather numbers have been deduced. The weather number for each day is determined as follows: 5 is a day when more than 2 mm. of rain has occurred; 4 when the rainfall is between 0·2 mm. and 2 mm.; the other numbers are for days when the rainfall is less than 0·2 mm.; 3 is a day when the mean cloud amount is 8 or more; 2 when the mean cloud is between 3 and 7·9, and 1 when the mean cloud is 0 to 2·9. These cloud amounts are the means of the cloud amounts recorded at 9 A.M., 1 P.M., and 6 P.M. This seems to be a fair way of comparing the two sets of numbers. The only doubtful case is that of weather number 3, which represents overcast skies, for anticyclonic cloud may cover the sky in perfectly dry weather, and it would be unfair to class a forecast number of 1 as a failure, when the weather that occurred was anticyclonic, merely because the sky was overcast. But such weather, though it occurs in the winter, is not much in evidence in the summer, and the period under consideration is that from April to October; during this part of the year an overcast sky may very fairly be taken as half-way between rainy and dry weather, and the above criticism would not apply.

The diagrams are given for fifty days ahead, but they are amended from time to time, and therefore the forecast for a given week made six weeks ahead may differ from the forecast for the same week as given five, four, or less weeks ahead. To take, for example, the forecast for south-east England for the week commencing July 4 (Fig. 1). When this first appears in the *Daily Mail* for May 28 it shows the curve below the datum line for all the days except July 5 and 10, on which days the curve rises just above the datum line; that is to say, the forecast was for a week with a definite but small probability of fine weather. The next forecast for the same week shows the curve above the datum line for all days with a probability of rain on July 5 and 7; this probability seems to be reduced in the next diagram, and when we come to the forecast for three weeks ahead the curve has fallen below the datum line again except at the end of the week, when it rises a little above; for two weeks ahead a blackened area occurs on the last day, and the forecast for one week ahead is very similar. The actual weather experienced at Kew was as follows:

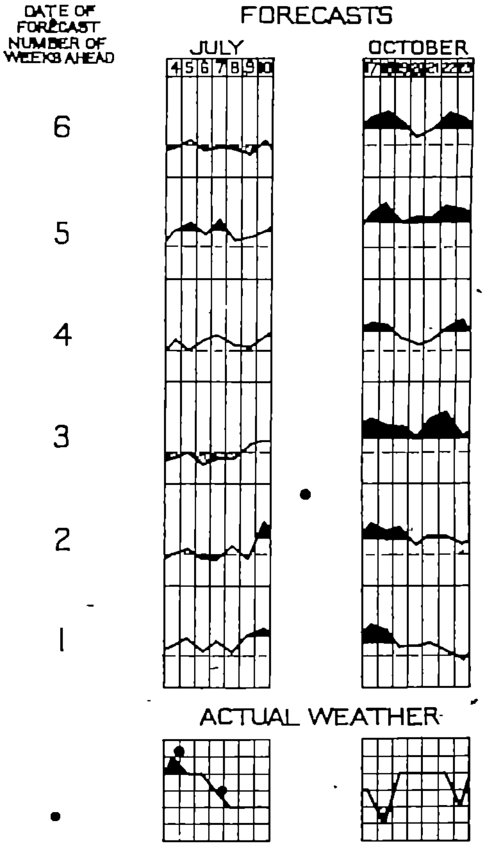

FIG. 1.

Date.	Rainfall.	Weather Number.
July 4 . .	5·0	5
,, 5 . .	2·0	4
,, 6 . .	0·6	4
,, 7 . .	Trace	3
,, 8 . .	..	2
,, 9 . .	Trace	2
,, 10 . .	Trace	2

Another week, that commencing October 17 (Fig. 1), when it first appeared in the *Daily Mail* for September 10, gave rain as probable at the beginning and end of the week, on all days, in fact, except September 20 and 21, but the curve was above the datum line for the whole week; the next curve was above the blackened area all the week. The forecast for four weeks ahead was very similar to the first one, but the blackened areas were reduced. The forecast for three weeks ahead had the curve again above the blackened area all the week. The next two charts kept the blackened area at the beginning of the week, but the curve fell lower at the end of the week, and in the last forecast of the series it was below the datum line on the last day of the week. The following was the actual weather at Kew:

---

[1] Some slight changes have lately been made in the diagrams, but this does not affect what follows.

Date		Rainfall.	Weather Number.
Oct. 17	. .	..	3
,, 18	. .	Trace	1
,, 19	. .	0·3	4
,, 20	. .	0·3	4
,, 21	. .	1·0	4
,, 22	. .	1·1	4
,, 23	. .	0·1	2

These weeks were taken at random, without first looking up the actual weather that occurred, and without trying to find a case where successive forecasts differed among themselves. There are other examples where still more striking changes occurred in successive forecasts for the same week, changes much greater than would be expected from the statement that "the curves are subject to slight amendment as time advances." So little concordant with each other are the successive forecasts for the same week that it is evident that, whatever value the forecasts may have, six weeks is considerably too long a period for the methods employed.

In order to compare the forecasts with the actual weather, diagrams have been made from the weather numbers for Kew and Scilly, and have been placed below the forecast diagrams for south-east England and for south-west England respectively (Figs. 2 and 3). This method of comparing the forecasts with the weather experienced was used by Dr. W. J. S. Lockyer in a short communication sent a few months ago to the editor of NATURE, who later invited me to prepare the present article. Only the forecasts for one week ahead have been made use of.[2] An examination of these two sets of curves shows that the forecasts, though agreeing with the actual weather at times, yet on the whole show no relationship with the weather experienced. No shifting of the curves backwards or forwards in time makes any approach to a fit between the two except in a few isolated cases. The best fit is probably that for Scilly in August, but even in this case it must be remembered that if the forecasts had been chosen for more than one week ahead the curves would not have been the same as those actually shown. On the whole, there is no such general agreement between the curves of forecast and those of actual weather as would be expected if the forecasts had any sound meteorological basis.

Another way of looking at the results is to take the differences between the forecast numbers and the weather numbers; 0 would mean that the forecast was entirely successful, and 4 that it was as unsuccessful as possible. Taking the forecasts for south-east England for one week ahead and comparing them with the weather numbers for Kew, we find that there were 30 cases with a difference of 0, 72 of 1, 45 of 2, 21 of 3, and 16 of 4. Taking 0 and 1 together we get 102 complete and partial successes as against 82 that were not

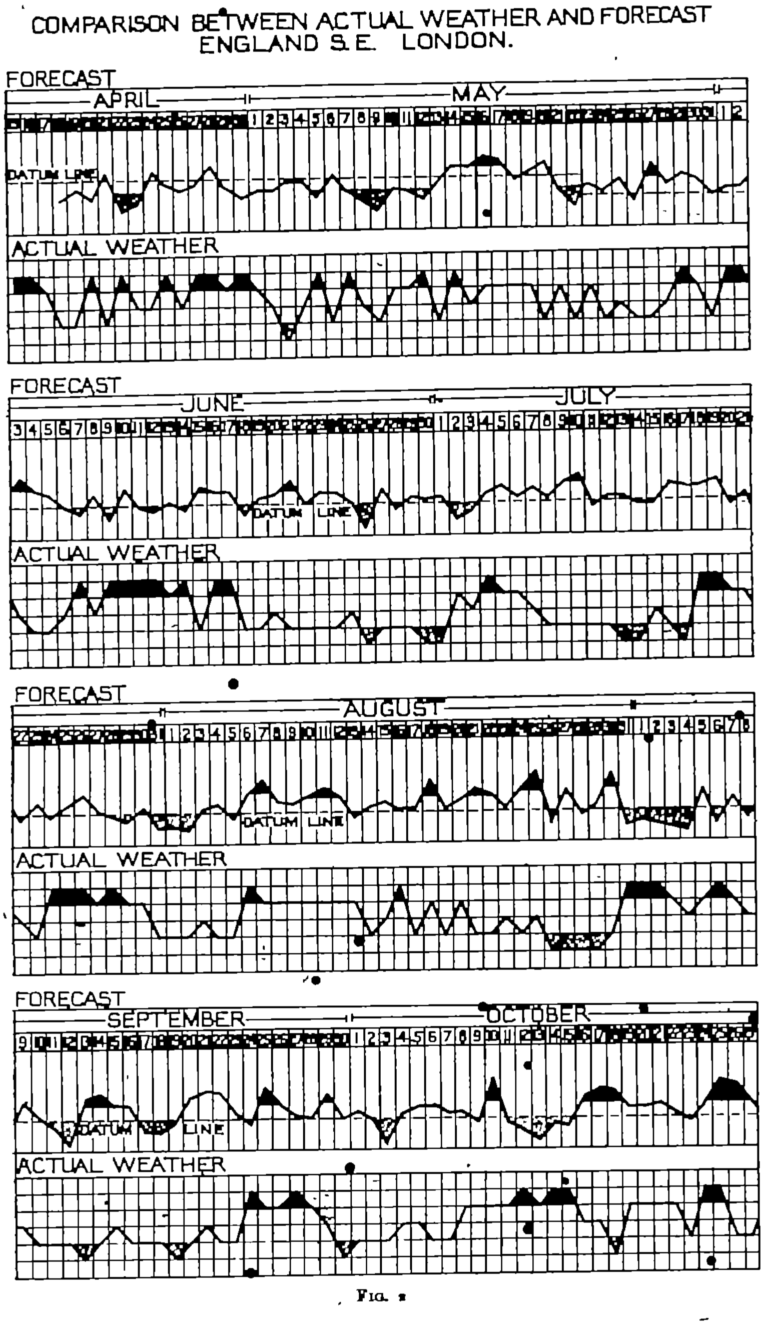

Fig. 2

---

[2] As no charts were issued between April 30 and May 21 the forecasts which should have been for one week ahead for the period May 2 to May 22 were taken from the chart issued on April 30. Similarly, where forecasts for six weeks ahead for the period June 13 to July 3 are under consideration they are taken from the chart issued on May 21.

		One Week. 0	1	2	3	4	Six Weeks. 0	1	2	3	4
Kew.	Actual . .	30	72	45	21	16	30	57	29	28	9
	Chance . .	35	65	44	28	12	31	52	36	26	8
	Ratio . .	0·9	1·1	1·0	0·8	1·3	1·0	1·1	0·8	1·1	1·1
Scilly.	Actual . .	34	67	43	31	9	30	55	34	24	10
	Chance . .	35	62	40	33	14	31	50	33	29	10
	Ratio . .	1·0	1·1	1·1	0·9	0·6	1·0	1·1	1·0	0·8	1·0

a success. This means that the forecasts were successful in 55 per cent. of the cases and failed in 45 per cent. The results for Kew for six weeks, and the results for Scilly both for one week and for six weeks ahead, come out at almost exactly the same percentage. At first sight this seems a definite measure of success for the forecasts, but a further examination of the figures shows that this seeming success is illusory, since the figures are very near to those which would be expected on pure chance. The above table gives the difference between the forecast numbers and the weather numbers for Kew and Scilly both for the forecasts one week and six weeks ahead, together with the numbers which should be expected on pure chance, and with the ratio between them.

From this table it will be seen that the distribution is very close indeed to that of pure chance. If the forecasts had any measure of real success the table should show a high ratio for differences of 0 and 1, and low values for differences of 3 and 4; but there is no indication of this.

To emphasise the fact that the distribution is solely due to chance, the weather numbers have been taken for Kew and have been compared with the forecast numbers for different months, May with October, June with September, July with August, and so on; moreover, the days have been reversed, that is, the first is compared with the last day of the month, the second with the last day but one, and so on; therefore by no possibility can the weather numbers have any connexion with the forecast numbers; the differences come out as follows:—

0	1	2	3	4
35	70	45	27	7

This is in striking agreement with the legitimate comparisons, and emphasises the fact that the latter too have the appearance of being governed by nothing but chance.

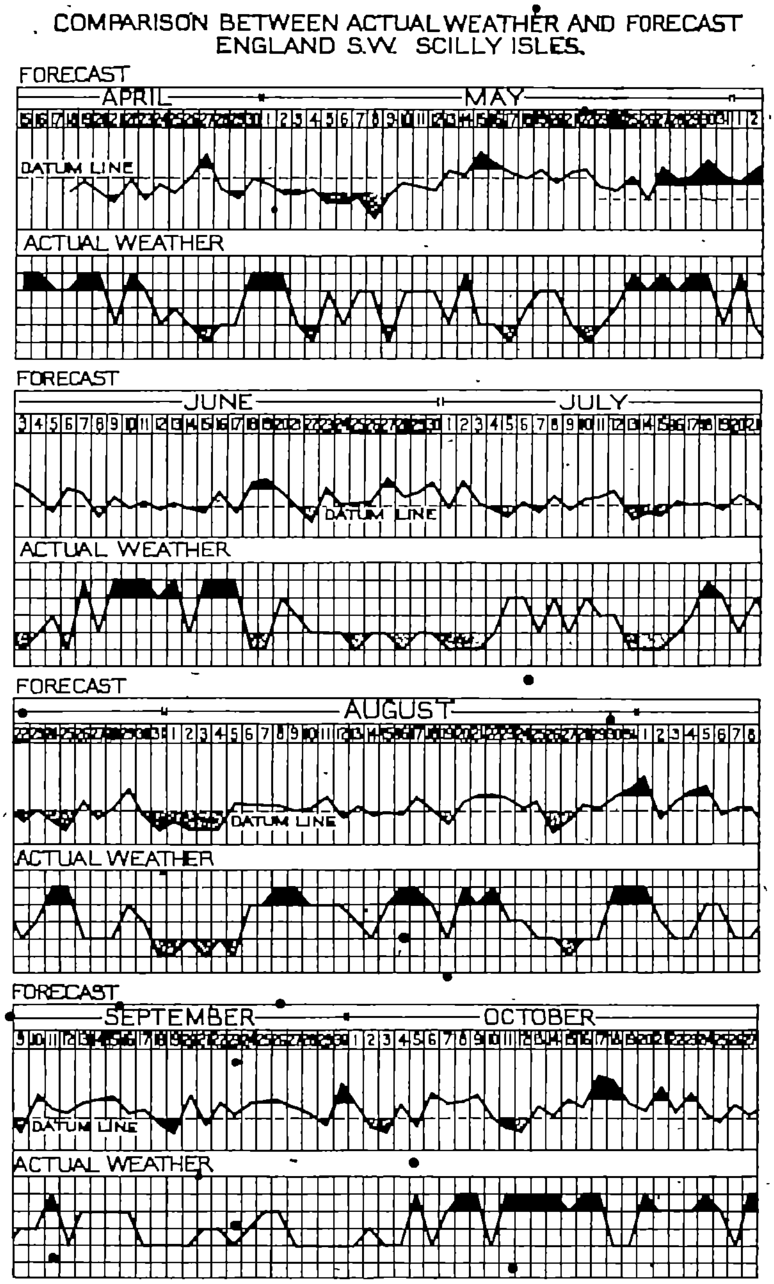

Fig. 3.

Yet another method of examining the figures is to take correlation coefficients between the forecast numbers and the weather numbers. The adjacent table gives these for each month for Kew and Scilly, and for forecasts of one week and six weeks ahead.

	Kew		Scilly.	
	One Week.	Six Weeks	One Week.	Six Weeks.
May . .	0	. .	0	. .
June . .	−0·2	−0·4	−0·3	−0·3
July . .	−0·1	−0·1	+0·1	+0·2
Aug. . .	+0·3	+0·1	+0·6	+0·4
Sept. . .	−0·2	−0·[illegible]	+0·4	+0·2
Oct. . .	−0·3	0	−0·1	−0·1

These coefficients have of course no significance; even the value of +0·6 for August in Scilly, standing alone, does not indicate any real relationship between the two sets of numbers.

It would appear, therefore, from the foregoing considerations that the forecasts, even for one week ahead, have not any success. They are not, in fact, any better than could be obtained by purely fortuitous predictions, and they agree with what one would expect from chance in a very marked way. Nevertheless, it would be interesting to have some account of the methods used. Lord Dunboyne has made a study of meteorology for many years, and if he were to propound a theory of forecasting it would meet with due consideration from meteorologists.

C. J. P. CAVE.

Regions of Compression.[1]

By Dr. J. W. EVANS, F.R.S.

II.

THE accumulation of great masses of sediment destroys for the time being the isostatic balance of the earth's crust, which is restored by the outward flow of the plastic sima beneath them to other areas where the amount of deposits is less, or towards mountains subjected to erosion that diminishes the superincumbent load.

As a result of this outflow the surface on which these thick deposits have accumulated is correspondingly lowered. Such a depression of a previously approximately level floor of deposition may be described as a *sedimentation subsidence*.

Thus thick accumulations tend, by the direct result of their weight, to form and fill hollows in the earth's crust, and so provide for their own preservation. Hence it is that, as the late G. W. Lamplugh pointed out, the areas in which geological formations have now their most important outcrops are those in which they were originally deposited in the greatest thickness.

Where such a sedimentation subsidence has occurred, we must distinguish two constituent parts of the resulting structure: the basal or *external* portion, consisting of the older and more consolidated rocks that formed the original floor of the area of deposition, and the *internal* deposits made up of the sediments and other materials accumulated upon the former.

The depth of the accumulated sediments, and consequently the amount of the subsidence, is greater near the foot of the mountain slopes, and gradually diminishes as the distance from the mountains increased, although at equal distances it will be thicker opposite the outflow of important rivers and less where these were absent.

At a greater distance from the region or regions of erosion, where the amount of sediment deposited was less, the accumulation of calcareous material from the growth of organisms or the precipitation of carbonate of calcium, also derived originally in the main from organic sources, must often have played a similar part in causing subsidence by their weight.

The eruption of lava and ashes will have a like result, intensified by the removal of the material from beneath. The general tendency would, however, be for the load and depression to diminish as the distance from the source increased. At the same time, the inflow of the plastic material from the area of maximum sedimentation would add to the effect of the decrease of the load. Ultimately, at a greater distance, where the deposition was still more reduced, elevation would replace depression.

In the period of comparative quiescence that intervenes between paroxysms of earth movements, resulting in folding and thrusting, the horizontal compressive forces in the earth's crust, which had (for the time being) been exhausted, are once more slowly developing and increasing in strength. At last the crust yields to the pressure where the resistance is weakest. Other things being equal, this will be where the solid crust is bent most deeply down in a sedimentation subsidence. There it is no longer flat and horizontal, and directly opposed to the forces of compression. It has consequently very much diminished powers of resistance, precisely as a pillar bent out of the vertical line is incapable of sustaining the same weight as if it were straight and erect. The weakness of the crust in the subsided area is increased by the fact that the depression of the solid floor through some thousands of feet brings the rocks into regions of higher temperature, and the increase in temperature must be accompanied by a considerable decrease in strength, while the unconsolidated deposits of the interior of the subsidence can add little or nothing to its powers of resistance.

Accordingly, it is in a tract of subsidence that the crust gives way under the forces of compression. It is true that these forces operate on the whole surface of the globe, but immediately the portion with least resisting strength yields, however slightly, the remainder of the great circle on which the yielding takes place is released *pro tanto*, adjusting itself by a movement of elastic expansion, so slow that the resistance opposed to it by the viscosity of the subjacent plastic sima is inappreciable.

It must be remembered, however, that, as already indicated, there are other horizontal forces affecting the earth's crust that may increase or diminish the forces of compression locally, and these may in some instances determine whether the crust yields at one subsided tract or another. When such a yielding has taken place, the probability of the crust giving way at another point is at once greatly diminished, at any rate for the time being.

The first effective action of such compressive forces usually antedates by a considerable period the epoch of maximum disturbance, and is as a rule very gradual and gentle, so that it merely narrows slightly and deepens the area of subsidence. The deposition of great thicknesses of a succession of shallow-water strata is usually explained as due to subsidence by way of isostatic adjustment of the earth's crust, to correct the disturbance of equilibrium from the weight of the sediments accumulated. Prof. A. Morley Davies has, however, directed attention to the fact that there is a limit to such an adjustment, because the density of the sediments laid down is less than that of the plastic subcrustal sima displaced.

Let s be the original depth of the sea, and l the amount by which the sea-bottom is lowered; then $s+l$ will be the thickness of the deposits if they reach the surface of the sea. Let the density of these sediments be ρ_a, that of the plastic sima displaced ρ_b, and that of sea-water ρ_s. Then, if isostatic conditions prevail both before and after the sedimentation, we shall have $\rho_s s+\rho_b l=\rho_a(s+l)$: that is to say, the weight of the sea-water over a unit of area before the deposition of the sediments, *plus* the weight of the sima displaced by the subsidence, is equal to the weight of the sediment deposited. Hence $(\rho_b-\rho_a)l=(\rho_a-\rho_s)s$; so that

---

[1] Continued from p. 17.

$$\frac{l}{s}=\frac{\rho_a-\rho_s}{\rho_b-\rho} \text{ and } \frac{l+s}{s}=\frac{\rho_b-\rho_s}{\rho_b-\rho_a}.$$

Accordingly $l+s$ (the total thickness of the sediments)

$$=\frac{\rho_b-\rho_s}{\rho_b-\rho_a}s. \quad (1)$$

If, however, the subsidence be slowly deepened as the result of gentle lateral pressure, *compression-subsidence*, it is possible for a much greater thickness of deposits to accumulate without rising above sea-level than would be possible according to these calculations, and this appears not infrequently to happen. But it must be remembered that this downward movement imposed on the crust will cause the displacement of still more heavy plastic sima below, and the isostatic balance will be destroyed, because the sediments deposited are less in mass than the material displaced. There should, therefore, be a defect of gravity in areas of deposition affected by gentle lateral pressure. This is, in fact, the case in the Gangetic Plain, as well as in the low tracts lying east and north-east of the Andes.

The strength of the original crust, reinforced by the lateral pressure, may nevertheless be sufficient, for a time, to resist the upward pressure from below. But, if the horizontal forces cease to operate, the downward fold of the crust will ultimately yield to the pressure of the plastic material beneath, and the terrain will rise until isostatic adjustment is restored. It is not improbable that the alternation of marine and continental conditions which is so frequently observed may, in some instances at least, represent changes of this description accompanying intermissions and variations of moderate horizontal compression.

With a continuance, and still more with an increase, of compression, the exterior framework of the subsidence will gradually close, and throw the interior sediments, still soft and plastic, into folds of ever-increasing complexity. As these develop, the interior accumulations will tend to rise instead of sinking, and to pile themselves up into mountain masses concentrated on a limited portion of the earth's crust, which will be once more loaded in excess of the isostatic balance. A new subsidence—a *folding subsidence*—will ensue, with greatly increased displacement of the sima.

When the isostatic balance is once more restored, the summit of the mountain folds will still rise high above the adjoining plains; but a much greater portion will lie far below, and the protection of most of the sediments of the internal structure from future destruction will be still further assured.

Let, as before, ρ_a be the density of the sial and ρ_b that of the sima, and let j be the depth below the sea of the base of the mountain folds, consisting mainly of sediments, including for the present purpose both the rocks of the original surface of deposition and the later, interior, sediments; and let h be the height of the mountains above the sea, m the height of the plains, and c the thickness of the sial of which they are formed.

Then, in order to preserve isostatic balance, we must have

$$\rho_a c+\rho_b(j+m-c)=\rho_a(h+j). \quad (2a)$$

So $$\rho_b(j+m)-\rho_a(h+j)=(\rho_b-\rho_a)c. \quad (2b)$$

and $$c=\frac{\rho_b(j+m)-\rho_a(h+j)}{\rho_b-\rho_a}=j-\frac{\rho_a h-\rho_b m}{\rho_b-\rho_a}. \quad (2c)$$

The upper portion of the folds will commence to be eroded as soon as they rise above the surface, and will never reach the height which is obtained by continuing and completing the portion of the folding that can now be observed. Consequently, the base of the folds is not now and never has been so deep as would have been the case, but for the progress of erosion and consequent removal of load.

The gravitation data obtained by the Coast and Geodetic Survey of the United States in North America are best interpreted as indicating that the maximum depth of the folds is about 86 km. below sea-level. The average height of the crests may be taken as about 3500 m. above sea-level. We thus know roughly both j and h, but the value of c, the thickness of the sial of the plains, remains to be determined.

This amount is also concerned in the isostatic balance between the continental plains and the sea-bed. Let the depth of the sea outside the continental shelf be S, and the height of the plains above the sea be, as before, m. Then the mass of the sial below the plains must be in isostatic balance with the sea-water and the sima below it, down to the level of the base of the sial of the plains.

Hence

$$\rho_a c=\rho_s S+\rho_b(c-m-S) \quad (3a)$$

when ρ_s is, as before, the density of the sea-water.

So $$(\rho_b-\rho_s)S+\rho_b m=(\rho_b-\rho_a)c \quad (3b)$$

and $$c=\frac{(\rho_b-\rho_s)S+\rho_b m}{\rho_b-\rho_a}. \quad (3c)$$

But since $\rho_b(j+m)-\rho_a(h+j)$ also $=(\rho_b-\rho_a)c$, $\quad (2b)$

we have $$\rho_b(j+m)-\rho_a(h+j)=(\rho_b-\rho_s)S+\rho_b m. \quad (4a)$$

Hence $$\rho_b(j-S)=\rho_a(h+j)-\rho_s S \quad (4b)$$

and $$\rho_b=\frac{\rho_a(h+j)}{j-S}-\frac{\rho_s S}{j-S}. \quad (4c)$$

If h is taken as 3·5 km., j as 86 km., S as 4·7 km., and ρ_s as 1·03,

$$\rho_b=1{\cdot}10086\rho_a-0{\cdot}059545.$$

In view of the uncertainty of the data, these figures can only be regarded as a provisional approximation; but they are sufficient to indicate the general nature of the relation between ρ_b and ρ_a. The probable values of ρ_b for different values of ρ_a are shown in the first and second columns of the accompanying table.

With any corresponding values of ρ_a and ρ_b we can determine the value of c from either of the equations (2c) or (3c). These values are set out in the fourth column of the same table.

ρ_a. Assumed density of the sial	ρ_b. Corresponding density of the sima.	$\rho_b - \rho_a$. Difference.	s. Thickness in kilometres of the sial of the plains.
2·35	2·5275	0·1775	41·1
2·40	2·5825	·1825	41·4
2·45	2·6376	·1876	41·7
2·50	2·6926	·1926	42·0
2·55	2·7476	·1976	42·2
2·60	2·8027	·2027	42·5
2·65	2·8577	·2077	42·7
2·70	2·9128	·2128	43·0

It is remarkable how little the calculated thickness of the sial of the plains varies with the different values of the density of the sial and sima. It is considerably greater than the 15 km. deduced by Dr. H. Jeffreys from seismic considerations or the value assigned to it by H. Washington, 15 km. to 20 km., or, indeed, than I should myself have thought probable, but much less than the figures arrived at by Wegener. Although the data are only known approximately, it is difficult to see how the thickness can differ very considerably from 40 km., unless the depth, j, of the mountain folds is much greater and the difference $\rho_b - \rho_a$ less. For provisional purposes a density of 2·60 for the sial and 2·80 for the sima may be assumed. Such a density for the sima would imply that it is partly crystallised.

While the interior sediments of a subsided area are thrown into complex folds which sink ever deeper below the surface, the exterior rocks that formed the surface of deposition are forced down into hollows, which constitute folds simpler than those of the interior sediments and distinct from them. In the course of these movements they are stretched, and ultimately torn apart into lenticles. In addition, as a result of lateral compression and of isostatic adjustment, they may be and usually are fractured in thrusts and slip-faults. When the interior rocks have become compacted like those of the exterior, they too are forced to accommodate themselves by similar faulting to the forces acting upon them. Thrust-faults will predominate, and result in still further local accumulation in the subsided area and still further subsidence, a *thrusting subsidence*.

The approximate coincidence in the Boulonnais of the post-Jurassic infra-Cretaceous movements, as well as those of later date with the Hercynian folding, induced a number of observers, such as Godwin-Austen, Marcel Bertrand, and Charles Barrois, to formulate a law that movements tend to repeat themselves along the same tracts. That there is some truth in this principle cannot be denied. Unless folded rocks have been thoroughly consolidated and welded together, a renewal of the folding on the same lines will be comparatively easy, and in the case of faults it is a familiar fact that successive movements frequently take place along the same fault-plane. At the same time, T. O. Bosworth, in describing the relation of the Trias to the pre-Cambrian rocks of Leicestershire, has shown that the settlement of later rocks overlying an ancient ridge will cause deformation in the stratification more or less parallel to the contours of the surface of the older rocks. Probably still more important is the fact that the accumulation of the sediments at the foot of a mountain range will, on the principles already explained, tend to produce another system of folding parallel to the first. But this result will be controlled to a considerable extent by local conditions and more especially by the thickness of sial beneath; for it is probable that a sedimentation-subsidence forms more easily where the depth of the sial is less, as even at moderate depths and temperatures the sima is more yielding than the sial in the absence of volatile constituents. However, as Prof. Pruvost has shown, the correspondence is by no means so close, even in the Boulonnais, as to amount to identity of direction.

O. Barré, A. Bigot, and Paul Lemoine suggest the existence of a supplementary inverse principle, according to which an anticline succeeds to a previous syncline, and vice versa. This Lemoine illustrates by the buried ridge beneath the Thames Valley syncline and the supposed syncline beneath the Wealden anticline. But in the former case the synclinal axis is only approximately parallel to the ridge below it; and there is no reason to believe that the Palæozoic floor rises up on the south side of the Weald. It is far more likely that its descent on the northern side is in the nature of a monocline.

The tracts of folding and mountain building that I have discussed belong to great systems in different parts of the world with a direction approximating to the parallels of latitude, and would seem to owe their orientation to the meridional forces, which may themselves be attributed to variations in the angular velocity of the earth's rotation. I have no time to refer to the folds associated with the great ring of compression that encircled the Pacific in Mesozoic and early Kainozoic times. The position of this compression would appear to be determined by a general drift of continental masses towards the centre of that ocean, caused, I have suggested, by a maximum of gravitation beneath it.

To these two great systems of folding, their intersections and interference, may be referred nearly all the orographical features of the globe, which have come into being since the close of the Caledonian activity in early Devonian times; while the mountain ranges that belong to neither category not improbably owe their position and orientation to the existence of pre-existing ranges which have determined the development of new regions of folding in the manner already indicated. We know too little of the distribution and orientation of the continental masses and their relation to the position of the equator and the poles and to the variations of gravitation in older Palæozoic and still earlier times to enable us to say how far the directions of earlier folding are consistent with these suggestions.

I make no pretension to enunciate a new theory of mountain building. It has been my endeavour to tell a connected and consistent story of the steps by which mountain folds have come into existence and developed; how they owe their origin in general to great accumulations of sediments, the product of the denudation of the mountains raised in a previous period of folding; how a tract of subsidence resulting from sedimentation and filled by sediment becomes a tract of weakness in the earth's crust; how the time arrives when under the slowly increasing horizontal compression the subsided area yields and closes, so that the contained sediments are forced up in folds to form a new mountain range, while the earth's crust is left for the time being in a state of relaxation, at the mercy of minor forces which in the time of its strength it had no difficulty in resisting; how it is gradually consolidated once more by the reviving forces of compression, while new regions of weakness are being prepared by new accumulations of sediment, and another cycle of mountain building begins.

Obituary.

Sir William Augustus Tilden, F.R.S.

By the death of Sir William Tilden on Saturday, Dec. 11, in his eighty-fifth year, British chemistry lost one of its best known and most loved representatives. Born before Frankland had endowed the atom with valency, or Cannizzaro had used the implications of Avogadro's hypothesis to fix its relative weight, his span of life bridged the gulf between conceptions so widely separated as the indivisible unit of that remote time and the *congeries* of protons and electrons of the present day.

As a boy, Tilden was sent to various private schools and finished that part of his education at Bedford Modern School, where, during the two years of his stay, he helped to found the school scientific society, which bears his name. So far as can be ascertained, his interest in chemistry was first aroused by the experiments which a visiting tutor at the last of these private schools carried out in class to illustrate his teaching. Being given the choice of a career, Tilden in 1857, on leaving school, chose that of chemist. But through a confusion of ideas on the part of his guardian, more pardonable then than now, he started as the apprentice of a pharmacist, the late Alfred Allchin of Barnsbury in North London, who had been Redwood's assistant in the Pharmaceutical Society's School in Bloomsbury Square. He was therefore of the company of Scheele, Dumas, and others, who found their way to eminence in chemistry through the discipline and experience of the old type of pharmacy.

While attending classes at Bloomsbury Square during his apprenticeship, Tilden was attracted to Hofmann's lectures at the Royal College of Chemistry in Oxford Street, which opened up to him a new world and exercised a profound influence on his career. In 1862 he became assistant to Dr. John Stenhouse, F.R.S., but a year later returned to the School of Pharmacy, this time as demonstrator in chemistry under Attfield—a position he occupied until 1872, when, abandoning pharmacy for chemistry, he became science master at Clifton College under Percival, afterwards Bishop of Hereford. It may not be without interest to note that one of his students at Bloomsbury Square, the late W. A. Shenstone, F.R.S., who like himself had been a Jacob Bell Memorial scholar, succeeded him at Clifton.

From Clifton, Tilden went to Birmingham in 1880 as professor of chemistry and metallurgy in the newly founded Mason College and took an active share in the development of that institution; but in 1894, three years before it achieved university status, he was called to the chair of chemistry in the Royal College of Science, South Kensington, in succession to the late Sir Edward Thorpe. On his retirement from South Kensington in 1909—he had succeeded the late Prof. J. W. Judd, F.R.S., as Dean of the College in 1905—he received a knighthood and was given the title of emeritus professor in the Imperial College of Science and Technology. Thereafter, he occupied himself with literary work—chiefly studies in historical chemistry—and, for recreation, with his garden, of which he was justly proud. Among the more important of his books may be mentioned "Short History of the Progress of Scientific Discovery," published in 1899; "The Elements" (1910); "Chemical Discovery and Invention in the Twentieth Century" (1917); "Famous Chemists: the Men and their Work" (1920).

In the field of original research Tilden was first busied with subjects of pharmaceutical interest, out of one of which, the study of dilute nitro-hydrochloric acid, a method was developed in 1874 for the production of nitrosyl chloride in quantity, a reagent used largely by him in the investigation of the terpenes. Pinene nitrosochloride, the first of the additive compounds formed by its aid, was isolated by him in 1875, and others followed; but his work on these unsaturated hydrocarbons, and the conclusions reached about their constitution, are less likely to be remembered than his discovery of the polymerisation of isoprene into caoutchouc, which supplied the first clue to the manufacture of indiarubber by synthetical means. Among the other subjects which claimed his attention, mention may be made of his work on the relation of specific heat to atomic weight which formed the subject of the Bakerian lecture before the Royal Society in 1900. By awarding him the Davy medal in 1908, that Society set its seal on the merit of his contributions to knowledge.

Recognition also came to Tilden from universities and scientific societies. He received the honorary degrees of Sc.D. (Dublin), D.Sc. (Victoria), and LL.D. (Birmingham); became a fellow of the Royal Society in 1880; was a fellow of the University of London; corresponding member of the Russian Imperial Academy of Sciences; and honorary member of the Pharmaceutical Society; president of Section B (Chemistry) at the Bath meeting of the British Association in 1888; president of the Institute of Chemistry in 1891–94; treasurer of the Chemical Society in 1899–1903, and its president in 1903–5. His British Association address was noteworthy as an expression of his views on the teaching of chemistry; his tenure of the chair of the Institute of Chemistry for the adoption of the figure of Williamson's statue of Priestley in Birmingham for the seal of that body; and his presidency of the Chemical Society for the initiation of the invaluable series of "Annual Reports on the Progress of Chemistry," and of the movement for the admission of women to the fellowship, which, to his regret, was not endorsed by the Society until after the War.

Always sure of a welcome at any meeting he might attend, and listened to with pleasure when he intervened in discussions or debates, Tilden maintained his interest in chemistry and chemists to the end. Even when infirmity, which might have deterred many a younger man from making the effort, came upon him, he would travel from Northwood to attend meetings of the Chemical Society's council. These visits became less frequent as his sight began to fail, and after the summer of 1923 he was seen only once more at Burlington House, when, at the annual general meeting in 1924, as those who heard him will never forget, he made his last speech, rich in reminiscences of his early days as a fellow of the Society. To those who had the privilege of serving on his staff in Birmingham or London, he was ever the stimulating counsellor and appreciative chief. Nor were his students slow to recognise that in him they had a teacher who never spared himself in their interest, and, giving them of his best, he received in return that consideration which old-world courtesy invariably calls forth.

Sir William Tilden was twice married: first in 1869 to Charlotte, daughter of the late Robert Bush, and secondly, in 1907, to Julia Mary, daughter of the late C. W. Ramie. He is survived by Lady Tilden and by a son of the first marriage, Philip Armstrong Tilden, who has achieved distinction as an architect. The funeral at Northwood Parish Church on Wednesday, Dec. 15, was attended by a large body of mourners, including besides relatives the representatives of societies connected with chemistry, pure and applied, and many personal friends.

W. P. WYNNE.

SIR JAMES WILSON, K.C.S.I.

WE regret to record the death of Sir James Wilson, late of the Indian Civil Service, on Dec. 22 at his residence, Annieslea, Crieff. He was a recognised authority on a variety of topics connected with India —administrative, economic, philological, and ethnographic. After his retirement from the Indian service in 1911, when he settled in London, being keenly interested in agricultural matters, he acted as superintending inspector under the Board of Agriculture and Fisheries, and became a governor of the Agricultural Organisation Society; in 1914 he was appointed permanent delegate for Great Britain, Canada, Australia, New Zealand, and South Africa, to the Institute of Agriculture in Rome.

Sir James Wilson was born on Feb. 27, 1853, the son of the Rev. John Wilson, of Dunning, Perthshire. He was educated at Perth Academy and, after passing the Indian Civil Service examination in 1873, graduated at Edinburgh and then proceeded to Balliol College, Oxford, where he obtained the Boden Sanskrit scholarship, but did not stay long enough to take a degree. He went to India in 1875, and was posted to the Punjab. A distinguished administrative career, which included such high official appointments as secretary to the Punjab Government and the Financial Commissioner, membership of the Punjab Legislature, and, on Lord Curzon's selection, secretary to the Government of India in the Revenue and Agricultural Department, and finally Financial Commissioner of the Punjab, was recognised by the award of the C.S.I. in 1900 and the K.C.S.I. in 1909, two years before his retirement.

Apart from his official duties, Sir James Wilson's interest lay especially in investigating the dialects and folklore of his province. He wrote on tribal customs in the Gurgaon, Sisra, and Shahpur, compiled a gazetteer of the latter district, and wrote a grammar of Western Punjabi. Similar interests in folklore and dialect after his retirement produced "Lowland Scotch as Spoken in the Lower Strathearn District of Perthshire," published in 1915, "The Dialects of Robert Burns," and recently, "Scottish Poems of Robert Burns in his Native Dialect." He had also completed a book on the dialects of central Scotland.

WE regret to announce the following deaths:

Dr. Laurence Pullar, who, by a gift of £10,000, made possible the survey of the Scottish lochs carried out by the late Sir John Murray, and later, with Sir John, edited the six large volumes containing the results, on Dec. 22, aged eighty-eight years.

Dr. H. Campbell Ross, Director of the McFadden Research Foundation at the Lister Institute of Preventive Medicine, London, on Dec. 14, aged fifty-one years.

Mr. T. S. P. Strangeways, Huddersfield lecturer in special pathology and Director of the Research Hospital at Cambridge, on Dec. 23, aged sixty years.

News and Views.

THE New Year honours list includes the names of the following men of science and others associated with scientific work :—*Privy Councillor* : The Hon. W. G. A. Ormsby-Gore, Under-Secretary of State for the Colonies and president of Section E (Geography) of the British Association at the Oxford meeting in 1926. *Knights* : Dr. Henry Head, who has made distinguished contributions to our knowledge of the nervous system; Mr. A. E. Kitson, Director of the Geological Survey, Gold Coast Colony; Mr. J. C. W. Reith, Managing Director of the British Broadcasting Company; Dr. D. Milne Watson, Governor of the Gas Light and Coke Company, London. *K.C.B.* (*Civil Division*) : Dr. G. Macdonald, Secretary to the Scottish Education Department. *C.B.* (*Civil Division*) : Mr. H. T. Tizard, Principal Assistant Secretary, Department of Scientific and Industrial Research. *C.I.E.* : Lieut.-Colonel J. W. Cornwall, lately Director, Southern India Pasteur Institute, Coonoor, India; Mr. D. Anstead, Director of Agriculture, Madras; Mr. D. Milne, Director of Agriculture, Punjab. *K.C.M.G.* : Prof. W. Mitchell, Vice-Chancellor of the University of Adelaide, in recognition of his services to the Commonwealth of Australia. *C.B.E.* (*Civil Division*) : Mrs. Eugénie Strong, Assistant Director of the British School of Archæology in Rome.

LORD BALFOUR, on behalf of the Prime Minister, will receive a deputation on Feb. 15 from the British Waterworks Association, the Salmon and Trout Association, the Society of Medical Officers of Health, and other bodies, who wish to persuade the Government to set up a central authority to deal with the vexed question of river pollution in Great Britain. In our leading article of Jan. 1 we pointed out the necessity for scientific research in order to deal with many of the problems which present themselves, and outlined the preliminary investigations which have been carried out by the Select Committee on River Pollution during the last five years. The deputation will press for an extension of the relatively small amount of research already in progress, particularly in regard to the best methods of dealing with various harmful trade effluents. It would clearly be an advantage for the scientific investigations carried out by the State and dealing with water supply, sewage disposal, and river pollution, to be under one authority, since they are to a large extent interdependent. The movement towards keeping rivers free from pollution by industrial wastes is in no sense hostile to the industries causing the damage, the bodies concerned believing that the remedy is to be found in centralisation of effort and the application of scientific method to the many problems which have hitherto found no solution. The honorary secretary of the joint committee promoting the deputation is Mr. C. N. Hooper, Fishmongers' Hall, London Bridge.

THE opening of a public telephone service between London and New York this month proves that great progress has been made during the last two years by the radio engineers engaged on long-distance telephony. The charge is to be at the rate of £15 for three minutes' conversation and £5 for every additional minute. If other callers are waiting the speaker is limited to twelve minutes. If connexion be made with the number required but neither the person called nor a substitute accepted by the caller answers, a report charge of £2 only will be made. The problems that the engineers had to overcome mainly arose from the overloading of the ether with radio waves. The wave band chosen lies between 5000 and 6000 metres, and there are forty radio-telegraphic companies already taking up nearly all the available wave-lengths in this band. Very delicate switching devices controlled by the voice are used. When the London subscriber speaks, the circuit to New York is automatically switched on, and the circuit from New York to London is switched off. As soon as he ceases speaking the switches assume their normal position. When the New York subscriber replies, the converse operation takes place.

THE Post Office gave a very successful demonstra-of trans-Atlantic radio-telephony to the Press on Mar. 7 of last year, when for four hours conversation took place between English press representatives and their confrères in New York (see NATURE, Mar. 13, 1926, p. 387). The difficulties connected with atmospherics have not yet been completely overcome. The phenomenon of 'fading' occurs shortly after the time of sunset each day. It varies therefore with the season, occurring between 5 P.M. and 7 P.M. in winter, and between 8 P.M. and 10 P.M. in summer. When the time is 2 P.M. in Great Britain it is about 9 A.M. in New York. Hence between 2 P.M. and 6 P.M. the business times overlap. After this time, if the New York subscriber calls up, he will be put through to the London subscriber at his private residence. In the initial stages, however, it is not proposed to have a continuous twenty-four-hour service. The starting rates have been fixed on a commercial basis, and will be reviewed from time to time as experience is gained in working the service.

IN July last, Dr. W. J. S. Lockyer, director of the Norman Lockyer Observatory, Sidmouth, sent us a note giving the results of a comparison of the 50-day weather forecast for April-June prepared by Lord Dunboyne for the *Daily Mail*, with actual weather experienced. Sidmouth is in such a geographical position that the predictions for the division of Great Britain marked "England, S.W., Scilly Isles" on Lord Dunboyne's chart could be fairly applied to it. Dr. Lockyer therefore constructed a similar chart showing, on the same scale and for the same period, the weather forecast compared with fact. There was little resemblance between the two curves, but it seemed to us that the subject merited inquiry in more detail than Dr. Lockyer had been able to give to it. We therefore invited Capt. C. J. P. Cave to make such an examination over a longer period, and we were fortunate in obtaining his consent to do so. The results are described in an article which appears elsewhere in this issue, and the general conclusion reached is that the success or otherwise of the predictions is mainly a matter of chance. We sent Lord Dunboyne a copy of the article and offered him space for any comments he might care to make in reply to it. Lord Dunboyne, however, regretted that he had not the time to prepare such a reply, but his brother, Capt. the Hon. Robert Butler, has consented to do so, and we propose to publish his communication in an early issue.

EARLY on Jan. 1, a series of violent earthquakes disturbed the southern part of the Imperial Valley, which occupies the south-eastern corner of California and the northern part of Lower California, Mexico. Many buildings were destroyed in the border towns of Calexico and Mexicali, and water-mains were broken. It is estimated that about fifty shocks were felt during the first ten hours. The epicentre coincides very nearly, if not exactly, with that of the earthquakes of June 22, 1915, studied by Mr. Carl H. Beal (*Amer. Seis. Soc. Bull.*, vol. 5, 1915, pp. 130-149). On this day there were two violent shocks, both of intensity 9 (Rossi-Forel scale). The area disturbed by them was about 50,000 square miles, but the value of the property destroyed was only about one-third of that lost on Jan. 1. The Imperial Valley is almost entirely below sea-level and lies in a depression which, in recent geological times, was a branch of the Gulf of California. The district is traversed by some remarkable faults with a general north-west and south-east direction. One of these, the San Jacinto fault, apparently branches from the San Andreas rift, with which the Californian earthquake of 1906 was connected. It has been traced close up to the epicentral area of the earthquakes of 1915 and 1927, and is believed to traverse the Imperial Valley. Mr. Beal suggests that the earthquake of 1915 may have been caused by a displacement along this important fault.

Some results of importance obtained from a careful examination of the prehistoric monuments of the island of Minorca, which extended over a period of some months, are described by Mr. Frederick Chamberlin in the *Times* of Dec. 30. It has generally been held that the *talayots* of Minorca, great mounds of huge, rough uncemented stones 26 ft.-30 ft. high, were comparable with the better known *nurhags* of Sardinia. This comparison was based on the view that the *talayot* in some, if not all, cases was built hollow with an entrance, resembling in this respect a chambered cairn. Mr. Chamberlin examined 186 *talayots*, some previously unknown. Of these, 107 were in a sufficiently good state of preservation to permit him to say that 32 only, or one out of three, had ever had an entrance of any sort, while three alone had an interior chamber, and only one more than one apartment. It is clear, therefore, that the *talayot* is not comparable to the *nurhag* and, indeed, is a monument without a parallel. Associated with the *talayot*, and usually within a hundred feet of it, is a class of monument known locally as a *taula*—a two-stoned monument 5 ft.-12 ft. high in the shape of a Greek T, the flat top stone being fully 12 ft. long. Ten of these are now known. Each is surrounded by a horse-shoe-shaped wall pierced by a doorway surmounted by a single-stone lintel. The two classes of monument clearly stand in relation one to another, though there does not appear to be any evidence of orientation. Sir Wallis Budge has expressed the opinion that the *talayots* are pyramids of a funereal nature, and the *taulas* altars for sacrifice or other funereal ceremonies. A third class of monument, called *naus* from its resemblance to a ship, of which sixteen are known, has an elliptical chamber 15 ft. long by 7 ft. high, and appears to have served as a tomb for dwellers in the numerous caves in the neighbourhood.

The first five parts, constituting the first volume of the "Nomenclator animalium, generum et subgenerum," have now been issued by the Prussian Academy of Sciences. Each part consists of 160 pages, 12¼ × 9½ inches, printed in three columns with about 50 names to the page. The work will be completed in four more volumes and will contain more than 200,000 entries. It is hoped that the last part will be issued at the close of 1929. The promoters of this great work seem to have found some difficulty in making it known, and it has therefore been decided to extend to March 31, 1927, the term during which the names of subscribers will be received. The subscription price is 15 marks for each part, or 75 marks per volume. After that date the selling price will be raised to 20 marks a part. Payments should be made by cheque or money order to the Preussische Akademie der Wissenschaften, Berlin, N.W.7, Unter den Linden 38. The Academy also offers the "List of Literature" used in the "Nomenclature," for 10 marks; it occupies 288 pages. During the progress of this laborious undertaking, two successive editors, F. E. Schulze and W. Kükenthal, have died. The present editor-in-chief is Prof. K. Heider, and the secretary is Prof. Th. Kuhlgatz. Our readers may fittingly be reminded that the British Association, the Linnean Society of London, and a few individuals in Great Britain have helped the work by donations amounting to about £500.

It should scarcely be necessary for us to emphasise the extraordinary service that this publication renders to every working zoologist. It cannot, indeed, supersede Sherborn's "Index Animalium" in course of publication by the Trustees of the British Museum, a work which the German editors say "kann nicht genug bewundert werden." But the vaster scope of Sherborn's "Index," and the more exhaustive method by which it is compiled, indicate that no man living can expect to see its completion beyond 1850. The Prussian Academy, adopting a more rapid method, gives us a list of generic and subgeneric names down to 1922, those for the last twelve years being copied, without further reference, from the indexes to the "Zoological Record." The names of fossil animals are of course included, and almost excessive care has been taken to reproduce every variation in spelling down to obvious and ridiculous misprints. We have checked some of the earlier parts by other indexes accessible to us and have found an occasional date or page-number wrong (*e.g.* 1646 for 1846, 11 for 116), some initials incorrect, and the † indicating 'extinct' wrongly omitted or inserted. Such almost inevitable slips or misprints scarcely affect the usefulness of the work. Actual omissions are exceedingly rare, and if some unwarranted names have found their way in, they will do no great harm. Every serious student will continue, as heretofore, to verify his references. The great thing is to find the reference, and that is labour worth paying for.

According to a report of the Nairobi correspondent of the *Times* which appeared in the issue of Dec. 28, Mr. L. S. Leakey, of the Cutler Dinosaur Expedition, has discovered a complete human skeleton at Nakuru buried at a depth of twelve feet in the flexed position with knees drawn up to the chin. With the skeleton were more than a hundred stone implements described as 'Mesolithic,' mostly lunates and backed points of obsidian with a few bone points. The skeleton is that of a 6 ft. man and is said to be "not negroid." The skull has a nose of medium width and is not prognathous. Mr. Leakey is stated to regard this man as belonging to the "Wayland Magnosian" period of Uganda. Judging from the description, the implements would appear to belong to a type already found in this area which Mr. Wayland himself regards as comparable to Azilian. Mr. Leakey's work in investigating stone age remains in Uganda is being financed in part by the Percy Sladen Memorial Fund; but it is hoped that the interest which has been aroused by this discovery may call forth further financial assistance and also that the Kenya Government will agree to assist to a limited extent in 1927. Should the report be fully substantiated in all its details, the discovery is likely to prove of considerable importance in African archæology.

THE council of the *Field* Distemper Research Fund states that the investigations so far pursued have confirmed the view that canine distemper is caused by a filter-passing ultra-microscopic virus, and the symptoms of the disease itself have been disentangled from those of the many secondary infections that occur. Several puppies have been rendered so far immune by inoculation that infection afterwards with the virus produces only a slight and transitory effect. The material employed for the inoculation is at present of a crude nature and of uncertain and inconstant strength, so that the procedure has not yet reached the stage when it can be widely used, but progress in this direction is anticipated. The work is being carried out at Mill Hill in collaboration with the Medical Research Council; and the Duke of Portland, president of the Distemper Research Council, appeals for further donations to the fund, which should be forwarded to the organising secretary, Windsor House, Bream's Buildings, London, E.C.4.

WE have received the second annual report of the Board of Management of the London School of Hygiene and Tropical Medicine to the Court of Governors. The report, which is signed by Sir Alfred Mond, chairman of the Board, gives a brief account of the activities of the school and the progress made during the year. In the Tropical Division, Dr. Balfour reports that the extended courses of study have not led to any decrease in the number of students; in fact, the average number attending is slightly higher than last year. Since the Seamen's Hospital Society has signified its intention of maintaining the hospital at Endsleigh Gardens for a limited period only, the Minister of Health, upon representations made by the Board of Management, has appointed a committee to consider how the necessary clinical and pathological facilities for the study of tropical diseases can best be secured to the School. In order to increase the research work of the School, the Board has decided to apply the capital as well as the income of the Milner Research Fund to this purpose; as part of this plan, Dr. A. W. Grace has been nominated to proceed to the West Indies to undertake research on filariasis, and a contribution of £500 per annum for two but not more than five years has been made towards his expenses; the larger part of the cost of this expedition is being borne by the Royal Society. It is hoped that the formal opening of the Field Station of the Institute of Agricultural Parasitology, at Winches Farm, will soon take place; the work is under the intermediate direction of Prof. R. T. Leiper.

IT is satisfactory to learn from the report that the deficit taken over with the London School of Tropical Medicine has been wiped out, owing to an extra grant from the University Grants Committee and a donation from the executors of the late Mr. Alfred de Rothschild; but it is feared that the work of the Tropical Division cannot be carried on without loss, unless increased financial aid is forthcoming. Steps are being taken to enlarge the library, which at present is related entirely to the Tropical Division, so as to build up a library of hygiene, in advance of the opening of the new School. Unfortunately, the progress of the building has been seriously delayed by the coal strike, since the building committee, after careful consideration, felt they would not be justified in departing from their stipulation that only British steel should be used. However,, the steel work should be completed within twenty-five weeks of the termination of the coal dispute, that is, approximately by the middle of this year. Meanwhile, steps have been taken to make appointments to the chairs of bacteriology and immunology, and of epidemiology and vital statistics; thus the Board has the advice and assistance of the two professors, Prof. W. W. C. Topley and Prof. Major Greenwood respectively, in settling the details of the accommodation in the new school and its equipment. During the year Prof. McDowall, of King's College, has given courses of lectures in physiology as applied to hygiene. We welcome the report as evidence of the increasing part the School will play in university life in London.

DR. C. S. MYERS gives a very interesting and lucid account of vocational guidance and selection in the *Nineteenth Century* for November last. By vocational guidance is meant the expert advice offered to a person in regard to his choice of employment; by vocational selection is meant the discovery of the best worker for a given job. Dr. Myers discusses the effects of having 'the round peg in the square hole,' and rightly attributes much industrial discontent, unhappiness, inefficiency, and high labour turn-over to the presence of people in jobs for which they are intellectually and temperamentally unfitted. A high labour turn-over in jobs where security of tenure does not prevail is indicative quite frequently of bad selection. The only satisfactory reason for taking up a particular job is that one has the ability to do it and also that one prefers it to any other: such is, of course, a counsel of perfection, but it is impossible to overestimate the evil effects of forcing a child for reasons extraneous to the work itself or to the child into situations for which he is not adapted. The author points out that children are not, as a rule, the best judges of their capabilities or even interests, being frequently influenced by fashion, prestige, or fleeting interests. Teachers often do excellent work, but not all are either sufficiently gifted or trained for the necessary diagnosis.

OF recent year, special study has been devoted to the problems of guidance and selection, and it is now possible by the application of psychological tests to assess a child's abilities and advise accordingly. Dr. Myers wisely insists in his article that a mere mechanical application of tests is useless: they are of diagnostic value, but must always remain the servant, not the master, of the vocational adviser. Everybody who has come in contact with industry in its different fields has been impressed by the dissatisfaction of many who have had to enter an uncongenial trade or profession and are now too old to change. One point relevant to this discussion might be stressed, namely, that society as well as the individual parent must cease to look upon certain occupations as more respectable than others. How many miserable clerks would be happy as manual workers were it not that some grades of society consider clerical work more respectable than manual work?

THE Illumination Research Committee of the Department of Scientific and Industrial Research has issued Technical Papers Nos. 1, 2, and 3. dealing respectively with the terminology of illumination and vision, the transmission of window glasses and the effect of the enamelled steel reflectors used in works. The measurements on which the last two reports depend were made at the National Physical Laboratory by members of the staff. Of the importance and value of the two to industry there can be no doubt and they should command a ready sale. In a prefatory note to the first report the chairman of the Committee explains that as the technical terms used in illumination are not widely known, it has been thought desirable to publish explanatory notes so that readers of future reports would have full knowledge of the terms used in them. The prices of the three reports—9*d.*, 6*d.*, and 1*s.* respectively, seem high compared with the prices of corresponding publications of the United States Bureau of Standards or of those issued by the Support of Workings in Mines Committee of the British Mines Department, *e.g.* Paper No. 12 on Scotland, 24 pp., 4*s.* 2*d.* for 50 copies.

ARRANGEMENTS for courses of instruction in anthropology for the coming session are announced by the University of Paris. In view of the bias towards practical application in Colonial administration which is a feature of the work of the recently founded Institut d'Ethnologie, it is interesting to note that lectures are to be given there, beginning in late December or January, on descriptive ethnography by M. Mauss, descriptive linguistics by M. Marcel Cohen, anthropology by M. Paul Rivet, and extra-European prehistory by M. l'Abbé Breuil. The special provinces of French administration are covered by courses on the linguistics and ethnography of Africa, lecturer not stated, owing no doubt to the lamented death of M. Delafosse, and the linguistics and ethnography of eastern Asia and Oceania. The courses at other colleges and institutions of the University cover a wide range: in physical anthropology, M. Verneau on the races of the French Colonies; in ethnography, M. Mauss on the religions of non-civilised peoples, with special reference to Australian rites; M. Raynaud on the archæology of Central America and Peru, M. Cabaton on the Malays, M. Capitan on American ethnic affinities, and origins, M. Julien on Madagascar, M. Labouret on East Africa, M. Milliot on Morocco, and others. In sociology there are seven courses, including lectures by M. Granet on the extreme East, M. Massignon on Islam, M. Cabaton on Indo-China, and a general course by M. Fauconnet. There are some twelve or thirteen courses in various languages, and a course in prehistory will be given by M. G. Renard.

DR. EDWARD R. WEIDLEIN, Director of the Mellon Institute of Industrial Research, University of Pittsburgh, has been elected president of the American Institute of Chemical Engineers for the year 1927.

WE have recently received the annual report of Livingstone College, Leyton, London, E.10, for the year 1925–26. The College exists to instruct missionaries in the elements of medicine, and seventy-seven students took the various courses. The College paid its way except for about £35, but a deficit of £1375 still exists. A fund is being established to the memory of Dr. Harford, the first principal, and donations to this and for the general purposes of the College are asked for.

THE Rockfeller Foundation has published a fourth series of "Methods and Problems of Medical Education," dealing with the methods of obtaining, assembling, filing, and storing the record of the sick person. After a study of several admirable systems, that of the Presbyterian Hospital of New York City is believed to combine the maximum of aims to be attained and is set out in full detail with many facsimile reproductions. It combines not only a full history of the case while in hospital, but also means for following up the after history of a case after discharge.

THE annual analysis of books published in the British Islands during the past year which is issued by the *Publishers' Circular* shows that the total number of books published in 1926, namely, 12,799, was 403 less than that for 1925. This decrease, however, was due entirely to the smaller number of new editions, the total of actual new books, 9989, being slightly greater than in 1925. The number of books on science increased from 617 to 660, and those on technology from 609 to 629, while medicine remained the same with 399 publications, and agriculture decreased from 208 to 184. Scientific books included 20 translations and 83 new editions. Dividing the literature of 1926 into twelve main groups, fiction heads the list with the most publications, while science comes sixth and technology seventh. In 1914, science was third and technology fifth, and in 1925 the order was science seventh and technology eighth.

WE have received from Messrs. James Swift and Son (81 Tottenham Court Road, London) their catalogue of microscopes and accessories. Of microscopes, four models are constructed according to the specification of the British Science Guild; the 'Didaxis' is of new design, combining simplicity with strength and rigidity, and eminently suitable for students' use; the 'Universal Technical' is a high-class instrument particularly adapted for research work of all kinds. Two oil-immersion lenses of low aperture are catalogued, an $\frac{1}{8}$-in. N.A. 0·92 and a $\frac{1}{12}$-in. N.A. 0·95, which have been primarily designed for use with dark-ground illumination.

AMONG the works to be published early in the new year by the Cambridge University Press are "The Collected Papers of Sir James Dewar," in two volumes, edited by Lady Dewar, J. D. H. Dickson, H. M.

Ross, and E. C. Scott Dickson. The work will include not only the papers which appeared under Sir James Dewar's name alone, but those also which were published jointly with other investigators, excepting the series on spectroscopy by him and Prof. Liveing which have been issued separately. The same publishers also announce "Differential Geometry of Three Dimensions," by Prof. C. E. Weatherburn; Volume 2 of the second edition of "Principia Mathematica," by Prof. A. N. Whitehead and the Hon. Bertrand Russell; and a new volume in the series of Cambridge Mathematical Tracts, "The Theory of Integration," by L. C. Young.

The Report of the Director-General of the Ordnance Survey for 1925–26 has recently been published. In trigonometrical work a field section is at work restoring the primary and secondary trigonometrical stations and marking them by concrete blocks. This has been completed south of a line between the Wash and the mouth of the Severn. Good progress has been made with the work of recomputing the co-ordinates of the primary and secondary trigonometrical points on the Gauss conformal projection. A revision of the magnetic survey of Great Britain was begun in the Channel Islands. In map production the third revision of the one-inch map of England and Wales is complete, and of the 146 sheets, 145 have been published in the popular edition. The revision of the map of Scotland was nearly finished and 9 sheets of the popular edition were published. All sheets of the quarter-inch layer map are published, two more sheets of the revised half-inch map, and one out of three sheets of the new ten-inch map. Progress has been maintained in the revision of the six-inch map, which is now again being published in quarter sheets.

Applications are invited for the following appointments, on or before the dates mentioned:—Additional Research Fellows in the Department of Glass Technology, The University of Sheffield—The Registrar, The University, Sheffield (January 12). A laboratory assistant for photographic work, at the Building Research Station of the Department of Scientific and Industrial Research—The Director of Building Research, Building Research Station, Garston, nr. Watford (January 15). An assistant master, qualified in physics and mathematics, at the Royal Naval College, Dartmouth—The Headmaster of the College (January 26). A Warden of Goldsmiths' College—The Academic Registrar, University of London, South Kensington, S.W.7 (January 31). An assistant in entomology at the Pathological Laboratory of the Ministry of Agriculture and Fisheries at Harpenden—The Secretary, Ministry of Agriculture and Fisheries, 10 Whitehall Place, S.W.1 (February 7). A professor of anatomy in the University of Adelaide—The Registrar, University of Adelaide, South Australia (March 1). A physicist in connexion with the Linen Industry Research Association, to take charge of a section dealing with finishing problems—The Secretary, The Research Institute, Lambeg, Co. Antrim.

The brightness remains nearly constant, about mag. 12.

Mr. F. E. Cunningham supports the suggested identity with Spitaler's Comet 1890, vii., noting that Tisserand's criterion is satisfied.

Sunspot Activity, 1926–27.—The list of notable sunspots for the present year has already begun. A large spot, conspicuous also on account of its regularity of outline, was first seen during the last few days of December and was on the sun's central meridian in the forenoon of Jan. 1. The latitude of this spot was 7° S.; another large spot, also in equatorial latitudes, was reported in Nature of Dec. 25, 1926, p. 925. It is evident that large spot disturbances are now appearing within a comparatively wide range of latitude—a sure indication that the sun has entered upon the maximum phase of this cycle. Judging, however, from the average latitude of spots and faculæ of the past year, the highest peak of the curve will not be reached before the end of 1927. The spots of 1926 were considerable and show an increase in mean daily area of about 50 per cent. greater than that of 1925. Eleven groups of spots, large enough to be seen with the naked eye, were reported in these columns at the time of their respective appearances, but there were at least half-a-dozen other groups of almost equal importance.

Particulars of the recent spot are as follows:

No.	Date on Disc.	Central Meridian Passage.	Latitude.	Area.
1	Dec. 26–Jan. 7	Jan. 1·3	7° S.	1/1200 of sun's hemisphere.

Another Repetition of the Michelson-Morley Experiment.—Mr. Roy J. Kennedy describes in the November issue of the *Proc. U.S. Nat. Acad. Sciences* a repetition of this experiment. He reduced his light path to 4 metres (one-sixteenth of that employed by Prof. Dayton Miller), and enclosed the apparatus in an air-tight case, filled with helium at atmospheric pressure, thus reducing the disturbing effect of density changes to one-tenth of that in air. A further device used was raising one half of the surface of his mirror a small fraction of a wave-length, which was effected by cathode deposition of platinum. Experiments were made both at the Norman Bridge Laboratory, Pasadena, and in the 100-inch telescope building at Mt. Wilson. Observations were made at various times of the day, but most often at the time when Prof. Dayton Miller's conclusions would require the greatest effect. The effect at both stations was absolutely *nil*: "there was no sign of a shift depending on the orientation." Mr. Kennedy claims that a shift one-fourth of that announced by Miller would have been detected, and states that he will make further experiments to search for a possible shift in other directions.

Research Items.

Diffusion or Invention in Culture.—In *Psyche* (Oct. 1926), Dr. Bronislaw Malinowski has a most illuminating article on the life of culture, in which he attempts to show that the contrast insisted upon by some anthropologists between culture by 'diffusion' or by 'invention' is erroneous. He points out that every modern invention is made and re-made time after time in different places by different men. In the case of 'wireless,' though the invention is popularly ascribed to Marconi it can be traced back through Ampère, Faraday, Righi, Braun, Clerk Maxwell, Hertz, Lodge, and other workers. Thus the invention of radio communication can be treated as a single and singular event and ascribed to one man or another only by a misconception: the point of view of the Patent Office cannot rightly be taken up for the science of culture. Every cultural achievement is due to a process of growth in which diffusion and invention have equal shares. Culture is something always at work, which is there for the satisfaction of elementary human needs, which in turn creates new wants and provides means for their fulfilment. The value of so-called savage 'superstition' is to be found in the confidence that magical rite gives man in forgetting difficulties and in bridging gaps in his knowledge. Borrowing from others does take place, but whenever one culture borrows from another, it always transforms and readapts the objects and customs borrowed. Diffusion is modified invention, exactly as invention is a partial borrowing.

Puzzle Crazes.—In the *Nineteenth Century* (Dec. 1926) there is an interesting account by Mr. Henry E. Dudeney of puzzle crazes, with particular reference to the recent popularity of the 'cross-word puzzle.' He traces the development of pastime puzzles from very early days. One of the very oldest is what is now called the 'tangram,' known to the Chinese thousands of years before the Christian era. The Egyptians, too, were fond of puzzles, and there is in the British Museum a treatise of this nature called "Directions for knowing all Dark Things." Coming to more recent times, Niccola Fontana in the sixteenth century published a number of puzzles, some of which are still popular. Mathematical puzzles have interested numbers of people for centuries, while innumerable puzzles have been devised with string, matches, and coins. The word puzzles are for the most part restricted to the particular language in which they appear, and hence lack the universality of those of the mathematical type. Real puzzle acrostics do not appear earlier than the nineteenth century, but they were apparently popular at the court of Queen Victoria. Although puzzles, verbal or otherwise, have always been attractive, yet the popular craze for a particular type would seem to be modern, since it is dependent on easy locomotion, the Post Office, and cheap journalism. The 'cross-word' is not in its nature new, but in its present form it had its first success in the United States. The 'cross-word' is convenient in form, no apparatus being involved; each item can be complete in itself, *i.e.* one need not finish the whole puzzle at one sitting, and hence it is admirably adapted to modern forms of transit; it can be done in groups and hence is not a bar to sociability; there are an infinite number of possibilities, yet one does improve with practice; the habit is easily fixed, and there is constant challenge and stimulus. Sooner or later, the author thinks, the inveterate solvers will have acquired such a large and extended acquaintance with the words of the language that they will want something else. Then the 'cross-word' will end for this generation.

The Treatment of Syphilis.—Mercury has long been known as an effective drug in curing the obvious symptoms of active syphilis. Its use for this purpose has, however, been almost entirely given up since the discovery of the far more efficient salvarsan. Nevertheless, in some clinics it has been the custom, when all signs of the disease have been cured and the Wassermann reaction made negative, to follow up salvarsan treatment with a prolonged course of mercury in the hope of finally killing off any residual spirochætes and converting what may be a quiescent infection into a complete cure. In a very thorough study of the results of this procedure in 711 cases treated in Liverpool (Medical Research Council: Special Reports Series, No. 107. London: H.M.S.O., 3*s*. 6*d*. net), Prof. E. E. Glynn, Dr. R. E. Roberts, and Mrs. Bigland show clearly that mercury given in the later stages not only does not prevent relapses, but even actually encourages them. There is no evidence to show whether this is due to the breeding out of strains of the parasite resistant to mercury or to depression of the general health and resistance of the body; but it is an important practical point and raises some curious questions in pharmacology.

Acclimatisation and High Altitudes.—In his recent ascent of the peak of Kibo, the summit of Kilimanjaro, Mr. D. V. Latham was able to make some valuable observations on the physiology of the human body in high altitudes in the tropics. These observations, together with an account of the climb, are published in the December number of the *Geographical Journal*. The peak is 19,710 feet in altitude. Shortness of breath was felt first at 12,000 feet, but was never distressing even at 19,000 feet, and it was noticeable that the body became acclimatised to respiration in reduced pressure. At 18,000 feet, on the fourth day of the climb, breathing was less difficult than at 15,000 feet on the first day, but above 18,000 feet, especially when the gradient was steep, it was necessary to stop and rest after every forty paces. The pulse rate during rest at varying altitudes was not markedly altered and the blood pressure did not vary. Muscular power was diminished at 19,000 feet, where even slight efforts meant appreciable fatigue. Mental processes were also slow at the summit. Mountain sickness in one of the climbers did not appear until 19,000 feet, and in another it became so severe at 15,000 feet that he had to descend 3000 feet for two days' rest, after which he climbed to 17,200 feet before the symptoms returned. Mr. Latham believes that this difficulty can be overcome by gradual acclimatisation, and he does not think that it is due to oxygen-want, since the sickness was always relieved by walking, when the oxygen demand was greater than when resting. The paper contains also some interesting observations on red blood cells at different altitudes.

Asexual Reproduction without Loss of Vitality in the Organism of Bird Malaria.—Prof. R. W. Hegner (*Science*, 63, pp. 479, 480, 1926) records that *Plasmodium praecox*, the organism of bird malaria, has been met with several times in the United States in the common English sparrow. Whitmore in August 1913 obtained this organism from sparrows in New York and inoculated it into canaries, and Hegner obtained this strain in 1918 and has maintained it in canaries in his laboratory. In 1924 another strain was obtained by Hartman from a sparrow in Baltimore, and this also has been maintained in canaries. The asexual cycle of the New York strain has been shown to be thirty hours and that of the Baltimore strain twenty-four hours; whether the period of the former has become longer during its extended cultivation in canaries is not known. The number of asexual generations passed through by this strain since August 1913 is more than 3600. The Baltimore strain has passed through about 550 asexual generations and the periodicity seems to have been maintained unchanged, and this may be regarded as a measure of its vitality. Both the strains have maintained their virulence throughout the entire period. Prof. Hegner directs attention to the interest attaching to the rate of reproduction and to the virulence of these organisms living in a constant environment.

CRYSTAL STRUCTURE IN BIOLOGY.—Of considerable interest to biologists is last year's Mather Lecture of the Textile Institute delivered by Sir William Bragg on "The Fine Structure of Animal and Vegetable Substances as Revealed by the X-rays" (*Journal of the Textile Institute*, vol. 17, No. 11, Nov. 1926). The method used in the analysis of crystal structure has been applied to the study of cotton and wool fibres. In the case of ramie fibres the X-rays reveal the presence of multitudes of very minute crystals with some regularity of internal arrangement, in that a certain axis of each crystal is oriented along the main axis of the fibre. Otherwise the crystals are in complete disarray. Herzog (*Journal of Physical Chemistry*, April 1926, p. 457) found the unit pattern of a ramie fibre to be contained in a right-angled 'cell' calculated to weigh four times as much as the actual molecule of cellulose; so that the crystalline structure of the fibre is really very simple, and formed by the repetition of a fundamental unit of pattern containing only four cellulose molecules. The structures of such diverse materials as sugar crystals, rubber, and even chain compounds like fatty acids, have been analysed in the same way. From the point of view of the biologist, this is getting vegetable structure down very fine, and the method opens up a new avenue of approach to the investigation of at least some types of histological and causal problems (see also NATURE, July 24, 1926, p. 120).

THE ORIGIN OF FJORDS.—The vexed question of the origin of fjords was dealt with by Prof. J. W. Gregory in a lecture on the fjords of the Hebrides to the Royal Geographical Society on Dec. 20. While not denying that ice may have played a part in moulding the shape of fjords, Prof. Gregory insisted that other origins must be found for the valleys themselves. He pointed out that the direction of the fjords has no particular relation to the grain of the country, and that the main flow of the ice sheets was frequently across, and not along, the fjords. Fjords originated in rents or fissures due to earth movements. The nature of the earth movements gives a classification into three divisions. First are the rift valleys, due to the sinking of a strip of land between parallel faults; secondly are those valleys, due to a shattering of belts of rock by many tension clefts and the removal of the material by wind, water, and ice; and thirdly, the fjords due to the subsidence of a strip of country against one major fault producing an asymmetric valley. Prof. Gregory attributes the fjords of the Hebrides, like the sea lochs and fresh-water lochs of western Scotland, to the indirect effects of the Alpine folding of Oligocene and Miocene times, and the later Atlantic subsidences. To the Alpine movements was due the rending of the earth's crust, and to the later uplift of the British area was due the gaping of the fissures. The action of the surf along the shore and of erosive agencies inland has since modified these tectonic valleys.

BITUMINOUS SANDS OF NORTHERN ALBERTA.—A further report by Mr. S. C. Ells, of the Mines Branch, Department of Mines, Canada, describes his investigations of the well-known impregnated sands of the Fort McMurray region, on the Athabaska River, northern Alberta, up to the end of 1924. Although the deposits are very extensive, occupying more than 2000 square miles, not more than 3 square miles are readily accessible for commercial exploitation; the rest of the deposits lie beneath a thick overburden and would thus prove relatively expensive to operate. The percentage impregnation varies between 12 and 15, occasionally higher in limited areas. The report gives concise information on the character of the sands, also results of numerous laboratory determinations and analyses. Possibilities of economic development are considered, especially with reference to sources of fuel, power, transportation, markets and climatic conditions under which work would have to be prosecuted. Various processes have been designed to extract the bitumen from the sands, and for utilising the raw material in its natural condition; some of these processes are capable of extension and improvement to adapt them to large-scale operations, others are in the more experimental stage; all important ones, however, are reviewed in the report (No. 632), a document of 244 pages fully illustrated with photographs and diagrams. In addition there are 8 detailed maps and 4 cross-sections; the latter show the relative position of the sands with reference to overlying strata and the trend of present topography. After all the careful field and laboratory investigation which these Athabasca 'tar-sands' have received, particularly at the hands of the author, it will be very disappointing if at least a portion of the available resources cannot be profitably worked.

VACUUM TECHNIQUE.—The issue of the *Physikalische Zeitschrift* for November 1 contains an article of 20 pages by Mrs. M. A. Shirmann, of the Physical Institute of the University of Vienna, on two improvements which have been introduced recently into the technique of high vacua. When a vessel has been exhausted and has to be sealed off from the pump, the sealing process sets free from the heated surface of the glass a certain amount of gas which in general, as the seal is close to the vessel, gets into the vessel. By connecting the vessel to be exhausted by a narrow tube to the trunk tube of the pump and sealing off close to the trunk, only a small proportion of the gas liberated gets into the vessel. The second improvement relates to ground glass joints and to taps in which the seal is effected without mercury or grease. In the case of a joint, the inner cone may be metal or, if not, its outer surface is coated with metal; the outer cone has metal deposited on its outer surface, and between the two metal surfaces an electromotive force is applied which draws the two surfaces together. In the tap the plug is of metal, the outer surface of the barrel is coated with metal, and an electromotive force applied between the metals.

DECAY OF FLUORESCENCE.—In the *Ann. des Phys.*, No. 23, p. 681, 1926, E. Gaviola describes an interesting application of the Kerr phenomena. He shows that a satisfactory electro-optical arrangement may be devised to perform the function of the toothed wheel in Fizeau's measurement of the velocity of light. With this arrangement he has been able to show experimentally, for the first time, that stationary waves, established by a Lecher wire system, possess the wave-lengths predicted by Maxwell's theory. The main purpose of the method, however, was to investigate the rate of decay of the fluorescence of solutions of dyes, and Gaviola finds that the average duration of the fluorescence of solutions of rhodamin B and of uranin in glycerine and in water is of the order of 10^{-9} second. The effect of concentration on the rate of decay, if such an effect exists, appears to be very small.

The Pretoria Meeting of the South African Association for the Advancement of Science.

THE twenty-fourth annual meeting of the South African Association for the Advancement of Science took place at Pretoria on July 5-10, 1926, under the presidency of Dr. E. T. Mellor. The meeting was very well attended, and 129 papers were read. Joint meetings of several sections were held. A popular lecture was given by the Hon. J. H. Hofmeyr, Administrator of the Transvaal, on "The Romance of Ægean Archæology." There was a reception by the Mayor and Mayoress of Pretoria, a conversazione by the Pretoria branch of the South African Biological Society, and visits to various places of scientific interest in the neighbourhood.

The president, Dr. E. T. Mellor, in his address, gave an account of "Science in Relation to Mining and other Industries in South Africa." He indicated how modern scientific thought and methods have entered into the everyday life of the people instead of being restricted to the laboratory. The Witwatersrand goldfield, he said, is probably the most concentrated and important one in the world, and in the development of South Africa, gold and diamond mining has played a very important part. Gold being stabilised in price, and with an unlimited market, permits friendly rivalry in efficiency of mines. Geology has benefited from mining through the study of auriferous conglomerate and the origin of gems. Deep-level mining yields information on rock temperatures at great depths. In physiology the effects of moisture and temperature on health have been studied. In pathology the study of respiratory diseases has been of greatest general benefit. Anthropology even has benefited as a result of mining. The discovery of deposits of platinum is the result of a geological survey. The importance of industrial research was indicated, and, in concluding, the president pointed out that science is not local but universal, and commended it as a life career of greatest interest.

"The Problem of Atmospheric Electricity" was chosen by Prof. P. G. Gundry for his presidential address to Section A. In speaking of pure and applied research, he stated that it is scarcely too much to say that no great forward step is ever made without being based on the work of those spurred by scientific curiosity alone. The place of South Africa in pure research such as astronomy is largely due to amateurs, to whose work also much of our knowledge of the electrical condition of the earth and its atmosphere is due. The Heaviside layer of the atmosphere, radio telegraphy, and the earth's electric field were discussed at length, as was recent work on very penetrating rays of cosmic origin. Ionisation of the air and Wilson's work on thunderstorms were described, and the suitability of South Africa for the study of thunderstorms was indicated.

Dr. St.C. O. Sinclair gave an account of "The Chemical Service of the Union of South Africa: its Organisation and Work" as his presidential address to Section B. This service is distributed between the staffs of the Division of Chemistry, the Schools of Agriculture, the Veterinary Research Institute and an industrial chemist. The Division of Chemistry has to undertake work for State departments, such as agriculture, justice, finance, public health, mines, posts and telegraphs. The staffs of the schools of agriculture act as research officers, teachers and extension officers. Biochemical problems and poisonous plants are dealt with at the Veterinary Research Institute. The systematic soil survey of the Union, brak investigation in relation to irrigation schemes, fertiliser experiments, the making of synthetic manure, investigation of the composition of fruit and its export under the best conditions, preservatives, tanning materials and prickly pear destruction were all discussed. The scope of the regulatory work of the Government Division ranges from work on food adulteration to the preparation of chaulmoogra oil esters for the treatment of leprosy.

The subject of Prof P. A. van der Bijl's address to Section C was "Landmarks in the Development of the Science of Plant Pathology and Disease Control." Researches on fungoid diseases of plants, dealing with life-histories, biological races, disease resistance, mechanism of penetration by parasites and variations under environmental conditions, were discussed, as were bacterial plant pathogenes. Mosaic and protozoal diseases were also considered. The history of control measures against plant diseases was given and their importance indicated. The attention given to the study of plant diseases in different countries was noted, and the advantages to a country of systematic instruction through university training in plant pathology, as in America and South Africa, were indicated.

The presidential address to Section D was delivered by Prof. C. G. S. de Villiers, his subject being "Some Aspects of the Morphology and Ontogeny of the Skeletogenous Strata." The need of correlation of comparative anatomy, comparative embryology, phylogenetic palæontology and experimental zoology in investigations of the morphology of the chordates was first indicated. Neoteny was discussed and the origin of the mesodermal skeleton reviewed fully. The differentiation of the mesenchyme and the various views on the morphology and origin of the sternum in Amphibia were indicated. The ontogeny of the tissue giving rise to the zonal and appendicular skeleton is as yet unknown, though probably mesenchymatous. The nature of membrane bones requires further investigation. Phylogenetically, membrane bones are older than cartilage bones, and whether they acquire secondary relations to zonal, sternal, cranial or visceral skeleton, they are remnants of the original exoskeleton. Ontogenetically they may be derived from the cutis layer of the myotome. The use of the experimental method was noted. The solution of many obscure problems in osteology can only be solved when a clearer knowledge is obtained of the earliest differentiation of the mesodermal skeletogenous strata.

"The Need of a Scientific Basis for South African Native Policy" formed the subject of Mr. J. D. Rheinallt Jones's presidential address to Section E. Students of native policy in the past have been largely guided by historical considerations leading to partisanship. New lines of research are needed. The primitive mentality of natives needs careful study to determine if qualitative differences between the European and Bantu mind may be present. Levy-Bruhl's hypothesis of total difference in orientation of the native mind from that of the European was discussed. There appears to be something incompatible between the foundations of primitive culture and those of modern civilisation, but this does not necessarily prove that the difference is absolute and not one of degree. The modes of alteration of primitive mind were discussed, as was animism and its effects. The necessity for anthropological and psychological research was stressed.

Dr. S. Evans discussed "The Politician and Political Economy" in his presidential address to Section

F. The present misfortunes of many countries are, he said, due to ignorance and contempt for elementary economic principles by responsible authorities during and since the War. Lack of experience in subject or administration is no disqualification for ministerial responsibilities. Rhetorical idealism still has more power over the mind than knowledge or reason, and rhetoricians become ministers with power to interfere with the conduct of industries and commerce, of which they know nothing. The primary producers always suffer most from ignorance of the principles of political economy by those in power, and by support of sheltered industries at their expense. Europeans are not coming for agriculture to South Africa, as conditions which repel the capitalist have been created, and over-taxation of the mining industry has checked them and curtailed the profitable operation of gold. The probable life of the Witwatersrand goldfield was discussed. Johannesburg is becoming more independent of the mines, but their decreased spending power will affect the whole of South Africa adversely, unless made good by expansion in some other direction. The necessity of a policy to foster private enterprise and to introduce foreign capital and European immigrants for development of industries was urged.

The next annual meeting of the Association will be held under the presidency of Prof. H. B. Fantham, professor of zoology in the University of the Witwatersrand, Johannesburg, Transvaal, at Salisbury, Southern Rhodesia, in July 1927.

[The above brief summaries of the presidential addresses to the sections were sent by Prof. H. B. Fantham, who included also the names of authors and the subjects of papers read before the various sections. We regret that limitations of space prevent us from printing this account of the sectional proceedings.—ED. NATURE.]

The Fisheries of Ceylon.

DETAILS of the marine biological research carried out by the Ceylon Government are contained in the reports for 1924[1] and 1925.[2] In the first of these reports is an account by Commander J. C. Kerkham, the Marine Superintendent, of the Government research vessel *Nautilus*. This, a German-built steam trawler 132 feet in length, has been fitted out with laboratory accommodation and apparatus for carrying out scientific trawling, dredging, and hydrographic investigations. In addition she is equipped with a steam-driven, direct-expansion ammonia refrigerating plant with two insulated chambers for the storage of fish.

A biological survey, commenced in 1920 by the Government trawler *Lilla* and continued by the new trawler, has been fruitful in disclosing the possibilities of two fishing banks, the Wadge and the Pedro: some results of a survey of these banks are given by Dr. Pearson and his assistant biologist, Mr. Malpas, in the 1924 report, and more details are now given in a further paper.[3] The banks give a combined area of 3000 square miles, with an average depth of 25 to 50 fathoms. The advantage to be gained by the employment of two steam trawlers by the Government is shown, calculations being based on a conservative estimate of 1¼ tons and 1¼ tons of fish caught per diem for the respective banks. Steam trawling should not seriously affect the fisheries of the native fishermen—not only because the grounds are too far afield for them, but also because they fish chiefly for drift-net and line-caught fish that are not captured in the trawl. In 1925 actual catches were carried to Colombo in the cold-storage chambers of the research steamer, and it was demonstrated that the fish arrived in good condition and that a ready sale was obtained for them. It is considered that if an assurance of a steady supply of fresh fish could be guaranteed to passenger shipping using Colombo as a port of call, the present spasmodic demand made by them would become regular; and it is believed that the prosperity of the trawling industry would depend on the measure of support given by the shipping. The employment of up-to-date fishing methods is therefore urged.

In somewhat less hopeful vein comes the report for the Pearl Fisheries of 1925,[4] in which is an interesting account by Dr. Pearson of the previous scientific investigations from the time of the late Sir William Herdman's survey in 1902 to the present day. Dr. Pearson critically reviews the situation and puts forth his own views on the matter. The pearl fisheries in the past have been essentially intermittent, only 39 fisheries having taken place in 125 years. It was such fluctuation that was responsible for the failure of the ill-fated Ceylon Company of Pearl Fishers that started operations in 1905, burdened amongst other things with the pledge to spend between £3000 and £10,000 annually on cultural and experimental research. It has been the aim of scientific inquiry to seek the causes of this irregularity and hence, if possible, a remedy, so as to ensure a productive regularity in the industry.

Chief among the suggestions put forward has been that of the employment of cultural methods such as those used in the oyster industry of Arcachon. Dr. Pearson takes the view that previous workers have been unduly optimistic in their hopes and considers that the site and conditions of the Ceylon pearl fisheries are such that cultural methods *in situ* are out of the question, and that the fisheries must mainly be controlled by natural agencies. In this he is probably right, seeing that the pearl oyster is essentially a deep-water shellfish compared with the Portuguese oyster at Arcachon, which lives in the tidal zone. The fact that the pearl-oyster grounds are extremely narrow may be of great significance in the irregularity of the supply, since the two maximal spawning periods occur when the south-west and north-east monsoons are respectively at their highest, and the pelagic larvæ may be carried far from suitable ground by currents. To control the fall of spat in the open sea is beyond human power. As James Steuart said in 1843: "It is only when, in the infinite wisdom of the Creator of all things, the oyster brood descends upon the banks suited to nourish and support it . . . that it comes within our power to watch its advancing age . . ."

However, given a successful spat fall a good fishery is not necessarily ensured; in late life the oyster beds are liable to decimation, as Dr. Pearson shows by figures for the crops in recent years. Two of the greatest dangers to the growing crop are perhaps the action of currents, which may uproot the oysters from the ground or carry sand which becomes deposited and silts up the beds, and the inroads of such shellfish-eating fish as rays, a species of which, incidentally, carries one stage of the parasite that infects the oyster and so gives rise to pearls.

---

[1] Ceylon Administration Reports for 1924. Part 4: Education, Science and Art (F).

[2] Administration Report of the Government Marine Biologist for 1925. By Dr. Joseph Pearson. Pp. F16. (Colombo: Government Record Office) 35 cents.

[3] Sessional Paper 14, 1926. Prospects of Trawling in Ceylon. Pp. 12. (Colombo, Government Record Office.) 20 cents.

[4] Ceylon. Sessional Paper 15, 1926: Reports on the Pearl Fishery of 1925 By Dr. Joseph Pearson. Pp. 80+11 plates (Colombo: Government Record Office) 1·25 rupees.

This is not to say that research in the past has been valueless nor that it is no longer necessary. It is very evident that scientific investigations are of the utmost importance in watching the histories of the various beds and deciding the most economic periods at which to fish them. There would still seem to be room, too, for a more detailed study of the habits and conditions required for the successful development of the oyster in the laboratory on the lines of the work now being carried out by the Ministry of Fisheries in Britain in its oyster research station at Conway.

The fishery in 1925, which appears to have been unfortunate owing to the failure of many divers to arrive at the beginning and to unfavourable weather conditions, brought in a net profit of Rs.1,67,017.

Interesting data on the growth of the pearl oyster are given; information arising from a number of linear measurements and weight determinations tends to lower the previous estimates of the ages of different-sized oysters.

It is gratifying to note that the staff of marine biologists attached to the Ceylon Government is growing, and we hope for much information of interest on tropical marine life in the future. F. S. R.

University and Educational Intelligence.

CAMBRIDGE.—Prof. A. E. Taylor of the University of Edinburgh has been appointed Leslie Stephen lecturer for the year 1927. Mr. H. Claye, Gonville and Caius College, has been appointed an Assistant Registrary.

Application should be made before June 1 to the Senior Tutor, St. John's College, by any graduate of another university seeking admission as a research student who wishes to be a candidate for the Strathcona Research Studentship of £150 a year at St. John's College.

The entrance scholarships and exhibitions awarded at twelve colleges at the end of last term include 33 for mathematics and 33 for natural sciences out of a total of 169 awards; other awards were 54 for classics, 24 for history, and 21 for modern languages.

LONDON.—The following courses of free public lectures are announced: "Current Views on Internal Secretion," by Prof. Swale Vincent, at the Middlesex Hospital Medical School, on Jan. 14, 18, 21, and 25, at 4 o'clock; "Biological Action of Light," by Dr. D. T. Harris, at University College, on Jan. 20 and 27 and Feb. 3, at 5 o'clock; and "Cytology in relation to Physiological Processes," by Dr. R. J. Ludford, at University College, on Jan. 20 and 27, Feb. 3, 10, 17, and 24, at 5.30 o'clock.

Mr. E. Matthews has been appointed demonstrator in the Chemistry Department of Guy's Hospital Medical School.

STATISTICS of universities, colleges, and professional schools in the United States are published biennially by the Federal Bureau of Education. In the 913 institutions which figure in the returns for 1923–24, published in *Bulletin* No. 45, 1925, the total number of students enrolled in that year amounted to 726,124, including 268,423 women. Of the 913 institutions, 144 were under public control, and these enrolled 255,630 students, of whom 88,770 were women, whilst privately controlled institutions enrolled 470,494, of whom 179,653 were women. There were also enrolled 189,943 additional students in summer schools, 4012 in winter short courses, and 140,846 in extension and correspondence courses. Turning back to the similar bulletin issued two years ago, one finds that the number of institutions reporting was then only 780. The addition of 133 reports "is due in part to the efforts of field agents of the Bureau of Education, who secured many reports by personal visits." This detracts somewhat from the value of the statistics for purposes of comparison of one period with another, and points to the futility of the comparisons that are sometimes made between the student statistics of different countries.

THE Report for the year 1925 of the Calcutta School of Tropical Medicine, Institute of Hygiene, and the Carmichael Hospital for Tropical Diseases, contains, in addition to a review by the Director, Lieut.-Col. J. W. D. Megaw, of the work carried out at the School since its opening in November 1920, a list of articles (nearly a hundred) published by members of the staff during the year, separate reports of the specially endowed researches in relation to kala-azar, hookworm, bowel diseases, leprosy, and diabetes, reports by the Superintendent of the Pasteur Institute (which has been so fully employed in the treatment of patients that it was unable to undertake research) and by professors in charge of departments. The School is said to be the only institution in India adequately equipped for post-graduate teaching of tropical medicine and hygiene, and for training young medical research workers, and, as such, it serves the needs of the whole of the Indian Empire. The endowment fund amounted at the end of the year to more than eleven lakhs of rupees (nearly £90,000), and the receipts of the year included an anonymous donation of one lakh of rupees, in addition to handsome contributions by the commercial communities of eastern India and by Indian noblemen and merchants. The expenditure of the year amounted to Rs.1,19,904, of which Rs.1,02,834 was on account of salaries.

THE Departmental Committee on Education and Industry appointed by the Minister of Labour and the President of the Board of Education jointly, has issued an interim report dealing with the machinery available "for enabling young persons to enter into and retain suitable employment." The principal elements of this machinery are the juvenile employment committees of those local education authorities which have decided to exercise their powers under the Choice of Employment Act and the juvenile advisory committees, appointed by the Ministry of Labour, in areas where no such decision has been taken. Since 1921 the administration of unemployment insurance for boys and girls up to the age of 18 years has been linked with the choice of employment work, so that one and the same local authority must be responsible for both. One of the chief recommendations made in this report is that central responsibility for both should likewise be vested in one and the same authority, namely, the Ministry of Labour, instead of being shared, as at present, with the Board of Education. Other recommendations are: To consider the setting up of a National Advisory Council for Juvenile Employment, on which local education authorities should be strongly represented; to encourage the application of psychological tests; to cause a special inquiry to be undertaken regarding the transfer of juvenile labour from one area to another; to establish a scheme for juvenile unemployment centres on a permanent basis; and not to permit either recourse to compulsion to secure the attendance of unemployed juveniles of 14 years and 15 years at courses of instruction, or the payment of maintenance allowances to juveniles attending unemployment centres or other approved courses.

Calendar of Discovery and Invention.

January 9, 1729.—While holding the Savilian professorship of astronomy at Oxford, Bradley attempted to detect the annual parallax of the fixed stars. Hooke at Gresham College, and Molyneux at Kew, attacked the same problem, and Bradley collaborated with the latter. He then erected a zenith sector at Wanstead. The observed movement of the stars for a time baffled him, but after much thought he was able to explain what he saw by his important discovery of the aberration of light; a discovery which was communicated to the Royal Society on Jan. 9, 1729, in the form of a letter from Bradley to Halley.

January 10, 1849.—Some of the earliest experiments in submarine telegraphy were made by Wheatstone, Sömmering, Morse, and Colt, but it was the introduction of the use of guttapercha by Werner Siemens which made submarine cables practicable. On Jan. 10, 1849, C. V. Walker, of the South-Eastern Railway, laid two miles of cable in the Channel off Folkestone, and by this and a land line of 83 miles communicated from a ship with London. There are now more than 300,000 miles of submarine cables in use.

January 11, 1816.—It was the terrible explosion at Felling Colliery, near Sunderland, in May 1812, which led to the formation of a Society for Preventing Accidents in Coal Mines through which Davy's attention was attracted to the subject. His investigation of the properties of fire-damp and the passage of flame through tubes, and his invention of the wire-gauze safety lamp, were described to the Royal Society on January 11, 1816. Many improvements in miners' lamps have been introduced since, giving greater safety and more light. In 1924 it was recommended that lamps should have 0·8 candle-power, and in recent years electric lamps have been largely adopted.

January 12, 1727.—On this day two hundred years ago died Jacob Leupold, of Saxony, famous for his skill in constructing mathematical instruments and machines. His great work, "Theatrum Machinarum," was published in 1723-1727. The contemporary of Savery and Newcomen, Leupold was the first to suggest a high-pressure steam engine. His sketch shows an engine with two pistons working two force pumps through beams, the distribution of steam being controlled by a four-way cock.

January 13, 1800.—Founded through the instrumentality of Rumford, the Royal Institution was incorporated on Jan. 13, 1800. The name Institution was adopted in imitation of the Instituto of Bologna, while its purpose was "for diffusing the knowledge and facilitating the general introduction of useful mechanical inventions and improvements, and for teaching, by courses of philosophical lectures and experiments, the application of science to the common purposes of life." Its early development as a research institution was due to Davy and Faraday.

January 15, 1876.—In the Science Museum, South Kensington, is preserved the apparatus with which Andrews, of Belfast, made his famous experiments on liquids and gases and discovered the existence of a critical temperature. His work was done in the 'sixties. Writing to him on January 15, 1876, Kelvin said: "We are all greatly delighted in my laboratory with what you have given us—my old assistant MacFarlane is in raptures to see carbonic acid compressed to the liquid state in that always ready way. It will be a splendid lesson to my students, and I think that henceforth they will every lesson know more of the meaning of liquids and gases and vapours than I have ever been able to teach them." E. C. S.

Societies and Academies.

LONDON.

Royal Microscopical Society, November 17.—**M. T. Denne**: A new apparatus for casting paraffin imbedding blocks. It consists of a jacketed chamber in the upper surface of which troughs are formed, fitted with frames or 'lifters,' and adapted to receive the wax. A second reservoir contains water heated to a definite temperature by gas or electricity, and this is so arranged that it may be raised to fill the jacketed chamber or lowered to empty it. In operation, the hot water is caused to enter the jacketed chamber, the troughs are filled with melted paraffin, and the objects arranged in the ordinary way or oriented under a Greenough binocular, the paraffin being maintained at the correct temperature meanwhile. When ready, the reservoir receives the hot water, and cold from a main supply is forced into the jacket causing very rapid cooling. A second momentary application of the hot water from the reservoir frees the blocks by superficial melting, and they are lifted out of the troughs.—**C. Tierney**: Caballaro's technique for mounting diatom and other type slides. The method consists essentially in manipulating the specimens with a fine hair in a hermetically sealed chamber attached to the microscope. A petri dish with a raised platform in the centre, on which the specimens and prepared cover-glass are placed, is filled with mercury. From the nosepiece of the microscope is suspended a wire carrying the hair and a glass cylinder which, when the body-tube is lowered, enters the mercury, thus forming a sealed chamber free from all air currents, condensation, and dust particles.

PARIS.

Academy of Sciences, November 22.—**Émile Borel**: A theorem on systems of linear forms with skew symmetric determinant.—**C. Matignon** and **Mlle. G. Marchal**: The heat of oxidation of beryllium. Starting with the pure metal prepared by the method of Stock, Praetorius, and Priess, the heats of solution in hydrofluoric and hydrochloric acids were determined, from which the heat of formation of beryllium oxide is deduced as 140·3 calories. Based on this figure, the heats of formation of various beryllium compounds have been recalculated.—**Georges Claude** and **Paul Boucherot**: The utilisation of the thermal energy of the sea. At depths of 1000 metres the temperature of the sea water is between 4° C. and 5° C., and in the tropics that of the surface between 26° C. and 30° C. The possibility of utilising this temperature difference to work a low-pressure turbine is discussed, and some experiments described in which a low-pressure steam turbine was made to work between the temperatures 0° C. and 28° C.—**Léon Guillet**: The addition of nitrogen to steel. In an earlier paper the case hardening of certain steels by the action of ammonia at 500° C. is described: the present communication gives measurements of hardness (Brinell) of these steels under varying conditions.—**Tilho**: The Nile at the borders of Tibesti near the centre of the Libyan desert (explorations of Prince Kemal el Dine).—**Paul Montel**: The domain corresponding to the values of an analytical function.—**Maurice Janet**: The possibility of plunging a given Riemannian space of n dimensions into a Euclidian space of $\frac{1}{2} n (n+1)$ dimensions.—**Léon Pomey**: The integration of a system comprising an infinity of ordinary differential equations with an infinity of unknowns.—**N. Podtiaguine**: Regularity of growth [of functions].—**A. Toussaint** and **E. Carafoli**: The kinematographic spectra of the plane flow of fluids round varied obstacles.—**A. Véronnet**: The rotation of a heterogeneous mass.

Evolution and fractionnation. The case of Jupiter and Saturn.—P. Helbronner: The twenty-first and twenty-second campaigns of the detailed geometrical description of the French Alps.—Th. Vautier: The increase of intensity and the duration of extinction of sound.—Léon Bouthillon: Radiogoniometers and radiophares with accentuated maximum.—L. Longchambon: The rotary power of tartaric acid. Discussion of a recent note on the same subject by E. Vellinger. Details are given of the changes in the rotary power of tartaric acid produced by dilution down to a concentration 0·00625. A tube 10 metres long was used in these measurements.—J. Galibourg and F. Ryziger: Contribution to the study of the Röntgen spectrography of pearls. A discussion of a Röntgen spectrograph as a means of distinguishing natural from cultivated pearls.—P. Mercier: The particles of long path emitted by the active B+C deposit of actinium.—Neda Marinesco: Some properties of large molecules in solution.—Charles Dufraisse and Paul Gailliot: Peculiarities of the fractures of acrolein gels: rhythmic production of ridges. Fractured surfaces of acrolein gels, examined under the microscope, show remarkable regularities, the surface being covered with parallel, equidistant straight lines resembling a ploughed field. These surfaces form a diffraction grating (about 120 lines to the millimetre) and give spectra both by transmission and by reflection. A spectrograph of mercury vapour obtained with such a grating is reproduced.—Tiffeneau and Mlle. J. Levy: The desamination of some phenyl-amino-alcohols, C_6H_5.CH(OH).CH(NH_2)R. Preparation of acylophenones without transposition.—Pierre Jolibois: The constitution of the organo-magnesium compounds. In an earlier communication (*C. R.*, 1912, p. 353) the author has given reasons for preferring the formula $Mg(C_2H_5)_2.MgI_2$ to the more generally admitted $Mg.C_2H_5.I$. Work for and against this view published since 1912 is summarised, and the work of Job and Dubien, which supports the formula $Mg.C_2H_5.I$, is adversely criticised.—V. Ipatief and N. Orlof: The hydrogenation of xanthone and xanthene.—Y. Altchidjian: The utilisation of liquid fuels containing a high proportion of organic sulphur compounds as a source of an antidetonating combustible. It is suggested that from the work of Midgley and Boyd, organic sulphur compounds might be expected to act as antidetonants in internal combustion motors: this conclusion has been confirmed by experiments with mixtures of petrol and heavy oils containing sulphur obtained by carbonisation of bituminous limestones.—N. Menchikoff: Primary strata to the south of Oued Drâa.—Const. A. Kténas: The chemico-mineralogical nature of the enclosure of Fouqué-Kaméni (Santorin).—Pierre Allorge: The benthos with desmids of the lakes in the west and centre of France.—Pierre Dangeard: The variation of the plates (carapace) in Peridinium.—J. Magrou: The anatomy of plant cancer or crowngall.—Raoul M. May: The reaction velocity of *Calliactis effoeta* in the presence of alkaloids and of gland extracts.—P. Delauney: The biochemical synthesis of a chlorinated glucoside, β-5 chlorosalicyl glucoside.

Official Publications Received.

British and Colonial.

The Manchester Museum. Museum Publication 92: The 'Behrens Collection of Sumerian Tablets in the Manchester Museum. By T. Fish. (Notes from the Manchester Museum, No. 30.) Pp. 6+12 plates. 1s. 6d. Museum Publication 93: Report of the Museum Committee for the Year 1925–26. Pp. 20. 6d. (Manchester: At the University Press; London: Longmans, Green and Co., Ltd.)

Third Annual Report of the Research Association of British Flour-Millers, 1925–1926 (July 1st to June 30th). Pp. 24. (St. Albans, Herts; London: 40 Trinity Square, E.C.3.)

Journal of the Indian Institute of Science. Vol. 9B, Part 3: Aerial Testing. By J. K. Catterson-Smith. Pp. 21-28+11 plates. 1.8 rupees. Vol. 9B, Part 4: Circulating Currents in Wave-wound Armatures. By F. N. Mowdawalla and G. K. Pradhan. Pp. 29-35+18 plates. 1.8 rupees. Vol. 9B, Part 5: Madras (Fort) Radio Field Intensity Measurements at Bangalore. By K. Sreenivasan. Pp. 37-50+12 plates. 3 rupees. (Bangalore.)

Union of South Africa: Department of Agriculture. Science Bulletin No. 50: Some Physical and Chemical Changes occurring during the Ripening of Grapes (Second paper). By P. R. v. d. R. Copeman and G. Frater. (Division of Chemistry Series No. 67.) Pp. 54. 9d. Science Bulletin No. 51: Factors Influencing Overrun. By D. J. Retief. Pp. 24. 3d. (Pretoria: Government Printing and Stationery Office.)

Aeronautical Research Committee. Reports and Memoranda. No. 1031 (M. 42): The Torsion of Circular and Elliptical Cylinders of Homogeneous Æolotropic Materials. By S. J. Wright. Work performed for the Engineering Research Board of the Department of Scientific and Industrial Research. (E.F. 176.) Pp. 5. 4d. net. No. 1035 (M. 44): Report on the 'Burning' of Aluminium. By J. D. Grogan. Work performed at the National Physical Laboratory for the Engineering Research Board of the Department of Scientific and Industrial Research. (B.1.a. Metals, Strength and Properties, 52.—T. 2306.) Pp. 12+3 plates. 1s. net. (London: H.M. Stationery Office.)

Splices and Tapes for Rubber Insulated Wires. Pp. 16. (Passaic, N.J.: The Okonite Co.; London Agents: Wm. Geipel and Co.)

List No. 148: Cambridge Dissolved Oxygen Recorder for Boiler Feed Water. Pp. 4. (London: Cambridge Instrument Co., Ltd.)

Diary of Societies.

FRIDAY, January 7.

Geologists' Association (at University College), at 7.30.—Dr. G. Slater: Glacial Tectonics as reflected in Disturbed Drift Deposits: Studies in the Drift Deposits of the South-Western Part of Suffolk. Part 2 and 3.

SATURDAY, January 8.

Royal Institution of Great Britain, at 3.—Prof. A. V. Hill: Nerves and Muscles: How we Feel and Move: (6) Speed, Strength, and Endurance.

MONDAY, JANUARY 10.

Royal Society of Edinburgh, at 4.30.—Frances M. Ballantyne: Air-Bladder and Lungs: a Contribution to the Morphology of the Air-Bladder of Fish.—Dr. G. Slater: (a) The Structure of the Disturbed Deposits of Møens Klint, Denmark; (b) The Disturbed Glacial Deposits in the Neighbourhood of Lønstrup, near Hjørring, North Denmark.—E. L. White: The Fish-Fauna of the Cement-Stones of Foulden, Berwickshire.

Institution of Electrical Engineers (Informal Meeting), at 7.—Discussion: L. Henshaw: The Earthing of Metal Objects other than Conductors.—S. W. Melsom: The Earthing of Electrical Circuits.

Institute of Metals (North-Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.

Institution of Electrical Engineers (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7.30.—Prof. W. M. Thornton: What is Electricity? (Faraday Lecture).

Institute of Metals (Scottish Local Section) (at 39 Elmbank Crescent, Glasgow), at 7.30.—Prof. J. H. Andrew: The Value of Research.

Surveyors' Institution, at 8.—F. G. Baxendale: The Effect on Values of Town Planning Schemes in their Various Stages.

Royal Geographical Society (at Æolian Hall), at 8.30.—Sir Arnold Wilson: A Periplus of the Persian Gulf.

Institution of the Rubber Industry (London Section) (at Engineers' Club, Coventry Street).—G. Martin: Ageing of Raw and Vulcanised Rubber.

TUESDAY, JANUARY 11.

Institution of Petroleum Technologists (at Royal Society of Arts), at 5.30.—Dr. L. Dudley Stamp: The Conditions Governing the Occurrence of Oil in Burma.

Institution of Civil Engineers, at 6.—Prof. Douglas Hay: The Economics of Power-Production and Utilisation at Collieries.

Illuminating Engineering Society (at Lighting Service Bureau, 15 Savoy Street, W.C.2), at 6.30.—W. J. Jones, H. Lingard, and T. Catten: Floodlighting.

Institute of Marine Engineers, at 6.30.—Sir Robert Hadfield: Progress in the Development and Practical Application of Heat-resisting and Non-corroding Steel.

Institution of Electrical Engineers (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—J. R. Beard and T. G. N. Haldane: The Design of City Distribution Systems and the Problems of Standardisation.

Institution of Electrical Engineers (North-Western Centre) (at Engineers' Club, Manchester), at 7.

Institution of Electrical Engineers (Scottish Centre) (at North British Station Hotel, Edinburgh), at 7.—Dr. A. Ekstrom: The Applications of Electricity to Agriculture (Lecture).

Institute of Metals (Birmingham Local Section) (at Engineers' Club, Birmingham), at 7.—H. S. Caswell: Forces set up in Strip Rolling.

Royal Photographic Society of Great Britain (Scientific and Technical Group), at 7.—L. Joseph: The Empire Model 5 Projector.

Society of Chemical Industry (Birmingham and Midland Section) (at Birmingham University), at 7.15.—C. H. Wood: A Study of the Rotatory Dispersion of Certain Derivatives of Hydroxyacids.

Society of Chemical Industry (South Wales Section) (at Technical College, Cardiff), at 7.30.—W. R. D. Jones: Magnesium and its Alloys.

Institute of Metals (North-East Coast Local Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—U. R. Evans: Some Aspects of the Corrosion of Metals.

North-East Coast Institution of Engineers and Shipbuilders (Middlesbrough Branch) (at Middlesbrough), at 7.30.—W. G. Richards: Rivets and Riveting.

Quekett Microscopical Club, at 7.30.—Dr. G. H. Rodman: Insectivorous Plants and How they Live.

Pharmaceutical Society of Great Britain, at 8.—J. H. Franklin: Notes on Preparations of the British Pharmacopoeia, 1914.

Röntgen Society (at British Institute of Radiology), at 8.15.—R. J. Reynolds: Some Experiments on the Production of Rapid Serial Skiagrams from the Screen Image by means of a Cinematograph Camera.

Institute of Chemistry (Manchester and District Section) (at Manchester).—Prof. J. B. Cohen: Air Pollution.

WEDNESDAY, JANUARY 12.

Royal Society of Arts, at 3.—Prof. C. R. Darling: The Story of a Wireless Valve (Dr. Mann Juvenile Lectures) (2).

Royal Society of Medicine (Surgery: Sub-Section of Proctology), at 5.30.—Dr. E. U. Williams and L. E. C. Norbury: Normal Variability of the Action of Pituitrin on the Contractile Power of the Caecum and Colon.—L. E. C. Norbury and C. N. Morgan: The Value of Lipiodol in Determining the Extent of Fistula-in-ano.—R. Maingot: Gummatous Colitis.—Dr. C. Dukes: Laboratory Tests for the Diagnosis of Cancer of the Rectum and Colon.—W. B. Gabriel: (a) Volvulus of the Pelvic Colon and Blind Caecostomy; (b) Skin Grafts for Fistulae.

Institution of Civil Engineers (Informal Meeting), at 6.—F. H. Livens: Dragline Excavators.

Society of Chemical Industry (Nottingham Section, jointly with Fuel Section) (at University College, Nottingham), at 7.—Dr. J. G. King: The Production of Liquid Fuels from Coal.

North-East Coast Institution of Engineers and Shipbuilders (Graduate Section) (at Bolbec Hall, Newcastle-upon-Tyne), at 7.15.—J. E. Conner: The Erection of a Rotary Portland Cement Kiln.

THURSDAY, JANUARY 13.

Royal Society, at 4.30.—F. W. R. Brambell, A. S. Parkes, and Una Fielding: Changes in the Ovary of the Mouse, following Exposure to X-Rays. Parts I. and II.—A. S. Parkes: On the Occurrence of the Oestrous Cycle after X-Ray Sterilisation. Part II. Irradiation at and before Birth.—R. M. Sargent: Recovery from Vigorous Exercise of Short Duration.—F. A. Pickworth: Basal Metabolism as determined by the Respiratory Exchange.—M. Dixon: On the Mechanism of Oxidation-Reduction Potential.—R. G. Canti and M. Donaldson: The Effect of Radium on Mitosis *in vitro*.—Dr. R. J. Ludford and W. Cramer: Secretion and the Golgi Apparatus of Islets of Langerhans.—S. Dickinson: Experiments on the Physiology and Genetics of the Smut Fungi. Hyphal Fusion.—Y. Azuma: (a) Effects of C- and K-Ions and Ultra-violet Rays upon Involuntary Muscles; (b) Effects of Ultra-violet Rays upon Skeletal Muscles.

London Mathematical Society (at Royal Astronomical Society), at 5.—P. Dienes: On Cartan's Torsion of a Tensor Space.—J. E. Littlewood: On the Class-number of the Corpus $P(\sqrt{-k})$.—L. J. Mordell: On Power Series with the Circle of Convergence as a Line of Essential Singularities.—N. Wiener: (i.) The Spectrum of an Arbitrary Function; (ii.) On a Theorem of Bochner and Hardy.

Society of Chemical Industry (Manchester Section, jointly with Institution of the Rubber Industry) (at 16 St. Mary's Parsonage, Manchester), at 7.—Dr. D. F. Twiss: Rubber Solvents.

South London Entomological and Natural History Society, at 7.

Institution of Mechanical Engineers (Glasgow Branch) (at Royal Technical College, Glasgow), at 7.30.—Prof. T. Gray: The Present Position of the Low Temperature Carbonisation of Coal.

Institute of Metals (London Local Section) (at 83 Pall Mall), at 7.30.—Dr. W. Rosenhain: Hardening.

Optical Society (at Imperial College of Science), at 7.30.

Oil and Colour Chemists' Association (at 8 St. Martin's Place, W.C.2), at 8.—H. W. D. Ward: Cadmium Colours and their Application to the Paint Industry.

Royal Society of Medicine (Neurology Section), at 8.30.—Dr. A. Turner and others: Discussion on Epilepsy.

Institution of Mechanical Engineers (Leeds Branch).—F. C. Turner: A New Load-Strain Recorder.

Institution of Mechanical Engineers (Birmingham Branch).—Informal Discussion.

FRIDAY, JANUARY 14.

Royal Astronomical Society, at 5.—Dr. J. K. Fotheringham: Some New Determinations of the Secular Accelerations of the Sun and Moon.—S. D. Tscherny: Occultations of Stars by the Moon, observed at the Astronomical Observatory, Kiew, in the Year 1926.

Malacological Society of London (at Linnean Society), at 6.

North-East Coast Institution of Engineers and Shipbuilders (at Newcastle-upon-Tyne), at 6.—Hon. Sir Charles A. Parsons and R. J. Walker: Progress in Economy of Turbine Machinery on Land and Sea.

Institute of Metals (Swansea Local Section) (at University College, Swansea), at 7.15.—Discussion on Pyrometers.

Junior Institution of Engineers, at 7.30.—R. L. Kirlew: The Thermionic Valve and its Characteristics.

Institute of Metals (Sheffield Local Section) (at Sheffield University), at 7.30.—P. Hopkinson: Gas Furnaces and their Heating.

Society of Chemical Industry (Chemical Engineering Group) (at Chemical Society), at 8.—J. A. Hall: Thermo-Electric and Resistance Pyrometry in Industry.

Philological Society (at University College), at 8.—Rev. A. Darby: Functional Grammar.

Colour Chemists' Association (Manchester Section) (at Manchester).—A. W. C. Harrison: Lake Dyestuffs and their Application.

SATURDAY, JANUARY 15.

North of England Institute of Mining and Mechanical Engineers (at Neville Hall, Newcastle-upon-Tyne), at 3.—J. S. Carson: Dry Cleaning of Coal.

PUBLIC LECTURES.

SUNDAY, JANUARY 9.

Guildhouse (Eccleston Square), at 3.30.—Dr. A. B. Cook: Animism.

THURSDAY, JANUARY 13.

King's College, at 5.30.—Prof. J. S. Huxley: The Mind: Biology.

FRIDAY, JANUARY 14.

Middlesex Hospital Medical School, at 4.—Prof. Swale Vincent: Current Views on Internal Secretion. (Succeeding Lectures on January 18, 21, and 25.)

SUNDAY, JANUARY 16.

Guildhouse (Eccleston Square), at 3.30.—G. A. de Zoysa: The Soul of Buddhism.

CONFERENCE.

JANUARY 10 AND 11.

Society for Experimental Biology (at Bedford College, Regent's Park).

(First Session) *Monday, January* 10, at 2.15 to 3.45.—G. C. Robson: Some Effects of Competition and Selection.—Prof. A. E. Boycott: Experiments on the Habitats of Planorbis and Bithinia.—R. E. Chapman: The Relation of Bicarbonates to the Photosynthesis of Water Plants.—At 3.45 to 4.30.—Demonstrations:—Prof. W. Neilson Jones: Fungal Cultures (Mycorrhizal) grown in Atmosphere (a) containing, and (b) free from, Gaseous N_2.—Dr. M. C. Rayner: Aseptic Conifer-Seedlings.—M. A. Tazelaar and Prof. J. S. Huxley: Effect of Temperature Gradients upon Early Development in the Chick.—J. Hammond: The Fate of Foetal Tissues grafted into the Uterus of the Rabbit.—At 4.30 to 6.—W. K. Slater: Aerobic and Anaerobic Metabolism of the Common Cockroach.—J. Needham: Carbohydrate Metabolism of the Developing Egg.

Television.

THE lecture delivered by Mr. J. L. Baird on Jan. 6 at the Physical and Optical Society's annual exhibition was very largely attended, and had to be repeated the same evening in order to prevent widespread disappointment. The attendance was a tribute to the intrinsic interest of the subject and to the expectations aroused by what little has become known of the lecturer's apparatus and achievements.

Mr. Baird did not add to the general knowledge by what he said and did on that occasion. The situation appears to be that he has achieved a certain success in transmitting instantaneous images divided into some thirty vertical strips, each strip showing more or less correct gradation in a vertical direction. The picture composed by the strips is therefore very coarse-grained in one direction while sufficiently graded in a direction at right angles to it. The most important point about the transmission is that it uses diffusely reflected light, and not the light transmitted, say, by a lantern slide. To the latter transmission Mr. Baird will not consent to apply the term 'television' at all, and in this we consider he is justified. The eye itself normally sees objects by diffusely reflected light, and television, to be worthy of the name and to accord with popular expectation, must do the same.

Now this proviso is a very serious obstacle to overcome. For the 'candle-power' of a brightly illuminated face is approximately unity, whereas in kinematograph projection it amounts to thousands. True television, as defined by Mr. Baird, is therefore at least a thousand times more difficult than the transmission of shadows of moving objects such as has already been achieved by several inventors, among whom Ruhmer was the first in 1907.

Mr. Baird appears to have succeeded in transmitting images of objects artificially illuminated to an extent equivalent to bright sunlight, and to have overcome the difficulties of synchronisation in transmitting and receiving within the same building. He also claims to have accomplished similar transmissions by radio over about ten miles, and to have transmitted living faces showing considerable detail. While giving him all credit for his very direct attack on a difficult problem, and for what he has demonstrably achieved, we must guard against an underestimate of the remaining difficulties. These will affect such things as synchronism, illumination, and detail.

It is comparatively easy to keep two motors running at the same speed, even at a distance. But when a difference of phase of only one degree is capable of spoiling definition, the maintenance of the correct phase becomes a formidable task. Granted that Mr. Baird transmits the equivalent of 30,000 signals per second as against the 300,000 required for satisfactory television, it is easily seen that the problem of synchronism may become sufficiently acute to bar further progress. The figure of 300,000, on which most workers on this problem are agreed, is based upon the fact that a face alone, to be recognisable, requires some 3000 graded elements. Most press portraits comprise at least 10,000 such elements; and in order to produce the illusion of continuity or motion, there must be at least sixteen transmissions of the whole picture per second.

From the information available—and it must be remembered that Mr. Baird has not disclosed the essential details of his method—it appears highly probable that little further progress need be expected along the lines chosen by him. The illumination seems to have been driven to its farthest limit, and the recent claims to have transmitted 'outlines' by infra-red rays mark no advance towards television with diffusely reflected light. The subdivision of the image by a disc of spirally staggered lenses seems incapable of extension, and the suggestion thrown out in the course of the lecture, that several photo-electric cells (and several radio-frequencies) might be used simultaneously, only serves to emphasise difficulties already known to exist.

It is to be regretted that, possibly on account of patent considerations, Mr. Baird has hitherto been unable to submit to a proper authentication of his claims by a learned society. For aught his recent audience could say, the invention might be a mere plaything, with no more resemblance to television than a toy engine has to the real thing. That is not the way to convince a sympathetic audience of experts who are expected to judge of the merits and prospects of an invention.

There are at least three pioneers in the field who seem to be on the verge of a complete solution of the television problem. Belin in France, and Alexanderson and Jenkins in America, are all approaching the problem by way of the transmission of photographs, which they accomplish in great perfection. Dr. Alexanderson, chief engineer of the Radio Corporation of America, claims to be able to transmit a complete photograph in one second, and points out that if sixteen successive photographs could be transmitted in one second, the problem of television (or, at least, of telekinematography) would be solved. He adds, however, that the difficulties, especially of synchronism, increase as the square of the speed.

It is well to remember that the earlier solutions proposed after the discovery of the light-sensitive property of selenium did not require the synchronisation of moving parts at the sending and receiving stations. But a multiplicity of wires, one for each picture element, is out of the question, and so is a multiplicity of radio-frequencies. Unless, therefore, some device such as Dr. Fournier d'Albe's acoustic resonator system can be employed for the simultaneous reception of a medley of signals, the question of synchronism, effective both in speed and phase, will arise; and when we realise that the synchronism required is that of two 'pencils' which traverse the picture completely in a sixteenth of a second, and in doing so describe several hundred lines, the mechanical difficulties may well appal us. The speed with which the stimulus can be applied at the transmitting end is great enough nowadays, for the action of a photo-electric cell shows no appreciable lag, and the use of a Braun cathode ray tube at the receiving end, first suggested, we believe, by Mr. Campbell Swinton, will solve the speed problem there.

There remains the problem of sensitiveness to illumination at the receiving end. Mr. Baird does not tell us what he uses. His results suggest a potassium photo-electric cell for ultra-violet, and either selenium or bolometer for the infra-red. If he has discovered any reagent of greatly superior power, that discovery alone would entitle him to our gratitude, and would constitute a valid claim even though all his other devices had been anticipated by others. The policy of withholding publication of an essential item does not commend itself to modern inventors. It savours too much of medieval practice, and usually defeats its own object of securing to the inventor the fruits of his invention.

It would be a source of satisfaction to us if one of our countrymen were the first to provide a practical solution of a problem of this magnitude, a solution such as the civilised world has been expecting for some years. If the solution has been reached without the scientific, engineering, and financial resources at the disposal of rival inventors, it will appeal very powerfully to our sympathy and imagination. But for the present, and on the evidence supplied, the scientific world will probably prefer to reserve its judgment.

Is Darwinism Dead?

(1) *A Companion to Mr. Wells's "Outline of History."* By Hilaire Belloc. Pp. iv + 119. (London: Sheed and Ward, 1926.) 7*s*. 6*d*. net.

(2) *Mr. Belloc Objects to "The Outline of History."* By H. G. Wells. (The Forum Series.) Pp. vii + 55 + 2 plates. (London: Watts and Co., 1926.) 1*s*. net.

(3) *Mr. Belloc still Objects to Mr. Wells's "Outline of History."* By Hilaire Belloc. Pp. x + 43. (London: Sheed and Ward, 1926.) Paper, 7*d*.; cloth, 1*s*.

QUITE a dozen years ago statements began to appear in our public press announcing that "Darwinism was dead," and so often has this assertion been repeated in more recent days that there has arisen in the public mind a fear that some sort of fatality has overtaken the reputation of the great naturalist. If by Darwinism is implied the body of fact, inference, and doctrine contained between the covers of "The Origin of Species," then assuredly Darwinism is not dead, for the revolution which that book began to work in the minds of thoughtful men sixty-seven years ago still continues its forward and unchecked progress.

The essence of Darwin's teaching is to be found in the last paragraph of the introduction he wrote for the first edition of "The Origin," and is repeated in all the later editions. There Darwin states that "I can entertain no doubt, after the most deliberate study and dispassionate judgment of which I am capable, that the view which most naturalists until recently entertained, and which I formerly entertained—namely, that each species has been independently created—is erroneous." Through Darwin's influence 'special creationists' in all the leading nations of the world were transformed into 'evolutionists.' Thus in its widest sense Darwinism implies merely the acceptance of the belief that all living things have been evolved from other and older living things. There is no book which seems so certain of a place in the permanent literature of the world as Darwin's "Origin of Species."

That Mr. H. G. Wells, trained under Huxley, should be a Darwinist in this wider sense occasions no surprise; but it was scarcely to be expected that Mr. Belloc, a devout son of the Roman Catholic Church, should be of the number. Yet, like Darwin, Mr. Belloc rejects special creation and accepts evolution; he even reproves Mr. Wells for being ignorant of the fact that "the conception of the Old Testament as an exact text-book of history and science, not a word of which must be taken as allegory or generalisation, was mainly confined to England and to her colonies. The Catholic Church never held it or could of its nature hold it" ("A Companion," p. 32). Mr. Belloc assures his readers that the theory of evolution is old, and that "the ancients and fathers of the Church" were familiar with it.

Darwinism is confined by many people to cover merely the theory enunciated in the "Descent of Man." When used in this more limited sense Darwinism cannot be considered as dead, for I do not know of any living anthropologist or student of the human body who believes that man arose by a special act of creation. Anthropologists may differ as to the kind of ape from which humanity has been evolved, and as to the geological date at which its face was turned man-wards, but on the evidence now before them, which grows in volume and in trustworthiness every year, most of our authorities share Darwin's belief that the anthropoid apes and man have sprung from a common stem. In this narrower sense Mr. Wells is a Darwinist, but so adroitly does Mr. Belloc cover his verbal tracks with a smoke-screen that it is somewhat difficult for his readers to decide whether as regards man's origin he is a fundamentalist or a Darwinist. He quotes with approbation the belief held by "St. Thomas, the great teacher of the Middle Ages," to the effect that "the creation of man was not mediate but direct." St. Thomas must, on this evidence, be classed among the fundamentalists. Mr. Belloc, however, gives his verbal assent to this narrower form of Darwinism which the fundamentalists find so objectionable; he believes in evolution; he regards the process by which man reached his present estate as open to debate; he speaks of "the moment when a true man existed at all"; he directs Mr. Wells's attention to the fact that certain tests show a close blood affinity between man and anthropoid. With such evidence before us we cannot say that Darwinism—even in this narrow sense—is dead.

Yet in justice to Mr. Belloc it should be added here that he rejects two points in Darwin's theory of man's origin. Darwin believed that man's rise from apedom was a slow and gradual process, and he hoped that the evolutionary forces which had lifted him thus high might lift him still higher. Mr. Belloc, on the other hand, prefers to believe that man's emergence was of the nature of a leap, and that he is now and will ever remain a 'fixed type.' Our scanty knowledge of fossil ape and man, and our much fuller information regarding their embryological histories, are altogether against Mr. Belloc's beliefs and in favour of Darwin's postulates, which have been rightly adopted by Mr. Wells.

There is a third and more restricted sense in which the term Darwinism is used. As an intrinsic part of the machinery which he regarded as being concerned in the evolution of living forms, Darwin introduced the principle or law of "Natural Selection," which he defined thus: "This *preservation* of favourable individual differences and variations, and the destruction of those which are injurious, I have called Natural Selection or the Survival of the Fittest" ("The Origin of Species," sixth edition, p. 63). There can be no doubt that Darwin claimed the recognition of this law and its application to the problems of evolution as his particular discovery. "Natural Selection," writes Mr. Belloc, "is the only thing that properly can be called Darwinism," and he reproves Mr. Wells for being unaware that Darwinism in this sense has been "riddled for a generation"; that it is "done for"; that it is "shaky"; that it is "nonsense"; that it is "old and exploded"; that it is "moribund"; and also that it is "quite dead."

Mr. Belloc devotes many pages to the exposition of Darwin's law of selection, and so little is the resemblance of the exposition to the original that one is forced to the conclusion that he has never read even the first chapter of "The Origin of Species." Darwinism as expounded by Mr. Belloc is certainly dead; indeed, it was never born. One does expect a historian, especially one who is ever accusing his antagonist—very unjustly—of being ignorant of recent events in the history of Darwinism, to be familiar with some of the chief happenings which followed the publication of "The Origin of Species." Mr. Belloc apparently does not know that Mr. St. George Mivart ("On the Genesis of Species," 1871), a convert to the Catholic Church, and one of the ablest anatomists of his time, formulated all the arguments which he now brings against Darwinism, and based them on an expert and first-hand knowledge of living things, such as Mr. Belloc can lay no claim to. Nor is he aware that Darwin, patient with even unscrupulous and prejudiced opponents, devoted twenty-eight pages of the sixth edition of "The Origin of Species" (1872) (pp. 176-204) to answering Mivart's criticisms. From first page to last of this sixth edition, Darwin protests against those early critics who supposed that the variations utilised by natural selection occurred 'singly' and 'accidentally'; he admits time after time that although he does not know the 'efficient cause' which brings variations into existence, yet he is certain that their appearance is regulated by many laws, "some few of which can be dimly seen," one of these being the law of 'correlated growth' whereby a whole series of structures may be modified together so as to serve more advantageously some functional purpose.

Mr. Belloc resuscitates this ancient misrepresentation of 'accidental' and 'single' variations and is thereby enabled, sitting in his armchair, unoppressed by any sense of modesty or burden of knowledge, to enumerate a dozen arguments, each ticked off after another with a triumphant emphasis, all of them demonstrating that the author of natural selection was an uncommonly stupid man and his modern critic a very clever fellow. One who presumes to criticise Darwin's "Origin of Species," especially from a mathematical point of view, should have known that Prof. Fleeming Jenkin ("The Origin of Species," sixth edition, 1872, p. 71), in 1867, had demonstrated the impossibility of a new breed or variety arising by natural selection if it had only 'accidental' variations to work upon, and that Darwin had shown this erudite professor wherein his error lay. Mr. Belloc knows nothing of this. Nor does he seem to be in touch with what is happening all around him now. It is difficult to believe that any one who sees the unceasing struggle which goes on everywhere and every year for the possession of the continents of the world and has been waged since the dawn of history, a struggle which is attended by the spread and domination of a few favoured races and the retrocession and obliteration of many less favoured races, can doubt the potency of Darwin's law of selection as a factor in the process of evolution. We may not like the way in which evolution works out its effects, but I do not think man, devise as he may, can escape from them. Certainly animals and plants in a state of Nature cannot.

In the five and fifty years which have elapsed since the sixth and last edition of "The Origin of Species" was published, we have learned much concerning how evolutionary processes work in the world of living things, much that was unknown to Darwin. We know now something of the complex laws of heredity, and of the physiological means whereby the growth of the body is regulated, so that its several parts are modified together and made to serve a functional purpose. An example mentioned by Mr. Belloc ("The Companion," p. 22) will serve to illustrate the direction in which our knowledge has improved. After citing one of Darwin's early critics to prove that "chance-made variations" could never have provided functionally useful structures, he proceeds thus: "And another biologist has well said—What is the survival value of horns without the structure to support them and muscles to use them?" Having set down this question, Mr. Belloc proceeds to answer it. "The mathematical chances," he informs his readers, "are millions and millions to one" against "the possibility of such a thing. Grant Design moulding all nature—that is, God—and this process is explicable." The impious biologist of to-day does not find it necessary to call in any divine or supernatural power to explain the multitude of changes which accompany the growth of horns in a young bull or antlers in a stag; the deity Mr. Belloc appeals to lies in the testes of these animals! The biologist knows that if a certain substance or hormone formed in the testes is withheld, none of these changes take place; if they are permitted to enter the circulation, then as the horns grow the bones and muscles of the neck increase in size and strength, the lumina of blood-vessels expand, and, what is still more wonderful, the temperament of the animal is transformed. The discovery of hormones, if it renders a direct appeal to the Almighty no longer necessary, does not in any way invalidate or lessen the efficiency of Darwin's law of natural selection; the hormone theory simply helps us to explain how variations of an adaptative nature can and do arise.

What is here written will suffice to show that Darwinism, in whatever sense we construe it, is neither an exploded creed nor a dead doctrine, and that those who assert the contrary not only sin against the light of truth, but also commit a crime by poisoning the springs from which a trusting public drinks its information.

It would be unfair to the memory of St. George Mivart were I to conclude without indicating, however briefly, the remarkable manner in which he anticipated in 1871 ("The Genesis of Species") the arguments which Mr. Belloc has brought against Darwin in 1926. Mr. Mivart began by asserting that a belief in evolution "was perfectly consistent with the strictest and most orthodox Christian theology"; Mr. Belloc echoes this statement but substitutes 'Catholic' for 'Christian.' Mr. Mivart called the "Fathers and Ancients" as witnesses for the orthodoxy of the theory of evolution, singling out St. Thomas for special mention; so does Mr. Belloc. Mr. Mivart reproved Darwin for his total ignorance of the "philosophy and teaching of the Catholic Church"; Mr. Belloc scolds Mr. Wells for the same offence. Mr. Mivart believed that structural modifications of a really useful kind were wrought by a supernatural agency; so does Mr. Belloc. Mr. Mivart believed that by a miraculous intervention man became possessed of a soul only in the last stage of his evolutionary progress; this apparently is also Mr. Belloc's belief. Darwin, as I have already mentioned, took infinite pains to answer Mr. Mivart's scientific objections, and I thought every one knew that Huxley had answered his theological arguments in a famous essay ("Mr. Darwin's Critics," 1871, Huxley's "Collected Essays," vol. 2, p. 120), but it must have escaped Mr. Belloc's attention, for he never alludes to it. Yet it is an essay which he might read with advantage, as should every one who honestly tries to reconcile Catholic beliefs with the truth of science. Even Mr. Mivart, in the end, found a reconciliation impossible. His later books were placed on the *Index Librorum Prohibitorum*, and in January 1900, when his last illness was upon him, he was excommunicated by Cardinal Vaughan because he dared to assert what his investigations into science had taught him. Such was Mr. Mivart's fate, and one wonders what would have happened to the author of "The Origin of Species" if his life had fallen in Catholic places and had his beliefs been in the keeping of Rome.

Arthur Keith.

New Quantum Theories.

Probleme der Atomdynamik. Erster Teil: *Die Struktur des Atoms*; Zweiter Teil: *Die Gittertheorie des festen Zustandes.* Dreissig Vorlesungen, gehalten im Wintersemester, 1925–26, am Massachusetts Institute of Technology. Von Prof. Max Born. Pp. xiii + 183. (Berlin: Julius Springer, 1926.) 10·50 gold marks.

CLASSICAL electrodynamic theory has had considerable success in explaining many of the phenomena of atomic physics, but there are other facts which seem to necessitate a radical departure from this theory. During the first quarter of the century many attempts were made to meet these difficulties by means of special assumptions and rules, which constituted the quantum theory. Although these methods have had remarkable success in the interpretation of a restricted region, it has long been felt that such a procedure, designedly adopted with a particular end in view, was not satisfactory and that a more general theory was required.

In 1925 Heisenberg put forward a new theory of quantum mechanics which seems likely to have far-reaching consequences, even if it does not lead to a complete solution of the problem. One of the fundamental ideas employed by Heisenberg is that only such things as are directly open to observation should enter into the mathematical formulation. He considered it advantageous to avoid every notion which cannot be connected with experiment, and so eliminated all ideas of motion within the atom. We are unable to assign to an electron a special position in space at a special instant of time, so that, so far as our observations are concerned, an electron orbit does not exist. In the mathematical statement of the new theory, developed in association with Born and Jordan, the continuous variables of the classical theory are replaced by systems of discrete quantities (matrices) which can be expressed by means of algebraic equations.

Although the theory of matrices is founded on the work of Cayley, Sylvester, and H. J. Smith, and is about seventy years old, some mathematicians and most physicists are unfamiliar with the ideas involved. As pointed out recently in these columns (NATURE, August 28, 1926, vol. 118, p. 295), the fundamental notion is by no means difficult to grasp. Cayley considered a square arrangement of numbers as constituting a matrix, realising the value of treating it as a single magnitude. Thus nine numbers put in square formation, three by three, are called a matrix of order three. For example:

$$\begin{bmatrix} 1, & 2, & 3 \\ 4, & 5, & 6 \\ 7, & 8, & 9 \end{bmatrix}$$

We may also deal with a rectangular matrix of mn numbers, arranged in m rows and n columns. The matrix is to be thought of as a *compound* unit, an assemblage of numbers arranged in order but constituting a single entity. A simple geometrical illustration is afforded by taking $[x, y]$ as specifying the position of a point in a plane. Unless $x = y$, the point $[x, y]$ is not the same as the point $[y, x]$. Such an entity, which may include a row of n numbers, is a special case of a matrix of rank one. The determinant of a matrix must be distinguished from the matrix itself, just as the area of a triangle must be distinguished from the triangle itself. Cayley gave rules for adding, subtracting, and multiplying matrices, and it is of importance in the present connexion that the product AB of two matrices A and B is not generally equal to the product BA.

The most interesting part of the volume under notice is undoubtedly that in which Prof. Max Born has described in some fifty pages the development of the new quantum mechanics. In the classical theory a particular co-ordinate may be represented by a Fourier series comprising the various components, but in the new theory the collection of all possible vibrations is to be regarded as a whole in a quadratic scheme forming an infinite matrix. If q denote such a co-ordinate matrix and p an impulse matrix, instead of assuming that the product qp is equal to the product pq, we must introduce a new postulate, namely,

$$pq - qp = h/(2\pi i),$$

where h is Planck's constant and i is the square root of -1.

P. A. M. Dirac of Cambridge has expressed the new theory in a different form by means of a specially devised quantum algebra in which the quantum variables satisfy all the ordinary laws of algebra, excluding the commutative law of multiplication. Instead a special quantum condition is postulated, involving Planck's constant and equivalent to that stated above.

Schrödinger starts from the idea suggested by de Broglie that an atomic system is not to be represented by a trajectory, that is, by a point moving through the co-ordinate space, but must be represented by a wave in this space. From this starting-point he develops a wave-theory of matter, and obtains from a variation principle a differential equation which the wave function must satisfy. This equation turns out to be closely connected with the Hamiltonian dynamical equation which specifies the system. When the general solution of this equation is known, matrices to represent the canonical variables may easily be obtained satisfying all the conditions that they have to satisfy according to Heisenberg's matrix mechanics. The mathematical equivalence of the theories is thus established, and it is shown that (in the words of Schrödinger) "the wave-mechanics and the matrix mechanics are mathematically identical." The concept of characteristic oscillations in the atom and Schrödinger's theory based upon it represent a most significant contribution to the development of the quantum theory. "From the formal mathematical point of view it includes the whole of the Heisenberg-Born-Dirac matrix theory, and gives, moreover, a simplified, practically convenient method of finding the matrices. Beyond this, it opens new avenues of thought and seems to afford our first glimpse of the true nature of the quanta" (Epstein).

The development of the new theory is taking place with great rapidity, and several applications have already proved successful; only a few of these can be mentioned here. Pauli has shown that the Balmer formula for the hydrogen spectrum can be accounted for quantitatively, as well as the influence of electric and magnetic fields on this spectrum. A theory of the Stark effect based on Schrödinger's ideas has been presented by Epstein, who considers the radiation from a hydrogen-like atom in an electric field. The calculated positions of the components of the spectral lines practically coincide with those obtained in Epstein's old theory, which gave excellent agreement with experiment. The main interest lies in the expressions for the intensities, which agree with the observed values better than those deduced by Kramers from the correspondence principle. Schrödinger himself has discussed the same problem. Brillouin has treated the subject of rotation spectra by the calculus of matrices and has found experimental verification for certain of the theoretical deductions. Dirac has discussed the extension of the theory to relativity mechanics, and in particular to the theory of Compton scattering, and obtained results which can be tested by experiment.

One test of a scientific theory is its comprehensiveness, and the wide sweep of the new quantum mechanics is shown not only in the various ways of formulating it in mathematical language, but also in the physical ideas that may be associated with it. It is probable that the views of the quantum suggested by E. T. Whittaker and by the present writer, in which its magnetic aspects are emphasised, may be simply related to the new theory. In a recent paper Whittaker has described a simple light quantum in which a disembodied magnetic molecule, travelling with the speed of light, forms a singularity on the wave front and confers upon it the desired quantum properties. It may be suggested that such a quantum is related to a quantum magnetic tube on one hand, and to Schrodinger's wave mechanics on the other.

In discussing the relation between the quantum theory and the classical laws, Dirac remarks that the new theory "suggests that it is not the equations of classical mechanics that are in any way at fault, but that the mathematical operations by which physical results are deduced from them require modification. *All* the information supplied by the classical theory can thus be made use of in the new theory."

H. S. Allen.

Our Bookshelf.

A Text-Book of Organic Chemistry: Historical, Structural and Economic. By Prof. John Read. (Bell's Natural Science Series.) Pp. xii + 680. (London: G. Bell and Sons, Ltd., 1926.) 12*s.* 6*d.* net.

Owing to the fact that systematic organic chemistry is but rarely taught in our public and secondary schools, elementary text-books on the subject are far less numerous than books on the inorganic branch. We have, it is true, a few excellent introductions to organic chemistry, but there is still room for a few more, especially if, like the present work, they are written in an agreeable style, are accurate, do not intimidate the beginner with a vast mass of unrelated facts, and, above all, show traces of original treatment.

Prof. Read departs from precedent by prefacing the subject with a fifty-page sketch of the development of chemistry as a whole, and although one might urge that much of this matter is not strictly relevant, the innovation is nevertheless welcome, not only because it is well done, but also because this phase of chemistry needs more emphasis than it has been given in the past. Another useful feature of the book is the insertion of references to industry and economics, which, as the author states, undoubtedly stimulate and maintain the interest of students. In this connexion, however, it is important that the statements and figures should be as up-to-date as possible, and that the period of time to which they relate should be precisely stated.

In the book under notice one would expect to, but does not, find adequate references to such recent and important matters as the large-scale manufacture of urea, cellulose-nitrate varnishes, acetic acid from cellulose by anaerobic fermentation, insulin, and the 'berginisation' of coal. Further, wholesale prices are far more important than those charged by the retailer, and when we read (p. 314) that "commercial oxalic acid costs about 10*d.* per lb., and the purified substance about 1*s.* 6*d.* retail," we can but marvel at the patience of the small consumer, because for a long time past the market price of the 98-100 per cent. commodity has been less than 6*d.* a pound, and now it is less than 4*d.*

Prof. Read and his publishers deserve our thanks for producing a thoroughly sound and interesting work.

The Modern Soap and Detergent Industry, including Glycerol Manufacture. By Dr. Geoffrey Martin. In 3 vols. Vol. 3: *The Manufacture of Glycerol.* (Containing the Index to the Complete Work.) Pp. xi + 78 + 36 + 13 + 20 + 8 + 41 + 57. (London: Crosby Lockwood and Son, 1926.) 30*s.* net.

The working up of the by-product, glycerol, of the soap and stearin candle industry is of such economic importance that the author has felt justified in allotting this entire volume to the subject of glycerol. In attempting to prepare a complete treatise (as the present volume claims to be) on any branch of chemical industry, great difficulties confront the writer. Many books of such a type, while apparently satisfactory to the technological student, are often to the works' chemist of less value and perhaps incomplete. This is mainly due to the unwillingness of manufacturers (very often for good reasons) to divulge details of processes which may be of indirect help to rival firms.

In the work under review it may justly be claimed that the author has collected together a great many practical details of modern glycerol plants and processes, especially in the sections dealing with the working of evaporators and stills. In fact, in no similar single publication, at least in English, can such a mine of useful information be obtained. The author has been extremely fortunate in having secured the valuable aid of various industrial firms, including still-makers, in the compilation of his data. In addition, as in the previous two volumes of this series, references are given to practically all the important related patents, including even those at present of no industrial significance, on the subject of glycerol production and application. A useful section on polymerised glycerol and glycerol substitutes is also included. In the final section the commercial valuation and analysis of glycerol and the various specifications for products of different grades are treated in a very satisfactory manner.

An exhaustive index for the three volumes is also included in the present work, with cross references. The complete work forms an indispensable reference treatise on the technical literature of the soap and delegent industry.

J. REILLY.

Practical Ultra-Violet Light Therapy: a Handbook for the Use of Medical Practitioners. By T. Clyde McKenzie and A. A. King. Pp. 108 + 14 plates. (London: Ernest Benn, Ltd., 1926.) 6*s*. net.

THIS handbook is for the use of medical practitioners; it contains a foreword by Sir John Robertson, the Medical Officer of Health for Birmingham, who is keenly alive to the part which this form of therapy is playing and is likely to play in the near future.

Doctors have now to know something of the technique of the sources of ultra-violet radiation, of the effects to which the rays give rise, and of the diseases which are favourably influenced thereby. The book under notice, in a restricted sense, provides this information; the authors write practically only upon their own experiences, and these appear to be restricted to the use of the mercury vapour lamp. They give an excellent account of these lamps, of the way in which they should be used, and of the diseases for which their use is warranted. We can understand, however, that many medical practitioners will want to know something about the open arcs which are largely used in many of the big light clinics.

Dosage in this form of therapy is still rather primitive; the 'normal dose' according to the authors may be taken to be "that which will produce in the patients' most sensitive skin surface the faintest perceptible erythema."

No doubt in time there will be established a physical unit of ultra-violet radiation which will be of service in medicine, and it is to be hoped that the interval will not be so prolonged as has been the case in X-ray therapy.

The American Annual of Photography, 1927. Vol. 41. Edited by Frank R. Fraprie and E. J. Wall. Pp. 238 + 54. (Boston, Mass.: American Photographic Publishing Co.; London: B. T. Batsford, Ltd., 1926.) 1.50 dollars.

THIS well-known annual appears this year in a new form with a much larger page, which gives more scope for the considerable number of half-tone reproductions with which it is embellished. The text also is improved, for the articles are fewer, longer, and of more interest; and the developer formulæ are set out in a more businesslike and concise form than we have been accustomed to, a strictly comparative table for each type of developer being given on the basis of 1000 parts of water in every case. Mr. E. J. Wall gives a practical digest of the year's work in photography, which is fuller than such summaries generally are, including working formulæ in almost all cases, and with occasional valuable comments. Mr. Wall also contributes a historical article on the desensitising of plates, written with his usual thoroughness. Among the other articles of special scientific value is one by Dr. Wightman on "Photographic Sensitivity and the Latent Image," and one by Messrs. J. I. Crabtree and J. F. Ross on "The Recovery of Silver from Exhausted Fixing Baths." All these contributions mentioned have full references to the original sources of information appended to them, forming valuable bibliographies of the subjects.

An Almanack for the Year of Our Lord 1927: containing an Account of the Astronomical and other Phenomena, and a Vast Amount of Information respecting the Government, Finances, Population, Commerce and General Statistics of the various Nations of the World. By Joseph Whitaker. Complete edition. Pp. lvi + 896 + lvii-clxxxiii. 6*s*. net. Abridged edition. Pp. xlviii + 240 + lvii-clxxxv. Paper, 1*s*. 6*d*. net. (London: J. Whitaker and Sons, Ltd., 1927.)

THE new edition of 'Whitaker' has undergone some rearrangement and contains several new features, but its familiar appearance and convenient form remain unchanged. Among the new features are fifty-seven short articles dealing with questions of the day so varied as betting, Kent coalfields, polar flights, and war debts; a summary of science and invention, art, music, and the drama during the year, and details of meteorological conditions in June, July, August, and September for half a century. The statistical information about all states of the world is given as usual. The 'abridged edition' now takes the place of the 'popular edition,' which is discontinued. It contains not a selection but an abridgment of the contents of the larger volume, and is a marvel of value at the price.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Beginning of Agriculture.

AT the present moment there is a widespread misunderstanding of the nature of the evidence that is now available to suggest how, when, and where the practice of tilling the soil began. It is not my intention to traverse the whole field so fully explored in 1921 by Prof. Thomas Cherry in his address on "The Discovery of Agriculture," delivered at a meeting of the Australian Association for the Advancement of Science; but new information is now available that confirms the accuracy of his statement, which should dispel the doubts and difficulties that have arisen.

I suppose most people would be prepared to admit that the invention of agriculture was the beginning of civilisation. It involved a really settled society and the assurance of a food supply. Hence it created the two conditions without which there could have been no real development of arts and crafts and the customs of an organised form of society. But for many years there has been a sharp conflict of opinion as to how and where this momentous event took place.

In 1901 it was my good fortune to become associated with Profs. George A. Reisner and Albert M. Lythgoe in the most thorough study of an early pre-dynastic site (Naga-ed-Der in Upper Egypt) that has ever been made. In the course of examining the well-preserved bodies found in this cemetery, I recovered from the alimentary canals of a large number of bodies the food which these people had consumed about sixty centuries ago. This material I sent for examination to Dr. Fritz Netolitzky, the professor of pharmacology in the University of Czernowitz, who is the leading authority on the subject. Prof. Netolitzky published an account of the results in the *Zeitschrift fur Untersuchung der Nahrungs- und Genussmittel* (1911, Bd. 21, p. 607) and *Die Umschau* (1911, pp. 45 and 95). At the same time he sent me a letter summarising his results, which I quoted in the little book, "The Ancient Egyptians," I was then engaged in writing.

The statement that barley was the staple article of diet in Egypt from the earliest pre-dynastic period has passed without any notice whatever during the last fifteen years, excepting the use made of it by Prof. Thomas Cherry. In recent discussions that have been taking place at the meetings of the British Association, the Royal Anthropological Institute and elsewhere, as to the beginning of agriculture in Egypt, I am told that no reference of any sort has been made to these fundamental facts, the neglect of which must necessarily sterilise any real investigation of this most important issue.

Dr. M. Gompertz has directed my attention to a fact (which I had not realised until then) that in his memoirs published in 1911, Prof. Netolitzky has not made any unequivocal statement on the barley question. In fact, the only place in which the issue is explicitly mentioned is his memoir in *Die Umschau* (1911), which is almost identical with the private letter its author sent to me in the same year. But there is an important difference between the letter and the published statement. In the latter the statement is made that in almost every sample of the early pre-dynastic Egyptians' food, which I sent to Dr. Netolitzky, there is evidence of the husks of "the barley-wheat-type" (Gersten-Weizentypus), whereas in Dr. Netolitzky's private letter the corresponding sentence ran "in almost every sample there was evidence of the husks of barley." The difference between these two statements was so vital that I wrote to Prof. Netolitzky and asked him for further information. In a letter dated Nov. 25, 1926, he says:

"Barley is the chief cereal found in the Naga-ed-Der specimens. I am of the opinion that wheat was not eaten at that time, for we certainly should have found it if it was present in the specimens, because we can detect the much softer fragments of the husks of barley where the much harder and more characteristic husks of wheat are completely lacking. We can therefore assume that the Naga-ed-Der people did not use wheat; at any rate it is absent in the numerous specimens that you sent me. Some years ago the late Dr. Bruijning, of the Agricultural Experimental Station at Wageningen, wrote to me to say that he had come to the conclusion that wheat first came into Egypt at the beginning of the dynastic period. Schulz ('Die Geschichte der kultivierten Pflanzen,' 1, 1913) expresses the conclusion that barley was the first cereal used in the Nile Valley."

Prof. Netolitzky has also been kind enough to send me a paper by Frau Hedwig Gherasim ("Neue Kennzeichen der Getreidespeizen und Beitrage zur Bestimmung prähistorischer Pflanzenfunde," *Pharmaz. Monatsheften*, 1921) which contains the following statements. She says that while Prof. Netolitzky was convinced barley was the chief cereal used by the pre-dynastic Egyptians, at the time she began her research he had not definitely excluded the possibility—his letter to me in 1911 shows it to have been only a possibility—that wheat might also have been used, because in the material from Naga-ed-Der there was a number of husks of indefinite type (his barley-wheat-type). The solution of this problem he postponed for further investigation and then entrusted the task to Frau Gherasim, who says that she has now examined Prof. Netolitzky's material and has been unable to find a single case in which the diagnosis of wheat can be established, whereas there is ample evidence that barley was present in most of the specimens she examined. She says this discovery is of extraordinary interest and importance, for it definitely establishes the fact that the pre-dynastic people did not eat wheat. The number of specimens is so great that such an assertion can be made with complete confidence. The earliest example of *Triticum dicoccum* appears to be that found by Borchardt in the foundation at the west end of the offering-granary in the temple of King Sahure of the fifth dynasty. Dr. Cherry and others have pointed out, however, that it may have been in use in earlier dynastic times.

The question of the cultivation of barley in Egypt is not merely a matter of local interest, but also involves the much wider problem of the origin of civilisation itself. During recent years there have been repeated discussions as to the relative antiquity of Sumerian and Egyptian civilisation. Prof. Breasted now tells us that this question has been definitely settled once for all. In his book, "The Conquest of Civilisation," which was published a few weeks ago, he makes this statement (p. ix): "Perhaps the most far-reaching consequences among newly-discovered sources are the new cuneiform tablets with [Sumerian] dynastic lists at last determining the maximum age of the earliest Babylonian written documents. They are at most a little earlier than 3000 B.C. Thus it is now a finally established fact that civilisation first arose in Egypt, followed a few centuries later by Babylonia." The opinion he expresses agrees with that of most of the experts of Great Britain, Europe and America who have first-hand knowledge of the material found within recent years in Mesopotamia.

It is now generally admitted that the first dynasty of Ur can be dated at 2900 B.C., and that the most remote age that can be assigned to it is 3100 B.C. Painted pottery has been found in Susa [Elam] which may be, and probably is, earlier than the first dynasty of Ur; but this has been equated with the pottery distinguished as Susa II. This follows Susa I., which it is generally estimated corresponds to the middle pre-dynastic period in Egypt. In other words, in Egypt the whole duration of the early pre-dynastic period is definitely anterior to any evidences of civilisation that have been found in Asia or in fact anywhere in the world. If, then, the early pre-dynastic evidence reveals the presence of cereals and suggests that agriculture was then being practised, we have positive evidence of the most significant kind that civilisation began in Egypt. We know also that people in Egypt at this time, many centuries before the metal copper was known, were using the copper ore malachite, which there is every reason for believing was obtained from the Wady Alaqi in Nubia. These and scores of other facts to which I have been constantly directing attention, in season and out of season, during the last fifteen years, establish on a firm foundation the certainty that civilisation, not merely agriculture and the working of metals, but also the invention of all the essential arts and crafts, customs and beliefs that go to the making of early civilisation, were first invented in the Nile Valley.

The fact that the alimentary canals of all those earliest Egyptians contained barley is surely certain evidence that barley was growing in Egypt at that time. Whether it was indigenous or not we have of course no direct evidence to prove, because every foot of land that can be cultivated in the Nile Valley has been turned over countless millions of times during the last sixty centuries by an unbroken series of *fellahin*. But the fact that wild barley is found in the north-east corner of Africa, both on the Mediterranean littoral and in the regions to the south and east of Egypt, suggests that it was also growing in the Nile Valley when men first made their way into that strip of land.

The only alternative is to assume that the earliest Egyptians brought barley into the country with them. I need scarcely say that this is a mere speculation, in support of which there is no evidence of any sort, not even a suggestion of its likelihood. The conclusion that is forced upon us is that the earliest settlers in the Nile Valley found barley growing there in a wild state and made use of this natural food supply. Living under such ideal conditions, the population, in course of time, increased to such an extent that the natural supply was inadequate to support them. Then it can be assumed men imitated the natural processes which they had watched year by year for unknown centuries, and by extending the area of irrigation instantly devised the art of irrigation and the invention of agriculture. This is the only reasonable interpretation of a vast mass of evidence.

Wireless Communication and Terrestrial Magnetism.

THE letters which have recently appeared in NATURE on the relationships of wireless reception and terrestrial magnetism suggest that a few remarks from the point of view of a magnetician may not be superfluous. First, on an historical point, it should be remembered that estimates of the altitude of a stratum of high electrical conductivity were made long before the times of wireless communication. Cavendish (*Scientific Papers*, vol. 2, p. 233) in 1790 obtained on strictly scientific grounds an estimate of from 84 to 114 km. for the altitude of an auroral arc. Prof. Stormer's methods of high precision have supplied numerous results for the lower level of aurora, which have long been well known. The levels he has found show variations with similar limits to those recently obtained by Appleton and Barnett (*Roy. Soc. Proc.*, A, vol. 113, p. 450). Auroral observations, of course, are not possible by day, and we may hope to learn much from wireless which it might be difficult or impossible to derive from auroral observations.

Again, the continual existence of high electrical conductivity in the upper atmosphere was first advanced as an hypothesis neither by Heaviside nor by Kennelly, but by Balfour Stewart. His statement will be found in §§ 121 and 134 of his article on "Terrestrial Magnetism" in the ninth edition (epoch *circa* 1882) of the "Encyclopædia Britannica." Stormer has shown that on special occasions aurora may extend to heights exceeding 600 km. Thus the term 'layer' applied to the space of high conductivity may not be a very appropriate one. But if any name is to be associated with a 'conducting layer' in the upper atmosphere, it should surely be neither Heaviside's nor Kennelly's, but Balfour Stewart's.

The arguments for the existence of the 'conducting layer' on the side of terrestrial magnetism, even leaving aurora out of account, are by no means wholly theoretical. The strongest argument, in the opinion of the writer, is derived from the observed large universal increase of the diurnal variation of the magnetic elements as we pass from sunspot minimum to sunspot maximum. No such universal relationship has been observed in any meteorological or other element at the earth's surface, or in the lower atmosphere, except in the case of electrical earth currents, and these are generally believed, through their association with aurora, to be a direct consequence of the electrical currents overhead.

It is this argument that has led practically all, if not all magneticians, to accept the upper atmosphere as the seat of electrical currents to which the regular diurnal variation of the magnetic elements is due. It is important to notice that it is the regular diurnal variation that has been observed to hold a parallel course to sunspot frequency. Speaking generally, years of few sunspots are less disturbed magnetically than years of many spots, but a year of many spots may not be a highly disturbed year. Thus 1893, though a year of sunspot maximum, was much quieter than either 1892 or 1894.

All the magnetic elements show largely increased diurnal ranges in years of many sunspots. In Britain the increase seems larger for H (horizontal force) than for D (declination). In H an increase of 100 in Wolf's sunspot frequency has corresponded to a rise of about 100 per cent. in the range of the mean diurnal inequality for the year. The effect varies with the season of the year, the percentage rise in the range at Kew being roughly twice as great at midwinter as at midsummer. With increasing sunspot frequency, the tendency seems to be for the increase of amplitude to be larger in the 24-hour Fourier wave than in the waves of shorter period. This implies in the average day a reduction in the difference between day and night.

There is an important difference in Europe between quiet and disturbed days. On quiet days the magnetic changes are much larger in the day than in the night hours; but during large disturbance the night hours are the most active. Large disturbance in Europe is much more common between 4 P.M. and 4 A.M. than between 4 A.M. and 4 P.M.; it is rare near 10 A.M. This difference between night and day is not, however, universal all over the earth. In the Antarctic, from 1911 to 1913, disturbance was much more in evidence during the day than the night hours. The distribution of magnetic disturbance throughout the 24 hours in high northern latitudes still apparently awaits investigation.

Another result of interest is that the regular diurnal variation, whether in years of many or of few sunspots, tends to be larger on disturbed than on quiet days. This seems to imply that in addition to local irregularities in the conductivity of the 'conducting layer,' due presumably to the irregular distribution of the sources of ionisation, there is during magnetic disturbance a decided increase in the average conductivity. This phenomenon is comparatively trifling in southern England, but increases in prominence as we go north. If we may judge from what happened in the Antarctic in 1911 to 1913, it is exceedingly prominent in high magnetic latitudes, at least in years of few sunspots. At Cape Denison, the base station of the Australasian Antarctic Expedition, the range of the regular diurnal variation of H in the midwinter months for an average international magnetic character of 1·05—which implies only very moderate disturbance—was nearly six times the range from the international quiet days. Magnetic disturbance in these high latitudes is much larger and more persistent than in central Europe. This suggests that the natural place to study the relationships between wireless and magnetic phenomena is not the south of England but the north of Scotland, or still more northern regions. There are now magnetic observatories at Lerwick, Sodankyla (Finland), Matochkin Shar (Novaya Zemblya), Godhavn (Western Greenland), Meanook (Canada), and Sitka (Alaska). Wireless observations at two or more of these stations ought to provide in a short time a lot of interesting material.

The Symmetrical Top in Wave Mechanics.

IN a recent issue of NATURE (Dec. 4, 1926, p. 805) there appeared a letter of Messrs. R. de L. Kronig and I. I. Rabi, in which they gave, on the basis of the new wave mechanics of Schrodinger, an expression for the energy of a symmetrical rotator, *i.e.* a rigid polyatomic molecule having two equal moments of inertia.

A like result has also been obtained by F. Reiche (*Zeit. f. Phys.*, 39, 444, 1926) using the wave mechanics. Furthermore, under the assumption that the molecule possesses a permanent electric moment along the direction of its figure axis, Reiche derived to first order approximation the addition to the energy expression caused by placing the molecule in an external electric field. Independently of Reiche, also using the wave mechanics, we have carried the calculation to the second order of approximation and have thus been able to compute the dielectric constant. We find for the total energy $W^*_{j,m,n}$ of the molecule in the presence of an electric field of strength F

$$W^*_{j,m,n} = W_{j,n} - \mu F\frac{mn}{j(j+1)} + \frac{(\mu F)^2}{h^2/8\pi^2 A}4(\Phi_{j,m,n} - \Phi_{j+1,m,n}),$$

where $W_{j,n}$ is the energy of the molecule without electric field, as already given by D. M. Dennison (*Phys. Rev.*, 28, 318, 1926) using the matrix mechanics. μ represents the permanent dipole-moment, A the moment of inertia about an axis perpendicular to the figure axis, and j, m, and n three quantum numbers. The first of these may take all positive integral values not including zero, while the others may take both positive and negative integral values including zero, subject to the restriction that the absolute value of each shall not exceed the value of j. The function $\Phi_{j,m,n}$ is a numerical factor depending only upon the quantum numbers:

$$\Phi_{j,m,n} = \frac{(j^2 - m^2)(j - n^2)}{(2j-1)(2j)^2(2j+1)},$$

$\Phi_{j+1,m,n}$ is the same expression, where only $j+1$ is substituted in place of j.

From the energy expression given above, the dielectric constant of a perfect gas is found to have the following value at high temperatures:

$$1 + \frac{4\pi}{3}\frac{N\mu^2}{KT},$$

where T is the absolute temperature, N the number of molecules per unit volume, and k the Boltzmann constant. This result is in complete agreement with the value of the dielectric constant of such molecules already found by Kronig (*Proc. U.S. Nat. Acad. Sci.*, 12, 608, 1926) using the matrix mechanics, and it means that at high temperatures the dielectric constant obeys the law of Langevin-Debye. We have found that at usual temperatures the departure from this law cannot exceed a few per cent.

It may be remarked that the second term in the energy expression given above predicts the existence of a Stark effect of the first order in the band spectra of symmetrical molecules, whereas for diatomic molecules an effect only of the second order is to be expected. The separation of the lines in the Stark effect of the first order for symmetrical molecules depends upon the magnitude of the dipole-moment and the field strength, but *not* upon the moments of inertia of the molecule. The intensity of the lines, on the other hand, is dependent upon the moments of inertia. The separation of the lines in the Stark effect of the band spectra of polyatomic molecules, which a simple calculation shows to be of a sufficient magnitude to be measured experimentally, thus provides a means of finding the dipole strength of such molecules. One finds $\Delta\lambda/\lambda = 22 \times 10^{-6}$ with $F = 50{,}000$ volts/cm. and $\mu = 1 \times 10^{-18}$ C.G.S. units.

A detailed paper covering the work outlined here will appear shortly by one of us in the *Physikalische Zeitschrift*.

The Homologues of the Adrenal or Suprarenal Bodies in Teleostean Fishes.

THE homologues of the adrenal or suprarenal bodies in teleostean fishes have long been the subject of discussion. In 1884, Weldon (*Quart. Jour. Micr. Sci.*, 1884, 24, 171-182) thought that the adrenals were frequently absent from this group, and that the lymphoid head-kidney took their place in these cases. This theory was refuted by one of us in 1896 (Swale Vincent, *Proc. Birm. Nat. Hist. and Phil. Soc.*, 10, Part 1, 1896). In the meantime it was commonly assumed that the pale, spherical bodies, near the caudal end of the kidney, on its ventral or dorsal surface, were the homologues of the adrenal bodies in higher vertebrates (Swale Vincent, *Trans. Zool. Soc. Lond.*, 14, Part 3, 1897). The corpuscles of Stannius, as these bodies were named, appeared, in fact, to have roughly the structure of the inter-renal of the elasmobranch, and the cortex of the adrenal of higher vertebrates.

In 1908, E. Giacomini (*R. Acad. delle Scienze dell' Instituto di Bologna*, 24 maggio, 1908) put forward another claimant for the position of teleostean adrenal cortex, namely, groups of glandular-looking cells in the lymphoid head-kidney, and stretched out along the blood vessels in this region. Since that time it has been customary to refer to the anterior and posterior cortical adrenals in these fishes.

The work of Giacomini seemed to minimise the importance of extirpation experiments carried out upon the corpuscles of Stannius, in which experiments eels were found to live indefinitely after extirpation of these bodies (Swale Vincent, *Proc. Roy. Soc. Lond.*, 62, 1897).

We have recently had occasion to study the microscopic structure of the corpuscles of Stannius and the 'anterior adrenal bodies' of Giacomini. Using approved modern histological methods, we are satisfied that we have to deal not with two isolated portions of the same structure or organ, but with two totally separate and distinct glands, having in all probability different functions. This is indicated by a striking difference in the general appearance of the sections and is confirmed by measurements of the various elements. There are also obvious microchemical differences in the two structures.

In examining the detailed cytology, we have received much assistance from Dr. C. da Fano, of King's College, London, who has made for us preparations to show the Golgi apparatus. He agrees with us that the two structures bear very little resemblance to each other and that the Golgi apparatus has a different arrangement in the two cases.

We are inclined to believe that it is the anterior adrenal body in the head-kidney which ought to be considered the homologue of the adrenal cortex; and, if this is correct, this body should be styled simply the adrenal cortical body. If this is so, what are we to say of the corpuscles of Stannius? Here is a perfectly definite circumscribed organ for which we have to find a place, both morphological and physiological. One is tempted to place it, provisionally, in the group of epithelial organs, in which are included the anterior pituitary, corpus luteum, the parathyroids, islets of Langerhans, etc. It has occurred to us that it may, in fact, be an insulin-producing tissue, and if sufficient material can be collected, it is our intention to test this. We hope to publish a full account of this work at a later date.

Scientific Achievement and Aptitude.

The excellent editorial in Nature of Nov. 13 suggests a few comments. Several years ago, Lady Gregory came to the University of Colorado and lectured on the Irish drama. She insisted on the importance of each country or region fostering its own dramatic art, and cultivating dramatic expression among its citizens. Under such conditions, she urged, not only is there a quickening of the general intelligence, but also genius finds its appropriate setting and chance for appreciation. Surely the same argument may be used with reference to science. It is not possible to determine the native ability of various nations from such statistics as are cited by Dr. Slosson. Very much depends on popular recognition, and even the discovery of new chemical elements is largely controlled by opportunity. Although the genius is an asset of incalculable value, he is only of value to communities intelligent enough to profit by his labours. In 1914, 105,681 infants under one year died in Great Britain. In 1924 the number was only 65,259. In the same period the deaths per thousand were cut down from 23·9 to 19·3. This was not done through the brilliant inspiration of some genius, but by the incessant labours of thousands of relatively or absolutely obscure persons using the knowledge communicated by scientific men of all grades of distinction.

My own interest in natural history was greatly stimulated by J. W. Taylor and W. D. Roebuck, who were preparing a "Monograph of the Land and Freshwater Molluscs of the British Isles." Their methods were in direct contrast to those of some monographers. We not rarely hear that so-and-so is monographing the ——. All specimens must be sent to him. No one else should have anything to say on the subject. By the time the great work appears, interest in its topic has so long been dead, that it is received with due reverence but little real joy. There are, of course, some fields of science which are necessarily cultivated in this manner. Only a few men of unusual training and powers, provided with unusual and costly apparatus, can do anything with them. The 'man in the street' is absolutely out of it, except as a possible contributor of funds. But in other fields this is not the case. Taylor and Roebuck, from the beginning, did everything to interest young conchologists in the possibilities of doing things, of making discoveries. The result was a great deal of enthusiasm and the accumulation of an enormous mass of data which eventually went into the monograph. It is lamentable to have to record that this beautifully illustrated and minutely detailed work has ceased publication, because the cost of printing is too high. As a contribution to national culture it would abundantly pay the country to continue the printing at the public expense.

The moral seems to be, that whether we desire material benefits or increased happiness, bread or song, it is of the utmost importance to cultivate scientific interest among the people at large. This interest should not simply take the form of open-mouthed astonishment at the works of the learned, but should be inspired by the hope and expectation of personal accomplishment, and the sense of having part in a great undertaking.

Behaviour of Silicic Acid Gel during the Drying-up Process.

In the *Proceedings of the Indian Association for the Cultivation of Science* for June 1926, K. Krishnamurti in a short note describes the formation of fibres of potassium chloride when crystallised from silicic acid gel. This note was apparently written as the result of an observation made in May 1924.

On October 18, 1924, we communicated to the *Journal of Physical Chemistry* a paper, "Some

Observations on the Preparation and Properties of Silicic Acid Gel," which was published in March 1925. In this paper we describe the fibre-like crystals of sodium chloride obtained when crystallised from silicic acid gel. This publication seems to have perturbed Mr. Krishnamurti, since in his note of June 1926 he emphasises the fact that his *observation* was made prior to the date of the communication of our paper.

However, we decided to make no comment on Mr. Krishnamurti's remarks, knowing that our observations would receive such consideration from scientists as they deserved.

In a letter published in Nature of December 11, 1926, Mr. Krishnamurti accuses us of having overlooked his contribution in our more recent publications. In particular, he refers to our paper published in *Proc. Roy. Soc.*, A, vol. 112, p. 468, 1926, on "Change of Crystal Structure of some Salts when Crystallised from Silicic Acid Gel: The Structure of Silicic Acid Gel." Mr. Krishnamurti's remarks are incorrect, even assuming that his note merited mention in our published work. If he will take the trouble to refer to our paper in the *Proc. Roy. Soc.*, he will find that the paper was communicated on May 17, 1926, hence it would be impossible for us to include in that paper a reference to a paper which was not published until June 1926.

Mr. Krishnamurti will also be interested to learn that we gave a summary of our last paper before the Chemistry Section of the British Association at Southampton in September 1925.

For Mr. Krishnamurti's information only we beg to state that our first observation of the formation of needle-like crystals of sodium chloride from silicic acid gel was in November 1923, but of course this was not publicly recorded until we had completed our investigation of the problem in hand.

[Discussions of priority of observation or publication are of limited interest and tend to become purely questions of personal differences of opinion. We much prefer, therefore, not to give further space to such matters as are referred to in the above letter.—Ed. Nature.]

A Source for Resonance Radiation.

While engaged in some experiments on mercury resonance radiation at Johns Hopkins University last spring, I became convinced that a less erratic and, if possible, more intense source than the usual water-cooled quartz arc was almost a necessity for some kinds of work. A high-voltage discharge seemed likely to be much steadier than a low-voltage arc, and an obvious way of cutting down self-reversal due to normal mercury vapour was to use a gas for the discharge, with mercury present at a relatively low pressure, secondary processes keeping the mercury atoms largely in excited states. Experimental work was interrupted, however, and it was only recently that an opportunity arose for testing such a source in comparison with a regular quartz mercury arc.

A quartz tube 7 mm. in diameter and 20 cm. long, provided with tungsten electrodes and containing argon at a pressure of about 6 mm. and mercury vapour at a pressure corresponding to 50° C. was excited by a small wireless transformer. The voltage across the tube was 1500. Used as a source, this tube produced an intensity of resonance of λ2536 about half as great as that produced by a water-cooled quartz arc of the usual type. The arc was used without a magnetic field, but was cooled during the exposures at such a rate that it was extinguished in about a minute, thus producing the maximum intensity of resonance. The argon tube required no cooling or magnetic field and seemed perfectly steady and capable of indefinite operation without attention. I am grateful to Messrs. Foote and Mohler for apparatus used in these tests.

It is probable that the intensity of the 'gas-discharge' source can be greatly increased. The pressures given above are approximately optimum values for the particular tube and excitation used, but the possibilities of obtaining greater intensity by using greater power input (the tube was comparatively cool), end-on illumination, other gases, perhaps an arc instead of a high-voltage discharge, etc., have not been tested. The device recommends itself as it stands, however, by its great convenience of operation and the ease with which it can be constructed in the laboratory. It appears likely that this source would be advantageous for resonance measurements when using a photo-electric cell instead of photographic plates.

It is quite possible that such a gas-discharge tube has been used elsewhere as a source for mercury resonance. Dorgelo has used a similar discharge, although for a different purpose. The tube is also quite similar to those used by Wood and others for sodium, but its advantages over the much-used water-cooled mercury arc have seemed worthy of this notice.

Collisions of the Second Kind between Ions and Atoms or Molecules.

Some experiments dealing with collisions of the second kind between ions and atoms or molecules have been performed independently and simultaneously in two different laboratories—one at Princeton University and one at the University of California. Through correspondence the different investigators have learned of each other's results and have decided to present jointly, in this letter, a preliminary report of this phenomenon, which heretofore has been unknown. In both researches, the apparatus used are essentially those described in the positive ray experiments by Smyth (*Proc. Roy. Soc.* and *Phys. Rev.*) and by Hogness and Lunn (*Phys. Rev.*). One set of experiments is the preliminary stage of a complete study of the whole phenomenon; the other is incidental to work on the positive ray analysis of nitric oxide.

Mixtures of two gases, in equal amounts, have been ionised by electron impact, the impact electrons having velocities well above the ionisation potential of either of the gases. In each case the relative amounts of the two ions formed were determined as a function of the pressure of the gas mixture in the apparatus, and it was found that the relative amount of that ion corresponding to the higher ionisation potential decreased regularly with increase of pressure. The phenomenon can be explained only by collisions between ions and atoms or molecules, in which the ions rob the colliding atoms or molecules of one of their electrons, the process taking place with evolution of energy.

The results thus far obtained are given by the following equations:

$$\begin{aligned} He^+ + Ne &= Ne^+ + He, \\ Ne^+ + A &= A^+ + Ne. \\ A^+ + NO &= NO^+ + A, \\ He^+ + NO &= NO^+ + He. \end{aligned}$$

The ionisation potentials of He, Ne, A, and NO are 24·5, 21·5, 15·4, and 9 volts respectively.

With diminishing pressure the above reactions take place to smaller extent and, in each case, the ratio of the relative amounts of the two ions, extrapolated to zero pressure, is that due only to electron impact ionisation. This extrapolated ratio gives the relative probabilities of ionisation of the different ions. The results thus obtained are in agreement with those of K. T. Compton and C. C. Van Voorhis (*Phys. Rev.*, 27, 730, 1926).

Photo-electric Polarimetry.

WITH reference to the letter from Dr. J. Kenyon published in NATURE of February 27, 1926 (vol. 117, p. 304), which I have only just happened to see, I should like to add the following.

H. von Halban and K. Siedentopf in July 1922 applied for a German patent for methods of photo-electric polarimetry. The patent was granted as No. 386,537 and taken up by the optical works of R. Winkel, Göttingen.

The processes described in their specification were critically examined by K. Mayrhofer. This investigation was finished by July 1924 and the results were embodied in a Würzburg dissertation in 1924.

The best results were obtained with an arrangement in which the variations of luminosity of the source (mercury lamp) were compensated by using two cells.[1]

The light emerging from a monochromator was split up by a quartz plate. The transmitted ray passed through a polarimeter specially built by Messrs. Winkel on a potassium photo-electric cell with argon filling, while the reflected ray fell direct on a similar cell. The voltages on the two cells were so distributed that the photo-electric currents balanced, as shown by a single-fibre electrometer. Thereupon similar vessels with the solution to be tested were introduced into the two beams. This cancelled the loss of light by absorption and left only the change due to polarisation, which was then compensated by rotation of the nicol.

With this method measurements were made on the mercury lines down to 2536 Å.U. The readings could be reproduced with an accuracy of 0·01° in the strong ultra-violet lines, and rather less accurately in the feeble lines.

The same method can of course also be used for absorption measurements, and results were obtained for potassium chromate which agree well with those obtained by other methods.[2]

If, however, only absorption measurements are required, it will be found better to use the two-cell method of von Halban and Siedentopf (*ibid.*), since the polarimeter, with its many reflecting surfaces, introduces much loss of light.

A detailed publication of Mayrhofer's measurements will appear shortly in the *Zeitschrift fur physikalische Chemie*.

The Double Normal State of the Arc Spectrum of Fluorine.

IN NATURE of December 4, p. 804, Mr. de Bruin suggests that Millikan's complex hot spark lines of fluorine, at λλ607,657, are to be attributed to FI. The components of these lines exhibit intervals which, within the rather wide range of experimental error in this difficult region, are equal to the intervals Δ^4P_{12}, $\Delta^2P'_{12}$, and Δ^2P_{12} occurring among the red lines of FI, but it does not appear possible to form the groups into complete multiplets in such a way as to give the equalities undoubted significance. The assignment of these groups to FI is very hazardous, in view of the fact that they have been produced only under the extreme conditions of the hot spark. It may be recalled that Millikan at first assigned them to FVII.

In a recent paper (*Proc. Roy. Soc.*, A, 113, p. 323) I have given evidence that the ionisation potential of the neutral fluorine atom is approximately 17 volts. The ultra-violet groups in question correspond to excitation potentials of about 20 volts and 19 volts respectively. It would appear, therefore, that if Mr. de Bruin's assignment is correct, the groups must require the simultaneous excitation of two or more electrons for their production. This is unlikely, in view of the satisfactory correlation of the terms involved with those predicted by the Heisenberg-Hund theory on the supposition that only one 2_2 electron is excited. It therefore seems probable that the extreme ultra-violet lines are emitted by a fluorine atom which has been ionised one or more times.

Rate of Work done by Athletes.

IN an article by Dr. J. S. Haldane and Dr. Y. Henderson in NATURE of August 28, p. 309, are references to the rate at which a man in good physical training can do work. For example, in a mile and a quarter rowing race the rate was 0·57 horse-power; and again, Douglas and Haldane, for short bursts of climbing, reached a rate of 0·9 horse-power.

It occurred to us that these rates might be exceeded by a runner raising his own weight against gravity when dashing up a flight of stairs with a running start. These experiments were easily carried out with a stop watch, and the rates obtained by a young man aged twenty-five years were, for a height of stairs mounting to 7½ feet, 13 feet, and 125 feet vertically, 1·87, 1·70, and 0·87 horse-power. The last experiment is a severe tax on the heart, and is not one to be recommended.

An interesting question is the efficiency per pound weight of the athlete. This resolves itself into the simple question of the vertical velocity, and in such experiments a man would probably have to take second place to a dog, a cat, or a sparrow. What is the most efficient living creature?

Total Solar Eclipses in the British Isles.

By Dr. W. J. S. Lockyer.

On June 29 of this year the sun will be totally eclipsed over a belt of northern England. Unfortunately, this event takes place very early in the morning, the total phase beginning at about 5h 24m G.M.T. or 6h 24m B.S.T., so that the sun will be only about 12° above the north-eastern horizon. Nevertheless, even under these rather unfavourable conditions, every one who has never seen the sun totally covered by the moon should make an effort on June 29 to be somewhere on that belt of country from which to see the striking spectacle of a total solar eclipse.

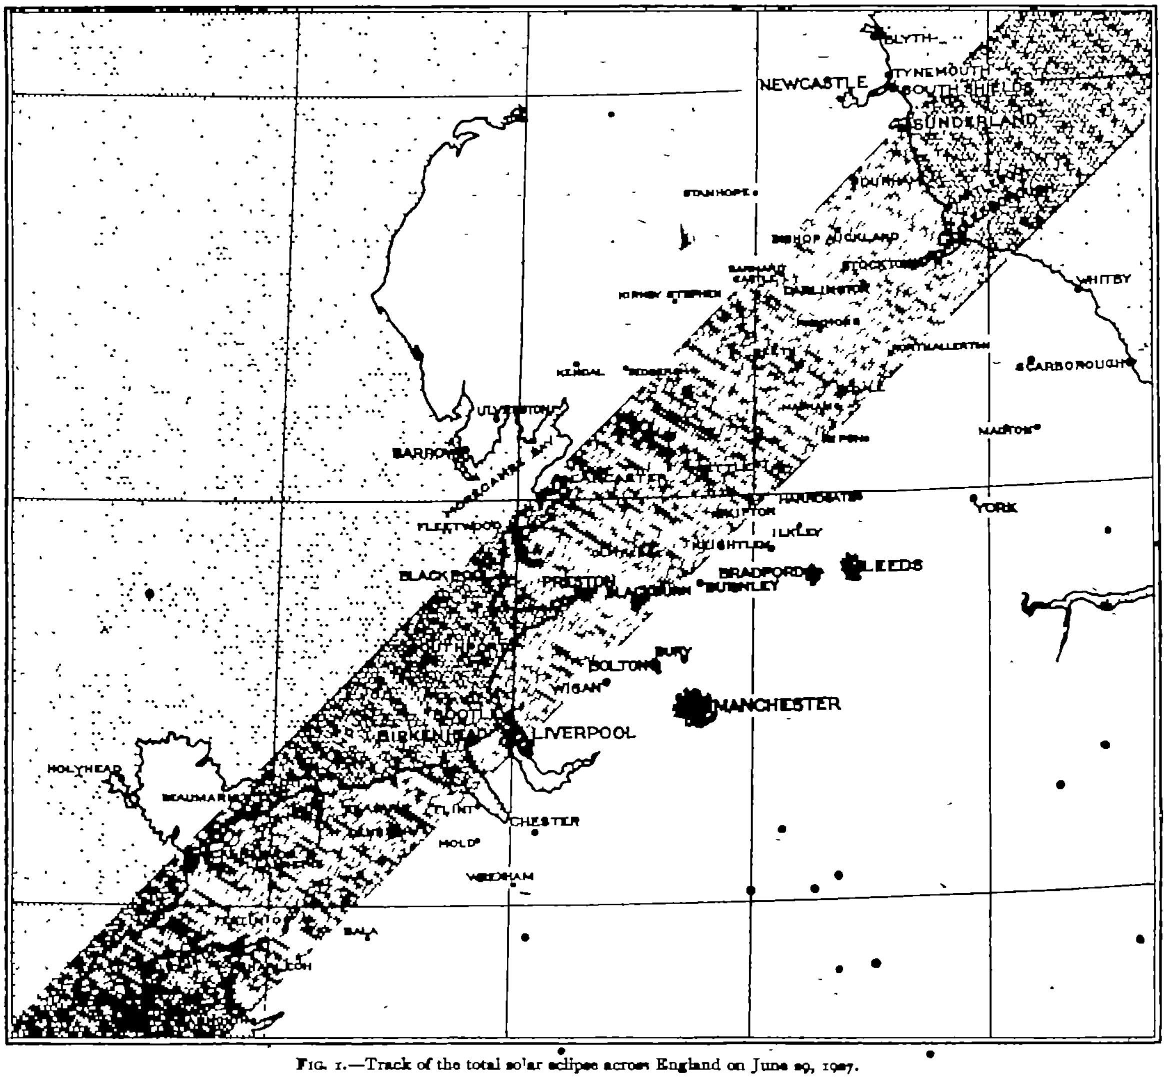

Fig. 1.—Track of the total solar eclipse across England on June 29, 1927.

An approximate position of the path of the moon's shadow is indicated on the portion of a map of England illustrated in Fig. 1. The breadth of the belt is about 30 miles, and the nearer the observer is to the centre of this belt the longer is the duration of totality. The central line of totality strikes the west coast of Britain near Criccieth, in Carnarvon, passes over Southport and nearly over Preston. It then sweeps over the north part of Yorkshire, and passes over Settle and Richmond, finally leaving the coast in the southern portion of the county of Durham, and passing over Darlington and Hartlepool and a little to the north of Stockton. The duration of totality is about 24 seconds, but is a little shorter than this on the west coast and a little longer on the east coast. Large towns just inside the border line of this belt are Carnarvon, Liverpool, Burnley, Skipton, Lancaster, and Durham.

So far, reference has been only made to that part of the track of the moon's shadow which first crosses England after commencing in the eastern Atlantic. Its later course is north-easterly, extending over Norway, Sweden, Lapland, and skirting the west coast of Novaya Zemblya. It then strikes easterly over the Arctic Ocean and north-westerly over north-eastern Siberia, terminating its course in the north-western portion of the Pacific Ocean.

The most satisfactory places for large, well-equipped expeditions will undoubtedly be in Sweden and northern Norway, for there the sun will be well up in the sky and the eclipse of longer duration.

Formerly there were many problems that could be investigated only during a total eclipse of the sun. The rapid advancement of solar physics during the last half-century has so considerably reduced these in number that the importance of observing eclipses from this point of view is much reduced. Thus, it is now known that the corona is a solar and not a lunar appendage; that the prominences can be seen whenever the sun is visible without having to wait for an eclipse to observe them; the study of the spectrum of the chromosphere in the photographic region is not now so important as it was; Einstein's theory of the bending of light by solar influence has been proved and requires no further repetition.

The main problems still to be studied are the exact times of the four contacts for the problem of the moon's motion; the red end of the chromospheric spectrum; the spectrum of the corona, best studied when the sun is in its greatest state of activity; and, finally, the form of the corona. Even the last mentioned is nearing solution, because it is now ascertained that coronal matter is closely associated with prominence matter, and that the positions of the prominences as regards solar latitude are intimately tied up to the positions of the coronal streamers. Thus it is well known that the

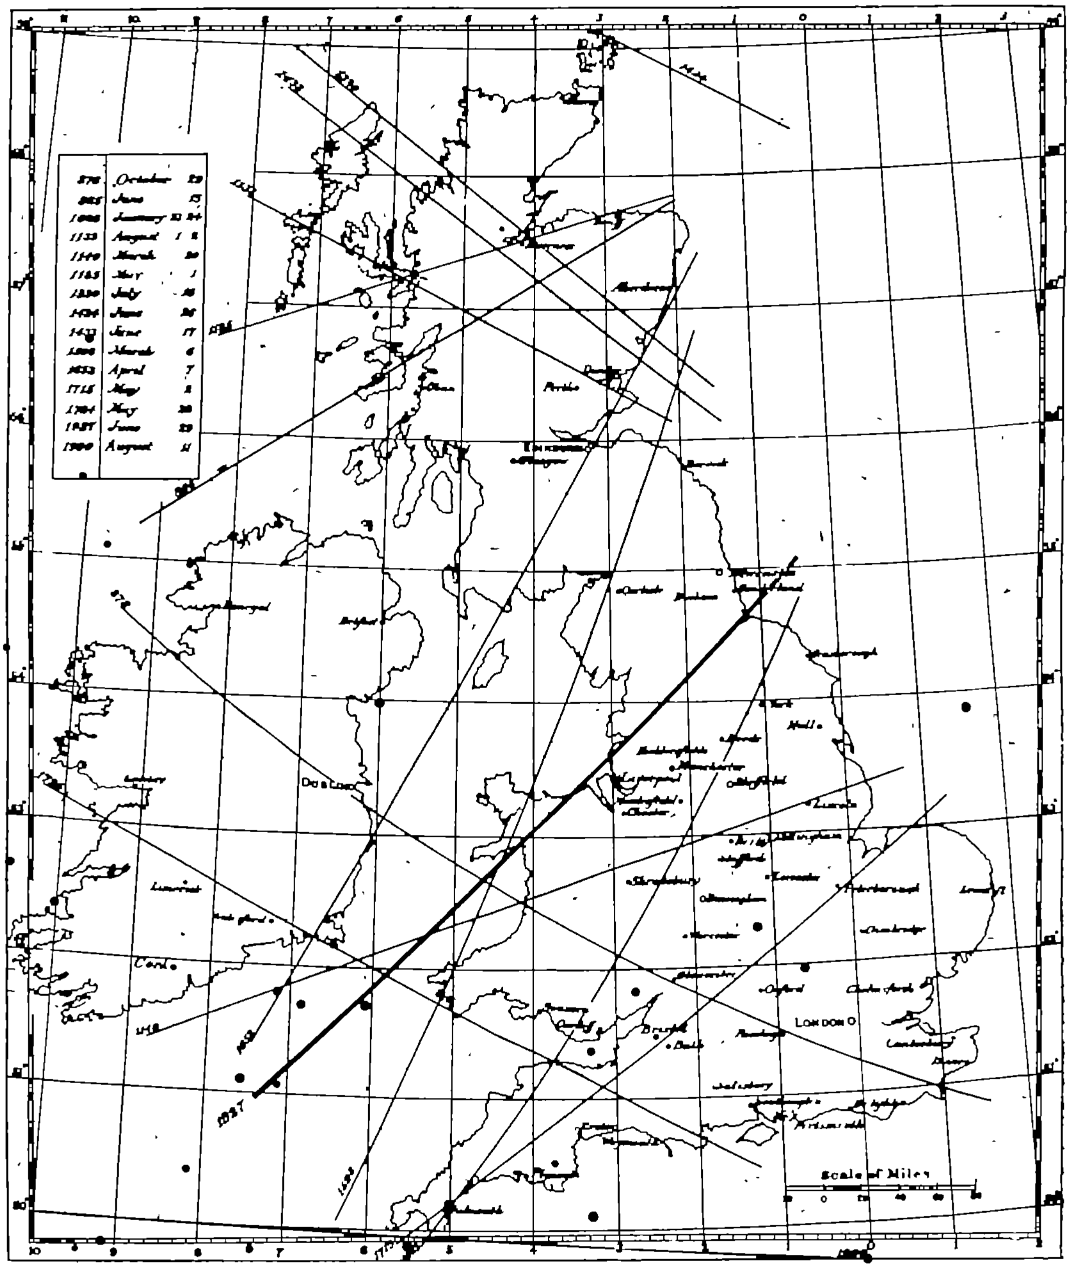

FIG. 2.—Map of total solar eclipses visible in Great Britain and Ireland from 878 to 1999.

form of the corona assumes one of three main types, a polar or maximum form, an intermediate or square form, and a minimum or wind-vane form. The polar form only occurs when the prominences are active near the solar poles. Next year the prominences will be near the poles, so that the type of corona is expected to be of the ' polar ' or ' maximum ' type.

In connexion with the passing of the moon's shadow over England this year, it is of interest not only to refer to other total eclipses visible in the British Isles, but also to inquire when the next one will take place. A very interesting map was published in the *Monthly Notices of the Royal Astronomical Society* in 1885 in a paper by Mr. J. Maguire, entitled "Total Solar Eclipses Visible in the British Isles, 878–1724." This map is here reproduced (Fig. 2) in a simplified form, to show the centres of the tracks only: those for 1927 and 1999 have also been inserted.

The eclipses here represented commence with the year A.D. 878, and show that thirteen total solar eclipses have occurred in the British Isles since and including that date. The last to take place was that of 1724, so that no total eclipse of the sun has occurred in these islands for the last 203 years.

Accounts of early English eclipses, whether total or partial, are generally alluded to in the "Saxon Chronicle." Thus, the very first record of one occurring in Great Britain, namely, the partial eclipse of A.D. 538, is referred to in the "Chronicle" in the following words: "In this year the sun was eclipsed fourteen days before the Calends of March from early morning till nine."

For the year A.D. 733, the "Chronicle" relates that "in this year Ethelbald captured Somerton; and the Sun was Eclipsed, and all the Sun's disk was like a black shield; and Acca was drawn from his bishopric." According to the Rev. S. J. Johnson, this eclipse was not total but annular, and is the first record of such an eclipse in England.

Omitting references to later eclipses, and coming to that of A.D. 1140, this was total over England, the centre of the track just skirting the south of Ireland, and leaving the east coast of England about the town of Lincoln. About this eclipse the "Chronicle" states: "In the Lent the sun and the day darkened about the noontide of the day, when the men were eating; and they lighted candles to eat by. That was the thirteenth day before the Calends of April. Men were very much struck with the wonder." This eclipse was evidently a very dark one, for William of Malmesbury stated that "while persons were sitting at their meals, the darkness became so great that they feared the ancient chaos was about to return, and upon going out immediately, they perceived several stars about the Sun."

The Scottish eclipse of 1652, when the central line passed near Wicklow in Ireland, and left the east coast of Scotland at Peterhead, is of interest because it was the first eclipse observed in the British Isles after the telescope had first been used in the eclipse of 1612.

The total eclipse of 1715 was of special importance to British observers, because London came well into the shadow belt, the central line passing over Falmouth in Cornwall and leaving the east coast at King's Lynn in Norfolk. Another interesting feature was the fact that the celebrated astronomer Halley received orders from the Royal Society "to provide for the observation to be made at their house in Crane Street," and for this purpose he published a special map showing the whole shadow path over England. With regard to this map he wrote:

> "Having found, by comparing what had been formerly observed of Solar Eclipses, that the whole Shadow would fall upon *England*, I thought it a very proper opportunity to get the Dimentions of the Shade ascertained by observation; and accordingly I caused a small Map of *England*, describing the Track and Bounds thereof, to be dispersed all over the Kingdom, with a Request to the Curious to observe what they could about it, but more especially to note the Time of Continuance of Total Darkness, as requiring no other Instrument than a *Pendulum Clock*, and as being determinable with the Utmost Exactness by reason of the momentaneous Occultation and Emersion of the luminous Edge of the Sun, whose least Part makes Day. Nor did this fail of the desired Effect, for the Heavens having proved generally favourable, we have received from so many Places so good Accounts, that they fully answer all our Expectations, and are sufficient to establish several of the Elements of the *Calculus* of Eclipses, so as for the future we may more securely rely on the Predictions: Though it must be granted, that in this our Astronomy has lost no Credit."

Halley seems to have collected quite a large party at Crane Court, for he says that

> "There were with us a great many members of the Society. and the Right Honourable the *Earl of Abingdon*, and the Lord Chief Justice *Parker* were of the number: . . . There were also present Gentlemen of other Nations, and among them Monsieur *le Chevalier de Louville* and Mr. *Monmort*, both of them Members of the *Royal Academy of Sciences at Paris*."

Even in 1715 the occurrence of a total eclipse was quite likely to alarm the people, for Halley thought it advisable to warn the public as he states below:

> "The like Eclipse having not for many ages been seen in the Southern Parts of Great Britain, I thought it not improper to give the Publick an account thereof, that the sudden darkness, wherein the Stars will be visible about the Sun, may give no surprize to the People, who would, if unadvertized, be apt to look upon it as ominous, and to interpret it as portending evill to our Sovereign Lord King George and his Government, which God preserve."

The observation of this eclipse was favoured with fine weather, and Halley describes how the

> "face and colour of the sky began to change from a perfect serene azure blue to a more dusky livid colour, intermixed with a tinge of purple, and grew darker and darker till the total immersion of the Sun."

The well-known phenomena of 'Baily's beads,' first named such after the observation in Scotland of Mr. Baily at the annular eclipse of the sun of May 15, 1836, was distinctly noted by Halley in this eclipse of 1715, for he stated that "about two Minutes before the Total Immersion, the remaining Part of the Sun was reduced to a very fine Horn, whose Extremities seemed to lose their Acuteness and to become round like Stars."

During the total obscuration, which lasted 3^{m} 22^{s}, the planets Jupiter, Mercury, and Venus, as well as the stars Capella and Aldebaran, were seen with the naked eye, and "there appeared a luminous ring around the moon as on the occasion of the eclipse of 1706." This luminous ring or corona was regarded at that time as a structureless aureole appertaining to the moon and not, as we know it now, the upper regions of the solar atmosphere, only visible during total eclipses.

Those who have observed total eclipses are familiar with the feelings of weirdness of the occasion, the chilly and damp nature of the air, and the behaviour of animal life, and many who will observe their first total eclipse this year will also be able to corroborate the following account of the 1715 eclipse given by Halley:

> "I forbear to mention the *Chill* and *Damp* with which the Darkness of the Eclipse was attended, of which most *Spectators* were sensible and equally *Judges*: or the Concern that appear'd in all Sorts of *Animals, Birds, Beasts*, and *Fishes* upon the Extinction of the Sun, since ourselves could not behold it without some sense of Horror."

The eclipse of 1715 was followed by that of 1724, which took place in the month of May, and was the last to be observed as total in Great Britain. The track of totality passed over the southern portion of Ireland and the south-west portion of England, London being situated just outside the northern boundary. This eclipse was well observed, and Halley again played an important part in connexion with it.

After June 29, 1927, the next total eclipse that will be of special interest to observers in the British Isles is that which will occur in 1999 on August 11 (see Fig. 2). The central portion of the track just skirts the extreme southern coast of Cornwall, so that totality will only be visible to those stationed in the extreme south-west of England. At that remote epoch it is difficult to forecast what the work of the astronomer will be. It is safe to say, however, that the problems now studied during total solar eclipses will all be solved, but it is almost as certain that new problems will have arisen which will necessitate possibly still greater attention being paid to the study of the sun under eclipse conditions. Even if there were no scientific reasons for observing total solar eclipses, they must still attract close attention by reason of the remarkable solar phenomena which then become visible and the weird and awe-inspiring feelings which are aroused by the spectacle.

Spinning Electrons.

By R. H. FOWLER, F.R.S.

THE past fourteen or fifteen months have seen some striking advances and simplifications in theoretical physics. The trench warfare of the preceding three years, which consolidated the ground and marked out slowly the key positions for the new attack, is past. That attack has been launched with almost complete success. The first fury of the advance is perhaps now over. At least it is now possible to survey our older difficulties afresh, to find in many cases that they are no longer formidable. It therefore seems the right moment, and perhaps of general interest, to try to indicate the parts played in this advance by the more striking of the ideas associated with it—in this article the spinning electron. In a later article it may be possible to discuss similarly the other primary conception—the new mechanics, and particularly Schrödinger's equation. Without any assertion of finality in the description of electronic interactions by its means, the importance of the spinning model of the electron can scarcely be over-estimated. Yet the spinning electron has been so lost in the far wider ideas embodied in the new mechanics that it is as yet scarcely appreciated at its full value. It is convenient therefore to devote this article to it alone.

Without prejudice to the difficult prior questions of internal structure, we may regard the electron merely as a singularity in space—the source of the external field by which it is known to us. Until recently this singularity has always been assumed to be the simplest possible, with the external field of an electrostatic point charge acting radially and symmetrically in all directions. The first serious suggestion that the electron should be treated as a more complicated singularity appears to have been made by A. Compton (*Jour. Franklin Inst.*, 192, 145, 1921). In connexion with a survey of gyromagnetic, diamagnetic and ferromagnetic phenomena he suggested that the singularity might be such as to give rise to the magnetic field of a magnetic doublet besides the usual electrostatic field. Structurally, such an electron must have an axis of symmetry—the doublet axis—and it is natural to think of its magnetism as arising from a spin of its charge about this axis, which will therefore also be its axis of mechanical angular momentum. The fields above mentioned are of course the fields of the electron relative to a set of axes in which its centre is at rest. Relative to other axes they must be derived by the transformation of Lorentz.

We will now show in turn how the use of this more complicated model of the electron resolves the remarkable set of paradoxes in which atomic theory had involved itself by the spring of 1925, owing, as we now see, to the use of an inadequate mechanical model. The most clear-cut of these depends on the statistical conception of weight, so that its appeal is perhaps not so direct as that of some of the others. We know, by a purely enumerative study of atomic spectra and their structure in magnetic fields, the total number of states which must be associated with any one spectral term of an atom or ion. This total is the statistical weight of the term. We know further that spectral terms can be grouped into sets, each characterised by a maximum multiplicity R. If R is one, all the terms are single. If R is two (for example, for sodium), the S terms of the set are single and the rest double, and so on. The weight, as counted above, for an S term of a spectrum of maximum multiplicity R is always R. Now the normal state of any once ionised atom is the core of the atom during the various stages of capture of the next electron. The weight of the core is therefore R, indicating that it can split under perturbation into just R different states. The new electron then comes in, and describes its possible orbits about the core in an approximately central field of force. If the electron is a point charge there seems no escape whatever from the conclusion that the total number of states of total quantum number n must be asymptotically equal to n^2 for large n, and the total number of states of core and orbital electron Rn^2. The actual number found is $2Rn^2$ for all n in all cases. No form of the quantum theory yet propounded offers a rational escape from this paradox, *unless the electron has a structure*. The difficulty of avoiding the enumerative difficulty in any other way is exceedingly grave, though it lies rather deep and is not readily appreciated. Its gravity comes from the fact that it depends solely on the number of degrees of freedom and an asymptotic approximation at great distances to the law of the inverse square for the force between the electron and the ion, which can scarcely be called in question. If, however, the electron spins and can set its axis at just two inclinations relative to the plane of its orbit, the paradox disappears.

The second paradox was the better-known anomalous Zeeman effect. By Larmor's theorem the action of a magnetic field on any stationary state of any atom should split the state into a number of states equidistantly spaced, and this spacing should be the same whatever the original state. As a result every spectral line should split into a certain triplet called the normal Lorentz triplet. In fact, such triplets are rare, being found only for lines of singlet systems. The general more complicated splitting structures found can be formally described by assigning to each state a splitting factor g depending on the type of the state. Larmor's theorem asserts that $g=1$ always. It has been known for some time that the anomaly could be formally explained if the magnetic moment of the atom arose from two sources, of which one was the orbital angular momentum contemplated by Larmor's theorem. The other source must then be such that its ratio (magnetic moment)/(mechanical moment) is twice the ratio of the magnetic and mechanical moments arising from orbital motion. The spin of the electron provides just this source of supply, and exact examination shows that it provides a complete explanation.

The third paradox was the so-called relativity-doublet formula, for the separations found between pairs of X-ray or pairs of optical terms. Familiar cases are the separations of the $K\alpha_1$, $K\alpha_2$ X-ray doublet and the D-lines of sodium. The separations which obey the theoretical formula vary in absolute magnitude by a factor of 10^7, which is accounted for by its salient feature, a factor approximately Z^4, where Z is the atomic number. It was thought most unlikely that any other type of perturbation could supply just this vital factor, but it is impossible rationally to accept this origin. For if we do, the sodium doublet, for example, must be interpreted as due to the difference of energy, owing to the variation of mass with velocity, of orbits of azimuthal quantum numbers one and two and the same total quantum number in an inverse square field. At the same time the much greater difference between the *pair* of P orbits and the S orbit, for example, must be interpreted as a difference of energy due to differences of penetration into a non-inverse-square field again by orbits with different azimuthal quantum numbers one and two. The pair of P orbits must for one purpose have the same and for another different azimuthal quantum numbers! If, however, the electron has a magnetic moment, there will be a secular perturbation of its axis by the magnetic field which arises from the linear velocity of the electron in the field of the nucleus, and a corresponding secular perturbation of the plane of the orbit. We can at once show from this that the energy of a single orbit in a central field of force splits up into a set of energies the differences of which vary as Z^4 as required. Finally, if the ratio (magnetic moment/mechanical momentum) required for the Zeeman effect is assigned to the electron, and the calculation of the perturbation exactly carried through, we obtain the proper quantitative formula for the doublet separation. This now enters as the difference of energy between orbits, otherwise the same, for which the momentum of the electron $h/2\pi$ has its two different orientations with respect to the plane of its orbit.

It was of course this success which finally established the value of the spinning electron. The idea and its development in this connexion we owe to Goudsmit and Uhlenbeck. Bichowsky and Urey obtained independently most of the same results. The finally correct numerical form of the separation formula is due to Thomas.

Two further paradoxes may be mentioned. One was that it appeared from a study of the behaviour of spectra in strong magnetic fields (Paschen-Back effect) that four quantum numbers must be used to specify the orbit of an electron. If the electron is a structureless point, with therefore three degrees of freedom, three quantum numbers are the maximum allowed by any form of quantum theory yet proposed. But if the electron has a rigid structure, it has in all six degrees of freedom. If further, as is assumed, its axes of spin and angular momentum always coincide, its orbits can be fully described by five quantum numbers, of which one, defining the magnitude of the spin, is invariable and may be ignored.

The last paradox to be mentioned is the following. In spite of numerous attempts to produce a coplanar model of the helium atom, most physicists have remained convinced that the normal state of helium must correspond to orbits filling three-dimensional space round the nucleus. But there was then the grave difficulty that a diamagnetic atom could not result. Two equal moment-vectors cannot have a zero resultant unless they are oppositely directed and the orbits coplanar. But when the moments of the electrons are added, there are four vectors to combine and the difficulty disappears.

We see then how the spinning electron has brought order out of chaos in the broad outlines of atomic theory. Its necessity and its successes are qualitatively independent of the new mechanics. Without in any way underrating the importance of the new mechanics, it is fair to say that its first effect on the determination of atomic weights and energy values is confined to small adjustments, such as replacing an integer n by $n+\frac{1}{2}$, or n^2 by $n^2-\frac{1}{4}$. (It is not until we come to the extremely important resonance theory of Heisenberg that the new mechanics brings in primary effects on the energy values.) These refinements are of course necessary for the correct theory. But the broader difficulties we have been discussing depend solely on the spinning electron for their solution, and order reigns once again.

It would not be right in a description of the recent work on the spinning electron to pass over in silence a remarkable essay by L. V. King.[1] This embodies an attempt to break right away from the recent trend of atomic physics, to find in *h* a characteristic constant of a spinning electron, and to develop thereby an almost classical theory of matter and radiation which hopes to avoid all the old classical difficulties without appeal to external postulates such as those of the quantum theory. The exposition given hitherto is, it must be confessed, difficult to follow, and it is difficult to believe that the author has really proved all that he states. A fuller exposition would clear up such points. There is much to admire in gallant excursions such as this; whether they turn out right or wrong it is by such excursions that physics lives.

---

Obituary.

Mr. T. S. P. Strangeways.

THOMAS STRANGEWAYS PIGG STRANGEWAYS, who died prematurely after a month's illness at Cambridge on Dec. 23, was a retiring man of strong character who had done remarkable work in pathology and tissue culture. Born on Dec. 28, 1866, his original name was Pigg, which he changed to Strangeways on his marriage. Educated medically at St. Bartholomew's Hospital, where he obtained the Matthews Duncan gold medal (1895) and took the qualification of the Conjoint Examining Board (M.R.C.S., L.R.C.P.) in 1896, he was assistant curator of the Museum and came under the inspiring influence of the late A. A. Kanthack, with whom he early collaborated in the *Journal of Pathology and Bacteriology* and in the *Transactions of the Pathological Society of London*. He accompanied that distinguished pathologist when in 1897 he left St. Bartholomew's to become professor of pathology at Cambridge.

Strangeways was appointed demonstrator of pathology in 1897, and held this office under Sir German Sims Woodhead until after the War, so that many generations of Cambridge medical students hold his teaching in grateful remembrance. His handbook on "Clinical Pathology and Practical Morbid Histology" passed into a seventh edition in 1912. He was made an honorary M.A. of the University in 1900, and in 1905 became the first Huddersfield lecturer on special pathology, this endowment being provided by a fund collected by Sims Woodhead from friends residing in or connected with Huddersfield.

Up to this time, Strangeways' life and work had been those of an ordinary university demonstrator, but he now struck out a new line in the intensive study of special diseases of a chronic nature and, under the ægis of a strong committee, energetically and successfully organised a special hospital for the investigation of selected cases. This research hospital, at first in a small private house, was in 1912 properly accommodated in a specially built hospital which was opened on May 24 by the late Sir Robert Brown of Preston, a generous benefactor to the institution. Already four thousand cases of rheumatoid arthritis had been exhaustively investigated pathologically, clinically, and therapeutically; researches had been made into gout, purin metabolism, and the opsonic index by Strangeways and the keen collaborators he gathered together; the results of these researches were collected in the five well-illustrated volumes of the "Bulletin of the Committee for the Study of Special Diseases." The museum of the research hospital contained 2000 arthritic joints dissected and mounted by him.

For the first three years of the War the work was suspended, as the hospital was given over to wounded officers, but continuation of the work showed that at least seven pathological forms of rheumatoid arthritis can be recognised clinically. In 1923 the wards of the hospital were again closed for a time in order to concentrate on tissue culture *in vivo* and *in vitro*, with the object of studying cancer patients in the hospital. The extremely valuable results thus obtained appear in Strangeways' papers in the *Proceedings of the Royal Society*, and his books, "Tissue Culture in Relation to Growth and Differentiation" (1924) and "The Technique of Tissue Culture *in Vitro*" (1924). His observations on the effect of X-rays and radium on tissue cells growing *in vitro* deserve special attention. Thus beginning as a pathologist, he became a biologist, as was eloquently shown in "G. P. B.'s" tribute in the *Times* of Dec. 30.

Strangeways had the power of communicating his enthusiasm to others, and was a lovable collaborator. He bore his infirmity of deafness with admirable patience, and has left a memory behind him which his friends will ever regret. Unfortunately his family are left with very scanty means, and five of his seven children are boys whose education is not completed, the youngest being eight and the eldest twenty-one years of age.

H. R.

Prof. R. W. Phillips.

The late Prof. Reginald W. Phillips, who had been head of the Department of Botany at the University College, Bangor, for nearly forty years, was born at Talgarth, Breconshire, on Oct. 15, 1854. He took the two years' course of training at the Bangor Normal College, where he was certificated as elementary school teacher in the December of 1874. During 1875 he was headmaster of a school in Ferndale, but soon left to become lecturer at his old college, where he remained until 1881. He then became a scholar of St. John's, Cambridge, at the same time studying for the London B.Sc. In 1884 he was appointed head of the Department of Biology at the newly established Bangor College, and a little later he became professor of botany. As the University of Wales had not then come into existence, the college confined itself to the preparation of students for London degrees; and as there was no efficient system of secondary education the devoted band of teachers at the college had, for years, to hold matriculation classes, in addition to the ordinary degree courses.

Prof. Phillips was a keen observer, and an excellent field naturalist. He became an enthusiastic student of the marine algæ; especially of the Florideæ. He supplied the article on "Algæ" to the eleventh edition of the "Encyclopædia Britannica"; and during the years 1895–1897, contributed to the *Annals of Botany* a series of valuable studies of "The Development of the Cystocarp in the Rhodomelaceæ," "The Rhodymeniales," etc.

In 1898 Phillips obtained his London D.Sc., and at this time became so engrossed in problems of Welsh education, acting as chairman of the governors of the Bangor secondary schools, and later on adding to these duties those of magistrate, that he dropped his research work—a source of grief to those who, like the present writer, knew what a loss this meant to science.

In the October of 1922 he retired from the service of the college, but in spite of frequent attacks of heart trouble and of the disease which ultimately proved fatal, he took up once more his interrupted algological studies and the following papers were published: "On the Structure of *Spyridia filamentosa*," *Annals of Botany*, 38, 1924; "The Ceramidium of *Polysiphonia*," *New Phyt.*, 23, 1925; "On Vacuolar Pseudopodia in *Callithamnion sp.*," *Rev. Alg.*; "On the genera Phyllophora, Gymnogongrus, and Ahnfeldtia and their Parasites," *New Phyt.*, 24, 1926; "On the Form of the Protoplast in Cells of the Genus Ceramium and those of *Dasya coccinea*," *New Phyt.*, 25.

During the past year Phillips suffered much from spinal trouble; he was taken to London and operated upon, but unsuccessfully; and on Dec. 2 he died at Leominster.

MR. S. M. EDWARDES, C.V.O., C.S.I.

THE premature death from bronchial pneumonia of Stephen Meredyth Edwardes, at the age of fifty-four years, which took place on Jan. 1 at Fielden, near Boxmoor, is a loss to the study of Indian history and archæology deeply to be deplored. Mr. Edwardes was a son of the Rev. Stephen Edwardes, fellow of Merton College, Oxford, and was educated at Eton and at Christ Church. In 1894 he passed into the Indian Civil Service, and was posted to the Bombay Presidency. The intimate acquaintance with conditions among the native population of the city which he soon acquired, and his profound knowledge of its history, on which he was widely recognised as the foremost authority, were employed to full advantage in his census volume of 1901, the additional volumes of the "Gazetteer" which he compiled between 1906 and 1910, and his "Rise of Bombay" and "Byways of Bombay." This knowledge, in combination with his personal qualities, made him eminently fitted for the post of Commissioner of Police, to which he was appointed in 1910. His well-balanced and admirably judicious "Crime in India," published in 1925, showed that no one could have been better qualified to represent India at the Geneva conference on traffic in women and children which he attended in 1921.

On his retirement, Mr. Edwardes became secretary to the Indo-British Association, an organisation formed to oppose the Montagu-Chelmsford reforms; but his chief interest lay in research. In 1923 he became joint editor with Sir Richard Temple of the *Indian Antiquary*. He revised Grant Duff's "History of the Mahrattas" and the fourth edition of Vincent Smith's "Early History of India." He was engaged in a comprehensive study of the Mogul period in collaboration with Prof. Garrett of Lahore, and in this field had already published a study of "Babur: Diarist and Despot." In 1926 he was selected to succeed Miss Ella Sykes as secretary of the Royal Asiatic Society.

SIR FRANCIS FOX.

BY the death on Jan. 7, at the age of eighty-two years, of Sir Francis Fox, the engineering world loses one of its oldest and most distinguished representatives. Four years younger than his brother Sir Douglas Fox (1840–1921), Sir Francis Fox was the son of Sir Charles Fox (1810–1874), whose earliest engineering experience was gained under Ericsson at the famous Rainhill locomotive trials and under Robert Stephenson on his London and Birmingham Railway; and he also became known as the constructor of the Great Exhibition building of 1851. From about 1860 onwards, father and sons were responsible for railways, bridges, and tunnels in both hemispheres, among which may be mentioned the Mersey Tunnel, the Liverpool Overhead Railway, the Great Northern and City, and Charing Cross and Hampstead Tubes; railways in India, Argentina, Canada, and Africa, and also the great bridge over the Victoria Falls on the Zambezi River. The firm in its earliest days was Fox, Henderson and Co., but was changed first to Sir Charles Fox and Sons and then to Sir Douglas Fox and Partners.

In his book, "Sixty-three Years of Engineering, Scientific and Social Work," Sir Francis Fox gives an account of many of these undertakings, and it is there he illustrates the remarkable accuracy with which tunnels can now be bored, the discrepancy in the tunnel between Hampstead Heath Station and Belsize Park, London, 4000 feet long, being only ½ in. In the case of the Simplon Tunnel, of which he was one of an international commission, the error was 3⅝ in. in 12½ miles.

In later years Sir Francis Fox did much important work in connexion with the preservation of old bridges, churches, and cathedrals; using the grouting machine for filling cracks and crevices in the masonry with liquid cement. In his valuable work on the preservation of Winchester Cathedral he was associated with Mr. T. G. Jackson, R.A. In 1912 he was also called upon to report on the condition of St. Paul's Cathedral.

No notice of the career of Sir Francis Fox, however, would be complete without reference to the social work for the less fortunate which he did in London with his brother. During the War, too, he visited the hospitals, lectured to the convalescent, and was instrumental in supplying large quantities of bandages by removing the linen from old engineering plans obtained from many sources. Knighted in 1912, Sir Francis Fox was twice married and leaves one son and three daughters, of whom the eldest, Dr. Selina Fox, was the founder of the Bermondsey Hospital and Medical Mission, a work in which Sir Francis took the greatest interest.

News and Views.

THE radio-telephone service between London and New York was opened successfully to public use on Jan. 7. Those who took part in the conversations for the first time were most favourably impressed by the clearness of the articulation, the voices of the speakers being at once recognisable. After sunset on Jan. 7 on the eastern side of the Atlantic the atmospheric conditions became very bad, which is quite an unusual occurrence for this time of the year. Yet still nearly all the subscribers who had booked times in advance were able to hold conversations. In six minutes the *Times* exchanged more than 600 words with its correspondent in New York, there being only one or two pauses for repetition. Sixty-eight years ago, Queen Victoria sent a message to President Buchanan at the rate of one word a minute, and eighteen years later Graham Bell talked to the future Lord Kelvin by telephone over the length of a room. Kelvin was filled with wonder, and pictured many developments which have come to pass. But even he never imagined that easily recognisable tones could be transmitted through 3000 miles of empty air without wires or cables almost as quickly as light. First we send signals, next we speak, and in the future we doubtless shall be able to see over thousands of miles. At present this long-distance telephone service is limited to telephone users in the neighbourhood of London and New York, but we look forward to this restriction being removed shortly, as telephone communication is now possible with towns on the Pacific Ocean. We do not think that differences in local times will have much effect on the traffic in long-distance communication.

THE sixteenth report of the Development Commissioners for the year ending Mar. 31, 1926, is arranged in four sections, the first two of which relate to the advances recommended for the development of agriculture, rural economy, fisheries and harbours, and describe the purposes for which these advances are being used. The third part relates to action taken in connexion with the compulsory acquisition of land, while the fourth deals with the financial position of the Development Fund at the close of the year. The research institutes, the activities of which are described, are the result of a scheme planned fifteen years ago, about half of them being already at work at the beginning of the War. After the armistice the interrupted programme was resumed, and there has since been a rapid increase, both in the scope of the work and in the financial needs of the stations. Grants in respect of maintenance from the Development Fund have increased approximately from £35,000 in 1919–20 to £160,000 in 1925–26. The original programme for establishing institutes has now been substantially completed, and although new branches of inquiry must be anticipated, it may be stated that a period of relative stability has been reached.

PARALLEL with the scheme for research institutes, a new plan has been developed for investigating local problems and providing advice for farmers. The principal extension in this case is in connexion with soil surveys, the agricultural departments having the co-operation of the Geological Survey. Developments have also occurred in another inter-departmental scheme, namely, that between agricultural institutes and the Meteorological Office, and some twenty stations are now carrying out investigations on the effect of weather on crops. In both these cases the methods of observation are of a tentative nature at present, and will, in all probability, be modified as the work extends. Variety testing of crops is a further important line of investigation which has only recently been developed, but work of this nature is already being carried out at five stations. As regard rural developments, the newly formed county rural community councils are proving successful. Both English and Scottish fishery departments, in addition to sharing in the general hydrographical and plankton investigations and statistical surveys organised by the International Council, are chiefly concerned with that part of the scheme which deals with the herring, cod, plaice, and haddock fisheries. Reports of the work done at the various laboratories are given, together with the papers published during the year. The experiment on land reclamation and improvement at Methwold, carried out at heavy cost to the Development Fund, is but briefly referred to, since a fuller report for the benefit of agriculturists is being prepared by the Ministry. The report concludes with a schedule of the loans and grants made in the past year, the total advances amounting to £558,392 as compared with £513,279 in the previous year (1924–25).

PROF. A. V. HILL, University College, London, Foulerton research professor of the Royal Society, is sailing on Jan. 15 for the United States, where he is to deliver a course of eight Lowell lectures at Boston during March, entitled "Living Machinery," and to act as visiting lecturer in chemistry at Cornell University for the semester February to May inclusive. The scheme of visiting lectureships at Cornell, arranged by Prof. L. M. Dennis through the generosity of Mr. G. F. Baker, enables the University each semester to bring men of science from abroad to work there; that is, to continue their researches and to give series of lectures upon them. Chemistry seems to be interpreted at Cornell in a liberal sense, for Prof. Hill is to work on the physiology of severe muscular exercise in man, using the Department of Chemistry as his headquarters, athletic students as experimental subjects, and the Department of Physical Training as an experimental ground. His lectures will deal with such subjects as speed of movement, rate of recovery, and the limits of muscular exertion. Prof. Hill is also to give two lectures at the Harvard Medical School, and one at the Yale Medical School, and to attend the annual meeting of the American Physiological Society in April. His two predecessors in the visiting lectureship at Cornell have been Prof.

Cohen of Utrecht and Prof. Paneth of Berlin. Prof. Hill expects to return to London at the end of May or beginning of June.

The Secretary of State for Scotland and the Minister of Agriculture and Fisheries have appointed a Wool-Breeding Council "to consider, and advise the Ministry of Agriculture and Fisheries and the Board of Agriculture for Scotland on questions relating to the improvement and utilisation of wool grown in Great Britain." The Council consists of representatives of the Ministry and the Scottish Board, of the woollen and worsted industries, of sheep breeders, and of scientific workers. The last are represented by Prof. A. F. Barker, Dr. S. G. Barker, Dr. F. A. E. Crew, Prof. Cossar Ewart, Sir Robert Greig, Mr. C. C. Hurst, Dr. Thomas Oliver, Prof. R. C. Punnett, Dr. James Ritchie, Prof. J. Lorrain Smith, and Prof. R. G. White. At a preliminary meeting held at Carlisle on Dec. 16, various aspects of sheep-breeding problems were discussed, and it was decided to obtain, as a guide for future breeding, the opinions of manufacturers as to the defects, from their point of view, in wool from the different breeds of sheep in Great Britain, and the directions in which improvement was desired. Preliminary statements were made as to the desirability of instituting certificates for rams with fleeces free from kemp, on lines similar to the certificates now issued for bulls under the Ministry's scheme. It was recommended further that cross-breeding experiments with unstable breeds of merinos should be discouraged, and that grants from public funds should be confined to institutes where there existed suitable facilities for properly controlled and observed breeding experiments.

It is now thirty-seven years ago since the earliest of the 'tube railways'—the City and South London Railway—was opened for traffic. It had an earthed return; that is, the electric current taken by the motors returned to the generators through the earth. When this railway was reconstructed two years ago, an insulated cable was provided for the return current. In an interesting paper by A. R. Cooper on the electrical equipment of the track on the underground railways of London, read to the Institution of Electrical Engineers on Jan. 6, the working results obtained by experience were summarised. In addition, extracts from Acts of Parliament, from the report of Lord Rayleigh's committee on vibration troubles, and from Duddell's reports (1913 and 1914) on sudden pressure rises caused by the accidental earthing of the positive rail, were given. It is generally supposed that the use of the track rails for returning the current is much cheaper than the installation of an insulated fourth rail. This is not necessarily true, as the fourth rail can carry currents for signalling purposes.

One of the most serious troubles in connexion with electric train working is due to ice forming on the conductor rails. Snow does not prevent the 'shoe' from collecting current; the breakdown occurs when there is a film of ice on the rails. This occurs when sleet falls on a rail the temperature of which is below freezing-point. Occasionally oil is fed on to the rails through the collecting shoes, and it is found that this sometimes prevents the ice from adhering. Consistent results, however, have not been obtained. To melt the ice from the rails, very heavy currents flowing for a considerable time have to be used, and so the method of electrically heating the rails is rarely employed. When the atmospheric conditions are such that trouble may be expected, a special car, fitted with steel strip brushes and oil sprays and hauled by a battery car, is used; but this method is not always effective. The loss in weight of conductor rails varies from 0·2 to 1·2 lb. per yard per annum. Mr. Cooper says that, in the interests of safety, it is desirable to change track rails or axles which have been affected by electric burns. He considers also that in the future it is very unlikely that any electric railway will employ the insulated return.

A short time ago the Gassiot Committee of the Royal Society appointed the Astronomer Royal, the Director of the Meteorological Office, and Dr. Chree, to consider what observations of terrestrial magnetism and atmospheric electricity should be made during the eclipse of June 29 next. The sub-committee met on Dec. 16, when the following recommendations were made:—*Terrestrial Magnetism.*—(*a*) That quick runs should be taken on all magnetographs in the British Isles during the period 4 h. to 8 h. G.M.T. on the three days June 28, 29, and 30. (*b*) The vertical force coils at Eskdalemuir and Lerwick should be in action if possible. (*c*) It was considered that field observations and eye observations of magnetic elements are not required. *Atmospheric Electricity.*—(*d*) Where possible the electrographs should be put on to quick run from 4 h. to 8 h. G.M.T. (*e*) As complete a set of eye observations of all elements of atmospheric electricity as can be arranged should be taken during the period 4 h. to 8 h. (*f*) The programme arranged for the day of the eclipse should be carried out on the previous and following days also.

Reports received from the Canadian Department of the Interior and from independent sources tell of the success which has followed the policy of transporting surplus bisons from Wainwright Park to Wood Buffalo Park, which by proclamation of the Governor-General on October 23, 1926, was constituted a Dominion Park with an area of 17,300 sq. miles. This was the sole territory of the only truly wild survivors of the American bison, a distinct species or race, the "wood buffalo," and among these, estimated to number some 1500, have now been dumped plains bisons numbering 1634 in 1925 and approximately 2000 in 1926. From the point of view of the Canadian authorities the experiment has proved a success: they have got rid of a surplus of 3634 plains bisons which were seriously overstocking Wainwright Park, and the transported animals have made good in the much more severe conditions of the North-West Territories. But from the scientific point of view the danger to which reference was made in Nature (Feb. 20, 1926, p. 275) still threatens. While, curiously enough, the 'wood buffalo' has to a large extent simply ignored the imported 'plains buffalo,' and, according to earlier advices received from Canadian correspondents, the two races have tended to segregate into two camps, there has already begun the cross-breeding which was feared, and which, in view of the now overwhelming superiority in numbers of the imported form, may end in modifying or swamping the distinctive characters of the little band of native stock. It may be added here that investigations being carried out by Prof. W. Rowan, of the University of Alberta, suggest that in the skeleton of the 'wood buffalo' there lie differences which clearly mark it off from the 'plains buffalo,' and confirm the distinctiveness of the two species, originally determined by external characters alone.

The second annual report, 1925–1926, of the Imperial Forestry Institute situated at the University of Oxford has been issued. This Institute is still in its first stages of existence, but the report gives evidence of some progress having been made within the past year. The idea underlying the creation of the Institute is to give post-graduate courses to men holding a degree or diploma in forestry and to provide refresher courses to forest officers on leave or who are deputed by their governments. The first object was already provided, we are given to understand, at other universities without any expense falling on the Treasury. The second could equally, and in fact actually was provided, at a university other than Oxford. The University of Cambridge, for example, has maintained that it is capable of conducting instruction up to the standard required. The fine buildings erected at universities outside Oxford, notably Cambridge and Edinburgh, have probably cost something in the neighbourhood of £40,000 and would be worth a far larger sum at the present day. These buildings are equipped for research. It appears from the report that the proposal is now put forward that a sum of £75,000 is to be spent on new buildings to accommodate this new Institute at Oxford. On the face of it the scheme appears to be a laudable one, Nevertheless, it would seem to demand further careful consideration if this money, or the bulk of it, is to be provided from the Treasury. Two points appear to demand a public and unbiassed inquiry before the Government is committed to the scheme; they are: (1) Are not the existing schools of forestry capable of giving all the education required, both up to the degree and post-graduate, and to undertake research? (2) Is it advisable to shut up forestry education in a water-tight compartment?

The resignation of Prof. A. W. Porter from the honorary secretaryship of the Institute of Physics was recently received by the Board of the Institute, and was accepted with great regret. Prof. Porter has been associated with the Institute from its inception, and its growth is largely due to his efforts. Prof. A. O. Rankine, of the Imperial College of Science, has been appointed to succeed him. Mr. Thomas Martin, who has recently held the positions of secretary of the British Empire Exhibition Committee of the Royal Society and of the Optical Convention, 1926, has been appointed secretary of the Institute. He succeeds Mr. G. S. W. Marlow, who has been acting secretary since the death of Mr. F. S. Spiers. The office of the Institute of Physics has been transferred to 1 Lowther Gardens, Exhibition Road, London, S.W.7, and all communications, including those relating to the *Journal of Scientific Instruments*, should now be sent to the new address. A tenancy of the premises to be occupied at 1 Lowther Gardens has been granted to the Institute, on very generous terms, by the Royal Commissioners of 1851; and the Commissioners, in placing this spacious accommodation at the disposal of the Institute, are giving great assistance to its work and to that of its participating societies.

The Air Ministry has issued an official communique giving an account, with full itinerary, of the Cape to Cairo flight of the Royal Air Force in 1925. The flight was composed of four aeroplanes under the leadership of Wing-Commander C. W. H. Pulford. A spare plane was sent to Aboukir, another spare plane and two engines were ready at Kisumu on Lake Victoria, and a third plane and four engines were ready in South Africa. Radio apparatus was not carried on account of its weight, its lack of value in Central Africa, and its demand for a skilled operator. The flight started from Heliopolis on March 1, and returned there from Cape Town on May 27, one day ahead of the time-table. The actual time of flying of the leader's aeroplane was 68 hours 21 minutes on the outward and 72 hours 34 minutes on the homeward journey. The flight was so successful that the account of it is almost devoid of incidents. The aeroplanes and engines proved equally reliable. The only repairs that were necessary were the replacing of one magneto, two airscrews and all the oil tanks. The whole flight of 14,000 miles was done on time in spite of the great range of climates that was traversed. On the return to Egypt the aeroplanes were flown to England.

The Italian National Committee for Geography has decided to raise funds for studies in Palestine. The studies will be mainly geographical, whereas similar institutions already in existence are mainly devoted to historical and archæological research. Some indication of the proposed work is given in the December number of the *Geographical Journal*. The first project to be undertaken will be the charting of the Dead Sea and the mapping of the Jordan trough on a large scale. Geological survey and limnological researches will also be carried out and it is proposed to take observations, over a long period, of changes in the bed of the Dead Sea and the meteorological conditions in the district. Other schemes include the foundation in Jerusalem of a library and collection of maps dealing with Palestine, and the publication of a series of memoirs especially with regard to old cartography, for which much material is available in Italy. The elaboration of the plan and the organisation of the expedition is in the hands of a committee under the chairmanship of Cav. Filippo de Filippi. The expedition is expected to start in November and has the sanction of the British Government and the Governments of Palestine and Transjordania.

To every one who has a receiving set, Pitman's "Radio Year Book" for 1927 will prove of great interest. It contains a great deal of information about British broadcasting and makes attempts to pierce the future. J. Swinburne gives a very characteristic 'pessimistic view' of broadcasting. He points out the fundamental error in the theory of universal education in art, literature, and machine reproduced music. Lavish endowment has little effect on the efficacy of education, or even of research. We can be improved only from the inside. "We cannot become musicians or even musical . . . by sitting with telephones over our ears, or near loud-speakers. No one can be improved, and he can improve himself only by hard work." J. L. Baird tells of the very rapid progress of television, and prophesies that televisors will be on sale before the end of this year. The cover of the book shows a domestic scene of a family gazing at the moving picture of a theatrical performer shown by the televisor and simultaneously hearing the words and music. 'Mentor' states that the day will come when we will be able to sit at home and see the Cup Final or the Derby; or possibly the record of these events will be bottled up and broadcast again during the evening for the benefit of the workers who have no time during the day to sit television gazing. For the last century the monotony of their lives has been driving the country dwellers to the lures and lights of the towns. Will broadcasting and television tend to stop this migration? Prof. J. A. Fleming gives practical details about insulators. He points out that there is considerable surface leakage on porcelain insulators when they are wet, and describes how to make a very simple and efficient insulator to replace them. The wiring of houses for radio reception in several rooms is described. A defect of the system is that any one listening on the telephones in one room will hear most of what is being said in other rooms where there are loud-speakers.

THE new magnetic observatory at Matochkin Shar (Novaya Zemblya), which is associated on the administrative side with the U.S.S.R. Hydrographical Department and on the scientific side with the Central Geophysical Observatory at Pavlovsk, has had considerable recent additions to its equipment. It now operates two sets of Eschenhagen magnetographs, one of higher sensitiveness, with scale values per 1 mm. of 1'·0 for declination (D), 6·6γ for horizontal force (H) and 5·4γ for vertical force (V); the other of lower sensitiveness, 1'·5 for D, 18γ for H, and 14γ for V. The magnetograph house has double walls of wood, and is maintained at a temperature of about 0° C. during the winter. The absolute instruments are housed in a separate pavilion free from iron. They consist of a dip inductor and two magnetometers, one for D, the other for H.

LORD BUCKLAND has promised to contribute a sum of £35,000 in seven annual instalments of £5000 to the National Museum of Wales, Cardiff. The donor has expressed the hope that this will enable the construction of the east wing of the building to be taken in hand. This range of galleries will cost, it is estimated, £46,000, and it is to be expected that Lord Buckland's generous gift will stimulate the growth of a fund which will make possible the completion of the whole of the projected museum buildings.

THE Faraday Society is arranging a general discussion to be held at Oxford on April 22-23 on "The Theory of Strong Electrolytes." The first day of the meeting will be devoted to ionic mobility and the second to the activity of strong electrolytes. In common with earlier discussions of the Faraday Society, the meeting will be distinguished by the presence of well-known scientific workers from the continental countries of Europe, and Great Britain will also be well represented. Accommodation for those attending the meeting is being arranged at Exeter and Lincoln Colleges, and it is hoped to obtain special facilities on the railways.

IN sending his appreciation of the work of Sir J. J. Thomson for our Cavendish Laboratory issue of Dec. 18, Prof. A. Sommerfeld asked that it should be printed in German unless contributions from other men of science abroad were also translated into English. Though we regret that this was not done, as the communications received from the Duc de Broglie, Mme. Curie, and Prof. Langevin were printed in French, yet we can assure Prof. Sommerfeld, who has written to us upon the matter, that no invidious distinction was thereby intended. The fact is that French is more familiar than German to most of our readers, and it was on this account alone that we printed the English translation of Prof. Sommerfeld's note. If contributions had been received in any other language than French, they would have been dealt with in the same way.

A NON-PARTY political literary periodical entitled *The London Weekly* (Price 6*d.*) has recently been started by the Commonwealth Review Ltd., under the editorship of Dr. L. Haden Guest, M.P. The first issue contained an article by Mr. L. S. Amery, Secretary of State for the Colonies, on "A Constructive Empire Policy," which is followed up in the second issue by an article on the same subject by Mr. Philip Snowden. We have also read an informative article by Florence B. Low describing the prospects for British teachers in Canada, while Major A. G. Church contributes an article entitled "Migration." Major Church discusses the migration of peoples within the British Empire, and makes a strong plea for the introduction of the scientific spirit into this problem. Every factor which has any bearing whatsoever on the question must be considered. In conclusion, he remarks that since agriculture is the main industry of the Empire, it is time that a systemic survey of its agricultural resources were made with the view of their proper development.

Imperial Chemical Industries, the great chemical merger formed by the amalgamation of Brunner Mond and Co., Ltd., Nobel Industries, Ltd., the United Alkali Co., Ltd., and the British Dyestuffs Corporation, Ltd., under the chairmanship of Sir Alfred Mond, is to make its first appearance to the public at the British Industries Fair organised by the Department of Overseas Trade at the White City, London, on Feb. 21–Mar. 4, where it will have the largest individual exhibit in the Chemical Section of the Fair. The main object of the exhibit is to make an expression of Imperial Chemical Industries' individuality as one group. It will be Imperial in its significance as showing the wide influence of the company in British commercial affairs. It will be practical in the sense that the man in the street will be able to visualise its numerous activities, and it will be scientific in the sense that the buyer of chemical goods will at once see the intimate relationship which exists between the products made in the factories belonging to the respective component parts of this great organisation.

Applications are invited for the following appointments, on or before the dates mentioned:—A junior technical officer at an Admiralty Experimental Establishment—The Secretary of the Admiralty (C.E. Branch), Whitehall, S.W.1 (Jan. 20). An assistant analyst in the Scientific Research and Experimental Department of the Admiralty—The Secretary to the Admiralty (C.E. Branch), The Admiralty, Whitehall, S.W.1 (Jan. 31). Two demonstrators in agricultural botany in the Department of Botany of the University of Leeds—The Registrar, The University, Leeds (Jan. 31). A director of the laboratories of the Clinical Research Association, Ltd.—The Secretary, Watergate House, York Buildings, Adelphi, W.C.2 (Jan. 31). A professor of anatomy in the University College of South Wales and Monmouthshire—The Registrar, University College, Cardiff (Feb. 26).

Our Astronomical Column.

Recent Sunspot and Magnetic Disturbance.—Several observers noted a spot on the sun's disc seen with the naked eye through the morning mist on Jan. 8. The spot was not an unusually large one, but it is of interest on account of the frequent changes which took place within the stream (of which the leader was the naked-eye object), and also its probable connexion with a magnetic disturbance recorded at Greenwich on Jan. 7 and 8. The most noticeable feature shown by the chief spot was a very bright tongue or 'bridge' which crossed the umbra from south to north on Jan. 3-8. On Jan. 7 this 'bridge' appeared to separate the whole spot nearly completely into two portions. The magnetic disturbance, of moderate intensity, commenced about noon on Jan. 7 and died out at 3 hr. on the following day. The greatest deviation of the declination magnet from its normal position was about 0°·5. The table of important spots for 1927 is continued as follows:

No.	Date on Disc.	Central Meridian Passage.	Latitude.	Area.
2	Jan. 2-14	Jan. 8·5	13° S.	1/1100 of sun's hemisphere.

As regards the sun's general activity, Mr. A. M. Newbegin writes, "Prominences continue active numerically, and metallic outbursts are occurring with much greater frequency, but the big displays of great prominences have not begun yet."

Weather Conditions in Norway for the Eclipse of June 29, 1927.—*Cracow Observatory Circ.*, No. 22, contains a useful note by K. Kordylewski and Z. Eckstein giving cloud-measures for various points in Scandinavia based on many years' observations (32 in some cases). The best conditions are found on the railway from Bergen to Oslo, and at Gällivare in northern Sweden. The cloud-ratio in these regions varies from 5 to 6, 10 being complete cloudiness. Finse has the best ratio, 5·0, and an average of 8 clear days per month. Vardo, in the extreme north of Norway, has the high cloud ratio 7·3, and 3 clear days per month. The experience of the 1896 eclipse in this region was not encouraging.

A New Photographic Star Catalogue.—The catalogues brought out by the Astronomische Gesellschaft, which cover the sky from 81° N. decl. to considerable S. decl., are known to all astronomers. It has now been determined (*Astr. Nach.* No. 5469) to form new photographic catalogues of the region from the North Pole to S. decl. 5°. The plan will be that adopted by Prof. Schlesinger of taking plates 5° × 5° on a scale of 1 mm. to 100″. The objectives will be 4-lens combinations by Zeiss with aperture 206 mm. Pulkovo will photograph the region 90° to 70° N. decl., the remainder being divided between Bergedorf and Bonn. Each observatory will measure its own plates, but the reduction of star places will be done at a single observatory. The re-observation of reference stars is being undertaken by six observatories. The work will begin in 1928, and it is hoped to finish it in three years.

The Distribution of Intensity in Stellar Absorption Lines.—An interesting account of pioneer work in this subject by Miss Payne and Dr. Shapley appears in the *Proceedings of the American Academy of Arts and Sciences* (vol. 61, No. 10) under the above title. A considerable amount of theoretical work has been done on the structure of absorption lines, and practical observations of this kind (which have hitherto been scanty) are of considerable importance. The spectra examined by the authors were all taken with the 16-inch refractor at Harvard, using two objective prisms and a range of different rectangular apertures. These spectra were analysed by a Moll thermo-electric microphotometer, and the intensities, as shown by the photographic tracings, were measured from reference lines (recorded on each tracing) representing 'darkness' and 'clear film.' A line representing the continuous background of the spectrum was drawn in each case by hand across the absorption line tracings, and the intensity drop from continuous background to line was measured graphically for various lines in the spectra of eleven stars. The principal object of this paper is to discuss the method of working and accuracy of the results obtainable. Some results of interest appear, however, even from these preliminary measures of eleven stars. In particular it may be mentioned that, even at the centres of the strong absorption lines of hydrogen and calcium, there is some residual light, of intensity averaging about twenty-five per cent. of the background light.

Research Items.

Sumerian Tablets.—The Manchester Museum has published copies of all of the "Behrens Collection" of Sumerian tablets excepting three, which are defaced and consequently useless. The complete collection contains 50 tablets from Drehem and Umma. The Drehem tablets, eight in number, tally in subject matter with the many others from this site which have been published, and deal with the daily business of Drehem. They contain records of animals for offerings. The Umma tablets belong to the same class, recording the daily details of the administration of animals, barley, and other products, wood, silver, and copper. As these tablets are contemporary, they afford a valuable source of information on Sumerian life and religion, while also serving to check the grammatical and religious texts composed later in Sumerian by authors who were not Sumerians, and when Sumerian had ceased to be the language of the people.

A European Parallel to the Durgāpūja.—Dr. Sten Konow, in the *Journal and Proceedings of the Asiatic Society of Bengal*, N.S., vol. 21, No. 3, argues that although the goddess Kāli is now usually considered to be of non-Aryan origin, there are features in Kāli worship which may point to the existence of an old, not only Aryan, but also Indo-European goddess going back to the time when Indian and European tribes were one people. This view is based upon the account given by Tacitus in the "Germania," ch. xl., of the worship of Nerthus—Mother Earth—by certain German tribes. The features of this worship essential for the purpose of comparison are the position of the priest as the husband of the goddess, the procession and the ablution in a sacred lake. The ceremony may be concluded to be a fertility rite. Various attempts have been made to arrive at a derivation of the name Nerthus. It is rarely used, and Sahlgren has suggested that it is an epithet employed instead of the real name, which was taboo. If so, it should be explained by some feature in the festival, and it is suggested that it is connected with the Sanskrit *Nart*, *Nṛt*, to dance, to act, *i.e.* a description of the symbolic or magic acting in the ceremony. The ideas connected with the base *nṛt* are connected with Siva, the consort of Kāli, the latter, however, playing the more prominent part in the popular fertility rites, she being the great Earth Mother comparable to the chthonic deities and demons of fertility elsewhere. The features of the Durgāpūja in which Kāli is worshipped include days of preparation and feasting, a ceremonial procession, and lastly an immersion in water, which men may not see on penalty of death. The deity comprises the male and female element, thus in herself personating the divine couple represented by the priest and Nerthus in the European parallel.

The Relation of Gonad and Plumage in the Fowl.—Messrs. Pézard, Sand, and Caridroit have demonstrated that in the case of the hen, if the amount of ovarian tissue is sufficiently reduced by operation, the female assumes the plumage characterisation of the male (*C. R. Soc. Biol.*, 92, 566 and 1034, 1924; 93, 1094, 1925; 94, 1074; *C. R. Acad. Sci.*, 177, 1087, 1924). F_1 hens out of a Brown Leghorn ♀ × Faverolle ♂ mating were used. The male plumage assumed was that of the Faverolle. The ovary regenerated, and associated with this increase in ovarian tissue the plumage again became as that of the female, first Brown Leghorn, later Faverolle. The authors argue that these serial changes indicate that the Brown Leghorn type of plumage coloration is a response to a lesser ovarian stimulus than is that of the Faverolle. They conclude that there are racial differences in the threshold of response. Evidence that the conception of differential thresholds of response to gonadic stimulus applied even to individual feathers was also obtained. The occurrence of feathers male on one side of the rachis, female on the other, led the authors to the conclusion that each side of the feather is ambivalent and that it can assume the male or female characters alike, but that the two sides at any given moment during development may not respond similarly to the same stimulus.

Homology of the Ala Temporalis and Alisphenoid Bones.—Dr. Kesteven (*Jour. Anat.*, vol. 61, pt. 1, 1926) discusses at some length the homologies of these bones in the vertebrate series. With regard to the ala temporalis, he concludes that this bone in mammals has been derived from and is homologous with the pila pro-otica of the lower vertebrates. In this conclusion he is in opposition to the views of Broom, which are accepted by Watson, Gregory, and Noble, who regards this bone as a remnant of the palæopterygoid cartilage. As to the alisphenoid bones, the author concludes that they are homologous throughout the whole craniate series. While accepting the views of Gregory and Noble that the so-called epipterygoids of the cynodont reptiles are homologous with the alisphenoid bones of mammals, he denies that they are homologous with the epipterygoids of other reptiles.

Oceanography of the Baltic and Fishery Research.—The current quarterly number of the *Journal du Conseil permanent pour l'exploration de la mer* is mainly devoted to accounts of the water movements in the Baltic and its entrance into the North Sea. Prof. Otto Petterson discusses fluctuations occurring between one year and another in the inflow of the salter North Sea water, which passes in as a bottom current, carrying with it fish of considerable economic importance to the Baltic fisheries. Evidence of long-period fluctuations in the herring fishery is cited, and these are attributed to secular fluctuations in the tide-raising force. Dr. Palmen has applied Bjerknes' circulation theory to hydrographic observations made in the Gulf of Finland, and finds fair agreement between the currents calculated by this means and those observed. The determination of the age of cod from the number of 'winter rings' in its scales has presented difficulties owing to the formation of false rings during an unfavourable period in the life of the fish, such as may be brought about by temporary lack of food. Mr. Graham outlines a method which assists in distinguishing between such false and the true winter ring during the first year's growth, and hopes to extend the application of the method to older fish.

Devonian Volcanic Rocks of New Brunswick.—The *Bull. Geol. Soc. America* of Sept. 30 contains an interesting account by W. V. Howard of the Devonian rocks near Dalhousie, New Brunswick. The volcanic rocks include andesites, dacites, latites, and associated tuffs. Six excellent analyses reveal an unusual richness in soda for rocks of these types, and it may be significant, as the author points out, that some of the pre-Cambrian rocks of New Brunswick and Maine share the same characteristic. Despite this, however, there is no evidence of consanguinity between the Dalhousie volcanics and those of the contemporaneous Aroostook series in Maine. Yet there is a striking resemblance, both mineralogically and chemically, between the rocks of the Dalhousie eruptions and those of the Pentland Hills and other Old Red Sandstone volcanic districts of Scotland. This resemblance extends even to the curious detail that on both sides of the Atlantic the volcanic series of this epoch are free from the great swarms of dykes which are usually found around ancient volcanic centres.

A New Desensitiser for Photographic Plates.—"Jute Red" (or Red 39,651) is a mixture of dyes which dissolves readily in lukewarm water to form a one per cent. reddish-orange solution. It is supplied by the Soc. Anon. des Matières colorantes de St. Denis, of Paris. M. Rene J. Garnotel claims (*British Journal of Photography*, Dec. 17) for it that it has many advantages over previously known desensitisers when applied to either negative or positive emulsions. If the skin or nails get stained by it the colour is entirely removed by a short wash with soap and water. Its aqueous solution (1 part in 5000) replaces some of the water of the developer formula without any risk of the precipitation of any constituent, and this is not only a simpler method of working than the use of a preliminary desensitising bath, but also does not interfere at all with the Watkins' factorial method of development. Formulæ are given for its use with M.Q. developers and for autochromes. The dye is completely eliminated in the ordinary course of washing in all cases.

Menthones and Derived Substances.—A noteworthy advance in the chemistry of the menthones and derived substances is recorded in the Sept. issue of the *Journal of the Chemical Society*. A short while ago Prof. John Read and Miss A. M. R. Cook were successful in isolating a number of pure derivatives of *dl-iso*menthone, starting from the eucalyptus ketone, *dl*-piperitone. They have now extended their operations to the preparation and characterisation of *dl*-menthylamine, *dl-neo*menthylamine and *dl-iso*menthylamine. In a further paper, by Prof. Read and Dr. G. J. Robertson, corresponding derivatives of the pure optically active forms of these bases are described, and a scheme is advanced for representing their relative molecular configurations. Certain striking similarities between the menthylamines and the *iso*-menthylamines are correlated with their closely similar molecular configurations, which differ only in the disposition of the groups about one of the three asymmetric carbon atoms concerned; a parallel relationship is anticipated between the *neo*-menthylamines and the as yet unknown *neo-iso*menthylamines. A new optically inactive menthol is also mentioned by Prof. Read and Miss Cook, and it is likely that additional information on the stereochemical relationships of this important group will be forthcoming as a further consequence of these interesting researches. Incidentally, a fuller knowledge of the chemistry of the terpene group as a whole should result; and it seems that Prof. Read and his assistants have opened up what may prove a very fruitful field of investigation.

Polarisation of Light emitted by Positive Rays.—E. Rupp (*Ann. der Phys.*, No. 22, p. 615, 1926) has recently examined the variation of the polarisation of the light, emitted by a beam of positive rays of decreasing intensity, with the angle at which the beam of positive rays was observed. He dealt with positive rays of hydrogen, helium, and lithium, since these atoms possess the simplest electron structures. The results showed in general that the light polarised with its vector parallel to the beam of positive rays increased in intensity with the angle of vision. When observed in a direction at right angles to the beam, the intensity of the light polarised parallel to the beam was always greater than that of the light polarised at right angles thereto. The variation of the polarisation was greatest for hydrogen positive rays, and was more pronounced for higher velocities of the rays. In the case of helium and lithium rays the variation depended on the spectral series to which the emitted light belonged. Rupp considers that there is probably some connexion between the polarisation of the light emitted by a beam of positive rays of decreasing intensity and the polarised light produced by a beam of parallel electrons which has been studied by Kossel and by Skinner. In fact, the results could be expressed by saying that atoms, moving in a regular manner through an arbitrary arrangement of molecules or electrons, make impacts which result in the emission of polarised light.

Optical Constants of Optical Glass.—The catalogue of optical glass recently issued by the Parsons Optical Glass Company, of Little Chester, Derby, marks an important departure from tradition. The foundations of the usual method of specifying the optical constants of glass date from more than one hundred years ago, when Fraunhofer succeeded (about 1813) in measuring the refractive indices of his telescope glasses for some of the chief dark lines of the solar spectrum. Since that time it has been very usual to achromatise a lens such as a telescope object glass for visual observation by uniting the foci for the C and F lines. Photographic achromatism is usually secured by uniting D and G^1 (the latter being a line of the hydrogen spectrum). The choice of the wave-lengths for achromatism has, however, been periodically discussed, and has been criticised by Gifford and others. Certain conditions for visual achromatism used in optical designing by some workers, such as Conrady, have hitherto necessitated a certain amount of preliminary calculation for the refractive index for "the wave-length of brightest light" in the solar spectrum, approximately $0{\cdot}555\,\mu\mu$, which must be done with the aid of a suitable interpolation formula. Furthermore, the refractive indices hitherto listed have not supplied sufficient indication of the variation of focus with wave-length when achromatism is so established that the minimum focus falls in the regions of shorter wave-length for photographic purposes. This catalogue, following the suggestions of Hasselkus, makes use of five lines in addition to the usual ones, two of helium at $706{\cdot}5\,\mu\mu$ and $587{\cdot}5\,\mu\mu$, and three of mercury at $546{\cdot}1\,\mu\mu$, $435{\cdot}9\,\mu\mu$, and $404{\cdot}7\,\mu\mu$ respectively. The standard refractive indices are listed for the helium line, $587{\cdot}5\,\mu\mu$, which is capable of more satisfactory performance on the refractometer than the double line of sodium. By the aid of this additional information the computer's task should be considerably facilitated, though the mercury green line at $546\,\mu\mu$ is decidedly on the short side of the maximum visual intensity, and a little experience will be needed to make the best use of the additional information. There is little need to direct attention to the wide and useful range of optical glasses now offered; the firm is prepared to make up intermediate types of glass to customers' requirements.

Annual Exhibition of the Physical and Optical Societies.

THE seventeenth annual exhibition of the Physical and Optical Societies was held on Jan. 4, 5, and 6 at the Imperial College of Science, London, and covered a wide range of electrical, optical, and other physical apparatus. This exhibition has rightly come to be regarded as an opportune occasion for the various manufacturing firms to bring to notice their latest improvements, and this year's exhibition reflects great credit on the ingenuity and originality in design and excellence of workmanship of the apparatus shown. There is an atmosphere of courtesy and entertaining informality in these annual events which cannot fail to enhance the interest of the visitors and evoke their admiration. Prof. A. O. Rankine, as secretary, is to be heartily congratulated on his success.

Seventy-four firms exhibited apparatus, and it is regretted that the limited space available in this journal does not permit mention of all the instruments. Reference may be made to the illustrated catalogue of the exhibition for fuller details, and some exhibits embodying new features are noted below.

The attractive lectures in the evenings, and subsections devoted respectively to recent results in physical research, lecture experiments in physics of special interest to teachers, and famous historical physical experiments again appeared in the programme.

The lecture on the first evening was by Prof. E. N. da C. Andrade on light and electricity as it might have been given in 1709 with the apparatus of the time, and, it may be added, under conditions which were dramatically realistic and were greatly appreciated by the audience. The lecturer, who impersonated Francis Hauksbee, and his assistant Mr. Paul, appeared in the picturesque costume of the period, and the hall was appropriately illuminated by candles, which were lighted by flint-and-steel and tinder box. All the experiments were repetitions of those actually performed by Francis Hauksbee, a contemporary of Newton, and were selected as having particular relation to present-day concepts of the electrical constitution of matter. The electric glow accompanying ionisation when matter is finely subdivided *in vacuo* was demonstrated with such simple apparatus as vessels containing oil or mercury and partially evacuated, and then shaken; a mercury jet *in vacuo*; and a rotating glass globe rubbed by the hands. By courtesy of the Royal Society, the actual air pump made and used by Hauksbee was employed in the lecture. This treasured veteran of pioneer apparatus, quaint in design and portraying the combined efforts of wood-turner, joiner, and engineer, was successfully coaxed by Mr. Paul to resume duty after more than two centuries, to the accompaniment of a few merry clanks due to the hand-cut gears, with perfect results.

On the second evening a discourse was given by Dr. C. V. Drysdale on "Progress in Electrical Instrument Design and Construction." Reference was made to the many improvements introduced by Profs. Ayrton and Perry some forty years ago, the more modern improvements being due to the utilisation of new materials possessing properties valuable in instrument design, for example, synthetic resins, chromium gells, and magnetic alloys of the chromium-steel and nickel-iron class. A demonstration was given of the effective magnetic screening afforded by mumetal, and reference was made to the use of this alloy in transformer design on account of its high permeability and low hysteresis. The necessity of studying the bearing of basic formulæ in instrument design was emphasised in the application to d.c. and a.c. instruments and machines, conductors, etc.

The lecture on the third evening was delivered by Mr. J. L. Baird on "Television." The development of this difficult branch of physics was traced from its inception in the early part of the present century down to work done barely twelve months ago. One of the first attempts was a model of the eye comprising sixty-four selenium cells and made in 1906. Later came the single cell in conjunction with an exploring beam produced by vibrating mirrors, then the photo-electric cell replacing the selenium cell; still later the cathode-ray tube was added to the combination of mirrors and cell, and then the rotating prismatic disc replacing the mirrors. A résumé of the lecturer's own research then followed. His apparatus comprises direct current and alternating current motors, lenses spirally arranged on a rotating disc coacting with a slotted disc, and a photo-electric cell, the current variation of which is utilised in the wireless transmission of the image. Reception is effected by similar means. A model of the transmitting portion of the lecturer's original apparatus used in 1925 was on exhibition, and no doubt the bulkiness of the complete plant precluded an actual demonstration. The discourse was repeated the same evening, but one item not referred to in the lecture should be recorded, namely, that Mr. Baird successfully effected the transmission of moving images of human faces at the Royal Institution on Jan. 27, 1926.

The research and experimental section inaugurated at the annual exhibition last year again proved instructive and of special interest in indicating the trend of progress in the application of modern physics to the arts and manufactures. The Research Association of British Rubber and Tyre Manufacturers exhibited a sieving apparatus for the detection and estimation of grit in fine powders by means of wire gauze and a stream of water. The British Research Association for the Woollen and Worsted Industries included in its section a balance for estimating moisture regained by textile materials in drying ovens, an electrical device for controlling room humidity, and a roller setting gauge. The Admiralty Research Laboratory supplied eight exhibits, comprising phonic signalling apparatus, a camera of the revolving-drum type for use with an oscillograph, and other electrical apparatus used in tests involving sonic frequencies. The development of fog-signalling and sound-locating apparatus was illustrated by the Air Defence Experimental Establishment.

Devices for solving practical difficulties continually arising in specialised technical operations were shown by the following firms and institutions: Mr. Conrad Beck, microscope aberration tests; Dr. G. D. Bengough and Mr. J. M. Stewart, protecting and colouring aluminium; the Brown-Firth Research Laboratories, chromium steels; Prof. W. Cramp, a magnetic balance; Mr. H. Dewhurst, a rapid bolometer in operation; The General Electric Co., Ltd., optical and electrical apparatus; Mr. Hallimond, a magnetic separator; W. T. Henley's Telegraph Works Co., Ltd. (Research Dept.), wire and cable testing and phenomena; Metropolitan-Vickers Electrical Co., Ltd. (Research Dept.), valves, electric furnaces, chromium plating, welding, etc.; The National Institute for the Blind; the National Physical Laboratory; and The British Thomson-Houston Co., Ld., together contributed an important collection.

The lecture experiments in physics comprised working models designed to illustrate wireless phenomena; synchronous and induction motors; three-phase currents; wave motion; and magnetic fields. Other apparatus demonstrated cloud experiments, condenser capacity by analogy with models immersed in a solution of copper sulphate, and the rotation of bodies with dielectric surfaces when suspended between the poles of a Wimshurst machine.

In the section devoted to famous historical experiments, Prof. E. V. Appleton exhibited a coil from King's College and used by Joseph Henry in his work on self-induction; Sir Charles Wheatstone's step-by-step telegraph designed in 1840, and a variable resistance box and bridge by the same inventor; and James Clerk Maxwell's model illustrating the induction of currents; while Sir William Bragg exhibited apparatus used by Tyndall in his investigation on so-called spontaneous generation.

Of the almost bewildering assemblage of apparatus, the following exhibits are selected for particular notice: C. Baker, for epidiascopes; The Cambridge Instrument Co., Ltd., an oxygen recorder for boiler feed water, a carbon dioxide recorder for flue gases, a magnetic bridge permeameter, and a glass electrode potentiometer; Crompton and Co., Ltd., their "S.M.S." hygrometer and new wattmeter; W. Edwards and Co., rotary vacuum pumps; Adam Hilger, Ltd., the Guild trichromatic colorimeter and spectrographic apparatus; H. Hughes and Sons, Ltd., echo-sounding gear; Klaxon, Ltd., the 'Audiwave' machine for relieving deafness; Negretti and Zambra, meteorological and electrical appliances; L. Oertling, Ltd., special physical balance with 22 ft. light beam; Ogilvy and Co., dark ground condenser, 1·20 N.A., objectives, and colorimeter; H. Tinsley and Co., electrical and stroboscopic apparatus; and Carl Zeiss (London), Ltd., the "Bitukni" binocular microscope attachment, microscope stand G, Nordenson photographic ophthalmoscope, and direct vision monochromator with wave-length scale.

H. W. H.

The Science Masters' Association.

At the kind invitation of the Vice-Chancellor of the University, the annual meeting of the Science Masters' Association was held at Oxford on Jan. 4-7. The membership of the Association has grown rapidly in the last few years, and at this, the twenty-seventh, annual meeting, some 450 members were present out of a total of 1200. Formal proceedings opened on Tuesday evening, when Brig.-General H. Hartley delivered his presidential address in the large hall of the City of Oxford School. Choosing as his subject the rise and development of the ionic theory, the president gave a masterly survey of both the fundamental work and recent advances, pointing out the way in which the difficulties presented by strong electrolytes are being overcome. To the evident relief of his audience, General Hartley said that practically no change was necessary in the method of teaching elementary work on the theory. On the motion of Sir Richard Gregory, seconded by Mr. H. A. Wootton, a hearty vote of thanks was accorded the president for his address, but much to the disappointment of the Association Prof. H. E. Armstrong, who was present, could not be prevailed upon to speak.

On succeeding days, lectures on various scientific subjects were given by members of the University of Oxford and others, two of the most attractive being that of Prof. E. B. Poulton upon "Protective Mimicry in Insects" and that of Prof. H. H. Turner upon "Eclipses" with special reference to the forthcoming total solar eclipse visible in England. Prof. Poulton's lecture, to judge from the applause it evoked, met with warm appreciation. It was admirably conceived and delivered, and was illustrated with a large number of exquisite lantern slides. We believe it should have been of the greatest value to science teachers, in that it showed how natural history may be made to afford a sound training in scientific method in an extremely attractive way.

The Association was fortunate in securing Prof. Turner's lecture on the total eclipse, not merely on account of the intrinsic value and interest of the lecture, but also because Prof. Turner demonstrated in an inimitable way how difficult astronomical conceptions could be made clear to boys and girls. He captured his audience at once with his small spheres for the earth and moon, indiarubber balloon for Jupiter, and large carriage-umbrella for the sun. After a very lucid description of the causes of eclipses in general, he related the story of several famous examples of the phenomenon, winding up with a graphic account of the Einstein eclipse of 1919. He then described the course of the total eclipse of June next, and urged upon teachers the importance of making arrangements to allow as many of their pupils as possible to see this event, which is likely to prove unique to most Englishmen now alive. Prof. Turner suggested that camps should be formed in suitable spots along the course to accommodate children for the preceding night, and said that he had been in communication with the Board of Education and with the authorities of the Boy Scouts' Association. It is desirable that arrangements should be made some time in advance, and science teachers would do well to lay the matter before their respective headmasters and headmistresses at the earliest opportunity. Fortunately, the date of the eclipse (June 29) does not clash with matriculation, school certificate, or higher certificate examinations, and we therefore hope that the school authorities will view with leniency any alterations in routine which may be necessary.

Through the efforts of the president and of the local secretary, Mr. H. R. Raikes of Exeter College, visits were made to the various colleges, the Bodleian Library, the Clarendon Press, the Morris Works at Cowley, and other places of interest. The wonderful collection of historic scientific instruments at the Old Ashmolean proved very popular, and one heard on every hand the wish expressed that some one would do for Cambridge what Dr. Gunther has done so excellently for Oxford. The collection is rendered additionally valuable by the series of "Old Ashmolean Reprints" now in course of publication, and by Dr. Gunther's small but delightful handbook.

In the Clarendon, electrical, and other laboratories, demonstrations and exhibits had been prepared by members of the University. This feature, which entails a great deal of work on the part of the demonstrators and exhibitors, is always warmly appreciated by members of the Association, who find it of the greatest value as a concentrated refresher course and as a source of new ideas with which to infuse their school lessons.

As in previous years, there was an exhibition of scientific books and apparatus. On the table reserved for books written by members of the Association there were no less than forty-nine exhibits, a number which says much for the enthusiasm and literary energy of our teachers of science. It was pleasing to note that these books were by no means all text-books; some dealt with the history of science, some with science in its more general aspects, and one at least—Dr. I. B. Hart's well-known book on the mechanical investigations of Leonardo da Vinci—was evidence of sound and exacting original research.

The large size of the publishers' exhibit was an unmistakable sign of the importance they attach to this annual meeting. In spite of many counter-attractions, their stalls were always surrounded by crowds of members, and if the keenness of the latter on the latest literature of their subjects is any indication of their educational ability, science teaching in the schools of Great Britain is by no means in the parlous state described intermittently by one or two pessimists. The same interest was shown in the excellent exhibit of scientific apparatus staged by the principal firms; it was clear to an observer that many masters had waited for the exhibition before giving orders for apparatus, and were now busily engaged in spending their grants to the best advantage. The epidiascope, an instrument of incomparable educational value, was a principal focus, and though the price is still too high for a good many schools, we imagine that the makers must have been very well satisfied with the result of their exhibit.

At the business meeting of the Association, held on Thursday morning, the most important step was the alteration of the membership rule to include, under certain conditions, science masters not at present eligible. The chairman, Mr. E. J. Holmyard (Clifton), pointed out that if the Association is to retain control of science teaching in the boys' schools of Great Britain, it is essential that no one doing appropriate work should be ineligible; at the same time, the moment is not opportune for any radical change in the required qualification for membership.

The president and chairman of the Association for 1927 are Sir Thomas Holland and Mr. C. E. Sladden (Eton College) respectively. Before the close of the meeting the members unanimously and enthusiastically asked the chairman to convey a message of congratulation and good wishes to Canon J. M. Wilson, one of the pioneers of science teaching in England and a man whom the whole association holds in affectionate regard. A sympathetic reference was also made to the death of Sir William Tilden, president of the Association in 1904.

At the end of the meeting the chairman, on behalf of the Association, conveyed a very hearty vote of thanks to the Vice-Chancellor of the University of Oxford for the splendid hospitality with which the University had received its members.

University and Educational Intelligence.

St. Andrews.—University College, Dundee, will benefit to the extent of £25,000 under the will of the late William Gibson of Ellieslea, Broughty-Ferry, Dundee. This sum becomes payable on the death of the testator's two sisters, and is to be used to build and equip a laboratory for study and research in pathology and bacteriology.

A course of four free public lectures on "The Total Eclipse of the Sun in June in Northern England" will be given by Mr. A. R. Hincks at Gresham College, Basinghall Street, E.C.2, on Jan. 18, 19, 20, and 21 at 6 o'clock. No tickets will be required.

On and after Jan. 17 a new series of conducted tours will be started for school teachers in the exhibition galleries of the Imperial Institute. Guide lecturers will meet parties of school teachers at 3 p.m. daily, except Saturdays, at the east and west entrances, and conduct them through the various courts, indicating the utilisation and economic value of the various products which are exhibited. It is hoped that teachers will bring at a later date organised parties of school children from their schools and give them practical lessons in economic geography and Empire development in these galleries. Head teachers who wish to send representatives from their schools should make application in writing to the Secretary, Imperial Institute, South Kensington, S.W.7, at least three days in advance. The guide lecturers will also be available to conduct parties of school children at 10 a.m. and 11 a.m. daily, except Saturdays; each party should be limited to about twenty children, accompanied by a teacher. Applications for dates for these tours should be made in the same way to the Secretary, Imperial Institute, South Kensington, S.W.7.

Accredited colleges and universities in the United States are listed in Bulletin 1926, No. 10, of the Bureau of Education. The lists represent, not national governmental approval, for the Bureau makes no attempt to rate or to standardise the collegiate institutions of the country, but recognition by a number of voluntary agencies and by State universities and State departments of education. It is on these lists that all who desire to learn the standing of colleges and universities in the United States must rely for information. A notable step towards the standardisation of the methods employed by these accrediting agencies was taken in 1922 when the American Council on Education, pursuant to the recommendations of a report approved by a conference held in 1921, defined standards for accrediting colleges, junior colleges, and teacher-training institutions. These standards have been adopted in entirety or with certain modifications by the several national and regional associations and by a number of the State departments of education and Church boards of education. Of these associations, the best known outside America is the Association of American Universities. This body has signified its approval of 171 institutions, of which 34 are universities of complex organisation, usually with graduate schools 16 technological institutions, and 121 colleges. These lists are also given in the "Universities Year-book of the British Empire."

The New Education Fellowship (11 Tavistock Square, London, W.C.1) is organising a fourth world conference, to be held at Locarno on August 3-17 next. The general theme of the conference is to be "The True Meaning of Freedom in Education." Among the speakers and group leaders are to be Profs. Bovet of the University of Geneva, Decroly of Brussels, Lombardo-Radice of Rome (editor of *L' Educazione Nazionale*), and Carson Ryan of Swarthmore, the editors of *Das werdende Zeitalter*, Dr. Alfred Adler of Vienna, author of "Individual Psychology," Dr. Adolphe Ferriere, editor of *Pour l'Ère Nouvelle* and founder of the International Bureau of New Schools, and several people actually engaged in the teaching of children. The announcement explains that although much of the conference proceedings will be devoted to problems of the teacher in relation to the child, yet time will be given to the discussion of the personal problems of the teacher, who, it is pointed out, needs to study the art of true freedom; this comes not from unrestraint but from right inner control. The Fellowship aims at discovering the principles of this art both for the child and for the teacher. Time is to be given to investigating the problems of the secondary school and to discussing how far progressive methods can be applied to them without prejudicing examination results. The organisers, mindful of the urgent need of what a contributor to the *Times Educational Supplement* of Dec. 4 calls "a triple alliance" of parents, teachers, and employers, have provided for attention being given not only to the child at the school and in the home but also to post-school problems.

Calendar of Discovery and Invention.

January 16, 1834.—After a voyage of two months from Portsmouth, Sir John Herschel, on Jan. 16, 1834, reached Cape Town. Re-erecting his famous 20-feet telescope at Feldhausen, near the base of Table Mountain, during the next four years he carried out his great survey of the southern hemisphere, observing more than 4000 nebulæ and star clusters, and 2095 double stars. He also made many observations of relative stellar brightness, of Halley's comet, of the satellites of Jupiter, and of sunspots.

January 17, 1783.—Of capital importance in the industrial development of Great Britain were the two inventions of Henry Cort—the rolling mill and the puddling furnace. The former was patented on Jan. 17, 1783, the latter on Feb. 13, 1784. Dudley, the Darbys, Huntsman, and others, had improved the methods of making cast iron and steel, but the main British supply of wrought iron came from Sweden and Russia. Cort's improvements were the results of years of work at his foundry at Fareham, but no sooner had he brought out his invention than misfortune befell him and he was completely ruined. England, however, benefited immensely by his work, and by 1860, just before the Bessemer process was taken up, there were 8000 puddling furnaces in use.

January 17, 1867.—On Dec. 4, 1866, Werner Siemens had written to William Siemens: "I have had a new idea, which in all probability will succeed and may give important results." What that idea was, was disclosed in a paper read to the Berlin Academy of Sciences on Jan. 17, 1867. Werner Siemens then described the first dynamo. In sending the description to his brother for the Royal Society, Werner remarked: "It is successful beyond expectation even in small dimensions. It will be a most important thing." Wheatstone's invention of the dynamo was contemporary, but Werner Siemens was the first to publish particulars of such a machine.

January 18, 1799.—Paper-making is one of the oldest industries, but the first to invent an endless paper-making machine was Louis Robert, an employee of François Didot, of Essones, France. A patent was granted to Robert on Jan. 18, 1799, and in the following years the French Government awarded him 8000 francs. The first machine, however, was made by Hall, of Dartford, and in 1804 the patent was purchased by Henry Fourdrinier, who spent £60,000 on improving it. In England at the present time there are about 260 paper-mills, with a total annual output of 1¼ million tons of paper.

January 20, 1881.—The evolution of the solar system is regarded as one of the most interesting questions presented by modern astronomy, and to this question G. H. Darwin devoted many years of his life. One of his most important papers was read to the Royal Society on Jan. 20, 1881. He showed that in consequence of the effects of tidal friction, the evolution of the earth and moon had been probably unique in the solar system and concluded that as a result of the tides our day and the time of revolution of the moon in its orbit are both lengthening.

January 21, 1795.—During the French Revolution the Committee of Public Welfare took up the matter of education. In September 1794 it was decided "there should be established in Paris a normal school where instruction in the art of teaching science should be given to persons already possessing scientific knowledge." Through this came the foundation of the École Normale, which began its work on Jan. 21, 1795.

E. C. S.

Societies and Academies.

LONDON.

Linnean Society, Dec. 2.—**J. Ramsbottom**: The Society of Amateur Botanists. Mordecai Cubitt Cooke (1825–1914) was appointed head master of the new Trinity School, Lambeth, at the age of twenty-three years. Here he conducted evening botanical classes under the old Science and Art Department. In the later 'fifties he occasionally took his pupils for country rambles. Afterwards they were joined by outsiders, and in 1860 constituted themselves into the Society of Amateur Botanists. This was planned for excursions, interchange of specimens, communication of papers, and the establishment of a library, herbarium, and museum. Cooke was the first and only president. Excursions were held on alternate Saturdays and meetings on alternate Wednesdays. The meetings were held first at the Metropolitan Club, Edgware Road, and then over the shop in Piccadilly of Robert Hardwicke, the publisher of natural history works. A letter in the first volume of *Hardwicke's Science Gossip* (1865) from W. Gibson, suggesting an association of amateur microscopists "something on the plan of the Society of Amateur Botanists," led to the formation of the Quekett Microscopical Club. The new club enrolled 155 members in its first year. Excursions were carried out as with the Society of Amateur Botanists, many of whose members joined the new club. The Society languished and may be said to have been killed by the Quekett.—**C. E. Salmon**: Some interesting British plants. *Myosotis brevifolia* Salm. is a new species, found in marshes in the Cross Fell district, and bearing short, broad, blunt leaves; it produces numerous rooting stolons above ground; its corolla is pale blue, almost as large as that of *M. repens*, the calyx is deeply divided, rather more than half-way, and the segments are oblong, rounded or blunt at the apex; its style is very short. Other plants were also described.

Dec. 16.—**E. Ashby**: Notes on the flora of the Grampian Mountains of Victoria, Australia. The range is situated in Western Victoria, and covers an area of about 60 miles by 30 miles; the rocks are sandstone, with quartzite and intrusive rock in a few places. It forms an ecological islet rising abruptly from hundreds of miles of undulating plains, and is a meeting-place of the east and west as regards its flora. Fifteen species are endemic, including four species of the Leguminous genus Pultenæa, and a terrestrial orchid, *Caladenia iridescens*, which flourishes high up in the barren stony mountain soil.—**W. T. Calman**: The giant teredo. The giant teredo, *Kuphus arenarius* (Linn.), first described by Rumphius two hundred years ago, has hitherto been known chiefly by its massive shelly tube, which may be so much as four feet in length and three inches in diameter at the wider end. A complete specimen was collected by Capt. Burgess, of the Mission steamer *Southern Cross*, in the Solomon Islands. It comprises some thirteen inches of the posterior end of the body, with the siphons and pallets. Instead of boring in wood like the other Teredinidæ, Kuphus lives embedded in the mud of mangrove-swamps, with the siphons projecting from the surface. Possibly it is the full-grown condition of a timber-boring species (perhaps *Teredo mannii*) which is set free by the decay of the wood.—**J. R. Norman**: Ambicoloration and associated variations in flat-fishes. Ambicoloration in flat-fishes is of particular interest on account of the other variations towards symmetry which accompany complete (or almost complete) pigmentation of the blind side. The modification of the scales on the blind side to resemble those of the ocular side in the dab, and the development of bony tubercles on the blind side of the body in the turbot are characteristic variations of this nature. Another correlated variation is the delayed or arrested migration of the eye, which leads to the formation of a characteristic fleshy hook on the head. In the southern flounder of Australia, in which only a single pelvic fin is normally developed, two symmetrical pelvics of equal size are present in completely ambicolorate examples. The tendency is for ambicoloration in flat-fishes to affect the head last of all.

Geological Society, Dec. 15.—**J. H. Davies** and **A. E. Trueman**: A revision of the non-marine lamellibranchs of the Coal Measures, and a discussion of their zonal sequence. The Coal Measure lamellibranchs of the genera Carbonicola, Anthraeomya, and Naiadites are discussed. A description of the sequence in South Wales is given and six zones are recognised. The succession in the north of France is closely comparable with that in South Wales. The relative abundance of the various genera is different, possibly indicating somewhat different conditions of deposition. The sequence in North Staffordshire is also discussed. It is concluded that the lamellibranchs afford a reliable basis for the correlation of the Coal Measures, and especially of that part of the Coal Measures which contains the more important seams.—**L. Merson Davies**: The Ranikot beds of Thal (North-West Frontier Provinces of India). Ranikot beds have never before been known to exist in India outside a very limited area in Sind; the new exposures are at Thal, on the Afghan frontier, more than 500 miles north of any hitherto known of the kind. Many new species, mostly corals, are found in the Thal beds. A particular examination has been made of the foraminifera of the Thal beds. The age of the Ranikot series is pre-Ypresian. The Upper Ranikot may be correlated with the Middle Landenian of Europe, and the Lower Ranikot with the Lowest Landenian and Montian.

DUBLIN.

Royal Dublin Society, November 23.—**H. H. Dixon** and **T. A. Bennet-Clark**: The electrical stimulation of plant tissues. The passage of an electrical current through a tissue leads to a change in electrical resistance and to a change in permeability. The stimulating current used was a sine-wave single-phase alternating current of 50 cycles, of which the voltage was controlled by a potentiometer, and the duration of the stimulus by a pendulum device. Pieces of ivy (*Hedera helix*) leaf, cut 1 cm. square, were used and were found to maintain a nearly constant resistance in the apparatus for so long as three days. A moderate stimulus (say 120 volts for 0·1 sec.) is immediately followed by a very rapid fall in resistance, which becomes less and less rapid, and, after a few minutes, the resistance rises a little and falls again. Finally, it starts to rise slowly, recovering in about an hour to the value it originally had before stimulation. Both a positive and negative deviation of resistance is initiated by the stimulus: their relative magnitudes depend on the magnitude of the stimulus. The smallest possible current causes a response if a certain minimal potential across the membrane is exceeded, and as the stimuli are increased, at first the positive reactions increase the more rapidly and predominate over the negative; with still larger stimuli the negative reactions predominate to an increasingly great extent over the positive reactions, which finally become unnoticeable after very large stimuli. The positive reactions only predominate within a small range of intensities of stimulus, and also only when the energy content of the stimulus is less than 0·01 joule under the conditions of these experiments. With stimuli all of the same energy content, the higher the intensity at which this energy is supplied the more effective it is. The relation between the intensity and the response is S-shaped. In consequence of this it is suggested that a given quantity of energy produces in any cell a definite alteration of resistance whatever the voltage at which it is supplied. It is supposed that the ability of a current to stimulate a cell is determined by the potential difference across the membranes of one cell. A series of stimuli to a single leaf square gives the same response as a single one of the combined duration of the series, provided that the intervals are not too long. We could not detect any conduction of the stimulus from the stimulated zone to any other region of the leaf. Advance of the season and also rise of temperature greatly increased the sensitivity of the tissues; the positive and negative reactions were not affected to the same extent.—**H. P. Lewis**: *Caninia cylindrica* Scouler and other large Caninias from the carboniferous limestone of Ireland.

Royal Irish Academy, November 30.—**J. J. Nolan** and **G. P. de Sachy**: Atmospheric ionisation. The conditions of equilibrium between small ions, nuclei, and large ions in the atmosphere are investigated. It is shown that, when positive and negative large ions are present in equal numbers, the ratio of the concentration of the small ions of the two signs is connected with the ratio of their mobilities by the equation $n_+/n_- = (k_-/k_+)^m$, where m is not far from unity and possibly $= \frac{3}{4}$. For n_+/n_- in atmospheric air the value 1·24 is found. In room air $n_+/n_- = 1{\cdot}11$ and $k_-/k_+ = 1{\cdot}16$. The value of the recombination constants of small ions, positive and negative, with large ions and nuclei are determined. It is found that both small and large atmospheric ions may be resolved into a number of distinct groups.

EDINBURGH.

Royal Society of Edinburgh, December 6.—**H. Graham Cannon** and **Miss S. M. Manton**: On the feeding mechanism of a mysid crustacean (*Hemimysis Lamornae*). This organism feeds on large food masses and on minute suspended particles filtered from the surrounding water. The food stream is produced by the rotary swimming movements of the exopodite of the trunk limbs, aided by a paddle-like action of the maxillary exite. The suspended particles are filtered off by the proximal endite of the maxilla and pushed into the mouth by the combined action of maxillules, maxillæ, and the proximal endite of the first trunk limb. Large food masses are held by the mandibular palps and bitten into by both the incisor processes of the mandibles and by the distal endites of the maxillules. Storch's view that the primitive feeding mechanism of the Crustacea is a filter-feeding process is criticised, and an alternative hypothesis that it resulted from the paddling activities of primitive biramous appendages is put forward.—**J. H. Awbery** and **Ezer Griffiths**: Further experiments with the Ewing ball-and-tube flowmeter. This instrument measures the rate of flow of liquid or gas by the height to which a sphere is carried up a conical glass tube. The results of varying the liquid, the size of the sphere, and the inclination of the meter, have been investigated, and the observations are grouped together by making use of the theory of similitude. There is apparently no simple method of calibrating the instrument for one liquid from the results obtained with another.—**E. A. Baker**: The law of blackening of the photographic plate at low densities. (Second Paper.) iv.—Results for isochromatic and blue-sensitive plates and filtered light. Further low density results are given, and explained on the assumption that the formation of the latent image takes place in two stages, the first being reversible, with the further assumptions that the number of absorbers in a grain is small, and that they are of at least two kinds.—**Frederick Walker**: The igneous geology of Ardsheal Hill. The summit of Ardsheal Hill is an igneous complex formed of a number of rock types of varied composition. The four principal types are kentallenite, appinite, granophyre, and hornblende-porphyrite. In common with other neighbouring intrusions, this complex is probably of Lower Devonian age.

PARIS.

Academy of Sciences, Nov. 29.—**Emile Borel**: A theorem on the linear forms with a symmetrical skew determinant.—**H. Andoyer**: The method of Delaunay.—**Georges Perrier**: The parallel of Meknès (triangulation and levelling).—**P. Villard**: The utilisation of the energy of naturally occurring warm water. Remarks on the subject of the note by G. Claude and P. Boucherot. The energy of hot springs could be more easily utilised in the manner suggested by G. Claude and P. Boucherot than that derived from tropical seas.—**F. Widal** and **M. Laudat**: Study of the modifications brought about in the nitrogen formula of blood serum by renal impermeability. Study of the distribution of the nitrogen compounds in a case of Bright's disease.—**Georges Claude**: The utilisation of the thermal energy of the sea. In January 1923 Tito Romagnoli published a paper on the utilisation of the thermal energy of the deep Italian lakes which to some extent anticipates the recent communication by the author on the same subject. Campbell in 1913 also made similar suggestions.—**G. Sauvageau**: Remarks on a note by Chemin and Legendre on the existence of free iodine in *Falkenbergia Doubletii*. Reply to criticism.—**Krawtchouk**: The distribution of prime numbers.—**Enea Bortolotti**: The angle of two conjugated directions.—**René Garnier**: Plateau's problem.—**V. Smirnoff**: The series of polynomials.—**André Roussel**: The extremum of certain double integrals.—**Podtiaguine**: The theory of growth [of functions].—**H. Galbrun**: Sound waves and zones of silence in the atmosphere.—**Paul Stroobant**: The movement of the whole of the helium stars.—**L. d'Azambuja**. The structure of the solar chromosphere.—**Jarry-Desloges**: Contribution to the study of the planet Mars. During 1926, Mars underwent important superficial modifications, greater than any observed during the preceding twenty years. Details of the observed changes are given.—**Robert Lévi**: The atom in the theory of universal and discontinuous action.—**C. Ledoux**: Method and apparatus for rapidly calculating the point in radiogoniometry.—**Mlle. Paule Collet**: Paramagnetism independent of temperature. Solid potassium permanganate, after purification by numerous recrystallisations, has a paramagnetism independent of the temperature, and this is the same as the salt in solution within the limits of experimental error. This salt forms a third example not in agreement with the law of Curie.—**A. Danjon**: The interferential study of scintillation and the conditions of stability of telescopic images. The diameters of stellar images take, under the effect of atmospheric agitation, values which are independent of the aperture of the objective when the latter exceeds 1 metre. Lord Rayleigh's rule applies to the deformation of images produced by scintillation.—**C. Mihul**: The structure of the third order of spectrum of oxygen.—**D. K. Yovanovitch** and **Mlle. A. Dorabialska**: The calorific effect of the β and γ-rays of radiothorium.—**Mme. E. Tiegler-Soru**: The ultraviolet spectrum of potassium nitrate and its variations as a function of the *p*H.—**E. Raguin**: The tectonic situation of the marbles of flaky structure near the Col de la Leysse (Savoy).—**Yves Milon**: The presence of glaucon in the Vindobonian shell marls of Brittany.—**L. Joleaud**: The tectonic of the Carib regions of South-American Columbia.—**N. Menchikoff**: Geological observations made in the course of the expedition of Prince Kemal-el-Dine Hussein in the Lybian desert (1925–1926).—**L. Blaringhem**: The segregation in mosaic of the fertile hybrids of wheat and barley.—**Jules Amar**: Oxygen-carbon dioxide antagonism. The antagonism of the two principal gases of the blood, oxygen and carbon dioxide, normally conditions the respiratory working. By increasing the proportion of either gas a mechanism of defence can be set up against intoxication by breathlessness, over-fatigue, stuffy atmosphere, and it is a method of treatment of respiratory syncope.—**J. G. Szuman**: The influence of the testicle on metabolism in the Gallinaceae.—**Mme. L. Randoin** and **Mlle. A. Michaux**: Comparative variations in the content of the suprarenal capsules in water, fatty acids, and cholesterol in the normal guinea-pig and in the guinea-pig submitted to a diet minus the antiscorbutic vitamin. The most marked change in the suprarenal capsules of guinea-pigs with experimental scurvy is the continuous fall in the proportion of cholesterol present. The proportion of fatty acids falls at first, but afterwards regains the normal. The water remains constant.—**J. Benoit**: The histophysiological study of the testicular nodules of regeneration in the domestic cock.—**Gilbert Ranson**: The resistance of young *Gryphoea angulata* to heat and their exceptional mortality in 1926.—**Emile André** and **Henri Canal**: The oil of *Mesoplodon bidens*. This oil resembles cachalot oil and oil of *Hyperoodon rostratus*. These three oils form a chemically homogenous group, the composition of which constitutes a marked physiological character of survivors of a fauna now extinct.—**Georges Truffaut** and **N. Bezssonoff**: The conditions which allow of co-operation between nitrogen-fixing bacteria and maize.

ROME.

Royal National Academy of the Lincei, Nov. 7.—**G. Armellini**: The difference between the visual magnitude and the bolometric magnitude of stars in relation to the absolute temperature.—**L. Herrera**: Appearances of struggle and of parasitism with simulations of infusoria. The name "colpoids" is suggested for the infusoria-like preparations made from soap solution and a solution of olive oil in petrol. These colpoids are spherical, elliptical, or of irregular and often ameboid form. Their dimensions vary from 100 to 800 microns or even more, and many of them are visible to the naked eye. Certain of the phenomena accompanying their mutual encounters exhibit very close resemblance to those observed with the struggling and parasitism of living infusoria.—**Alessandro Terracini**: Characterisation of Bianchi's systems of ∞' surfaces.—**E. Raimondi**: Approximate calculation of the dynamic effect of a current flowing between a lamina and an indefinite plane wall.—**Arnaldo Masotti**: Uniform translation of a circular cylinder in a channel with plane parallel edges.—**U. Barbieri**: Astronomical determination of latitude computed at Mondovi in 1925.—**Bianca Nannei**: Cycles of elastic hysteresis in bismuth wires. The cycles followed by the elastic behaviour of steel and iron wires are due principally to a hereditary elastic effect which is gradually dissipated, whereas with bismuth wires they represent a phenomenon of permanent deformation, also distinctly hereditary in character.—**Umberto Crudeli**: Electromagnetic fields having the electric (magnetic) field zero at the circumference and the magnetic (electric) field tangential at the circumference.—**M. Philibert**: Further observations on the apparent duplication of the optic axis of calcite by Federow's plate. This duplication is only apparent and is caused by the anisotropy of the spherical segments of the Federow's plate, which behave like a doubly refracting biaxial substance. Far from being negligible, this double refraction of the segments gave rise to an axial angle of 14° in one case investigated.—**G. Carobbi**: New researches on noteworthy Vesuvian sublimates. Microscopic and crystallographic examination of material from the inner walls of a fumarole situated in a laval canal of the cupola formed on Vesuvius in April-May 1924 reveals the presence of boric acid in the form of sassoline and of potassium fluoborate as avogadrite.—**Guido Cusmano**: New process of dehydrogenation of menthol. When sodium is heated with menthol to about 300°, hydrogen is liberated in abundance and the mass becomes spongy, the sodium mentholate first formed losing hydrogen (2 atoms) to form a sodio-menthone, which again loses hydrogen (4 atoms) to yield sodium thymolate.—**G. Scagliarini** and **G. Tartarini**: Additive compounds of halides of bivalent metals with organic bases (iii). With cobalt and nickel chlorides and cobalt bromide, urotropine forms additive compounds of the form, $CoCl_2$, $C_6H_{12}N_4$.—**Ettore Remotti**: Photo-reactive behaviour in tadpoles and fry fed with thyroid. When tadpoles and the fry of *Salmo lacustris* and *S. irideus* are subjected to treatment with thyroid, their sera undergo important modifications in the colloidal equilibrium, these modifications being attributable partly to increased dispersion.—**Silvio Ranzi**: Investigations on the placodes of Cyclostomi, Ganoidei and Teleostei with respect particularly to the fate of the first epibranchial placode.—**Constantino Gorini**: Behaviour of *Bacterium typhi* in milk. Contrary to the opinion held up to the present, the typhus bacillus is capable of coagulating milk. The mechanism of the change is novel and peculiar and consists of an alkalifying, solubilising phase, followed by an acidifying and coagulating phase. The former phase is preceded by a transitory acidification, the conclusion drawn being that the organism is able to attack lactose, but prefers the casein, which is first proteolysed with production of bases. In the favourable medium thus created, the lactose is decomposed with development of acidity. The passage from the first to the second phase would be characterised by a process of reversion of the casein from the dissolved to the colloidal state.

SYDNEY.

Linnean Society of New South Wales, Oct. 27.—**J. R. Malloch**: Notes on Australian Diptera (ix).—Two genera and ten species are described as new in the families Ephydridæ, Agromyzidæ, Ortalidæ, Sapromyzidæ, Helomyzidæ, Neottiophilidæ and Muscidæ, the new genera belonging to Ortalidæ and Muscidæ.—**Lucy M. Wood**: On some land planarians from Barrington Tops, N.S.W., with descriptions of new species. The collection described comprises six species, representing the three genera Geoplana, Artioposthia and Platydemus, four of the species being regarded as new.—**E. W. Ferguson**: Revision of Australian Syrphidæ (Diptera). Part ii. Subfamily Milesiinæ. Five genera (1 new) and 21 species (10 new) are described. Four species of Graptomyza (subfamily Volucellinæ) are also described, three of them being new.

VIENNA.

Academy of Science, November 18.—**L. Moser** and **A. Brukl**: Determination and separation of the rare metals from other metals (viii.). Determination of thallium as thallium chromate and its separation from other elements. Sulphosalicylic acid is used to separate some metals, potassium cyanide and sodium thiosulphate separate others.—**A. Winkler**: Geological studies in the tertiary region of south-west Styria. Conglomerates and delta deposits.—**R. Seka** and **O. Schmidt**: Amino-derivatives of dinaphthanthracene-diquinone.—**O. Kuhn**: A new hydrozoon from the Jura of Stramberg.—**L. Waldmann**: The geological structure of the Moldau-Danubian primitive rocks on the map sheet Gmünd.—**H. Kupper**: The facies relations of the newer palæozoic in Carinthia. Limestones and the Carboniferous.—**E. Jahoda**: Luminescence and coloration of alkali chlorides when treated with Becquerel rays. A red fluorescence was due to the presence of manganese.

Official Publications Received.

BRITISH AND COLONIAL.

Catalogue of B.D.H. Fine Chemical Products, including Organic and Inorganic Chemicals, Analytical Reagents, Indicators, Standard Stains. Pp. 108. (London: The British Drug Houses, Ltd.)

Diary of Societies.

SATURDAY, JANUARY 15.

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (at Neville Hall, Newcastle-upon-Tyne), at 3.—J. S. Carson: Dry Cleaning of Coal.—Paper by L. F. H. Booth, Screening and Washing Plant at Deaf Hill Colliery, open for further discussion.

INSTITUTE OF BRITISH FOUNDRYMEN (Lancashire Branch, Junior Section) (at Manchester College of Technology), at 7.—W. Jolley: My Impressions of American Foundries.

MONDAY, JANUARY 17.

CAMBRIDGE PHILOSOPHICAL SOCIETY (at School of Agriculture, Cambridge), at 4.30.—Prof. T. B. Wood: Animal Calorimetry.

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4.30.—G. B. Michell: The Comparative Chronology of Ancient Nations in its Bearing on Holy Scripture.

ROYAL GEOGRAPHICAL SOCIETY (at Lowther Lodge, Kensington Gore), at 5.—G. S. Laird-Clowes: Ships of Early Explorers.

INSTITUTION OF ELECTRICAL ENGINEERS (North-Eastern Circle) (at Armstrong College, Newcastle-upon-Tyne), at 7.—Prof. W. M. Thornton: What is Electricity? (Faraday Lecture).

INSTITUTION OF ELECTRICAL ENGINEERS (Tees-Side Sub-Centre) (at Cleveland Technical Institute, Middlesbrough), at 7.—L. C. Grant: Wired Wireless.

INSTITUTION OF AUTOMOBILE ENGINEERS (Scottish Centre) (at Royal Technical College, Glasgow), at 7.30.—A. N. May: Electric Lighting for Public Service Vehicles.

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.—Award of Prizes and Studentships.

ROYAL SOCIETY OF ARTS, at 8.—Dr. L. C. Martin: Recent Progress in Optics (Cantor Lectures) (1).

HUNTERIAN SOCIETY (at Mansion House), at 9.—Dr. J. M. T. Finney: The Influence of John Hunter on American Surgery.

ROYAL SOCIETY OF MEDICINE (Social Evening), at 9.30.—Prof. A. W. Sheen: Medicine in Ancient Greece.

CHEMICAL INDUSTRY CLUB.

TUESDAY, JANUARY 18.

SOCIETY OF GLASS TECHNOLOGY (at Manchester College of Technology), at 2.30.—Prof. W. E. S. Turner: The Effect of Cullet on the Melting of Glass.—Prof. J. F. Ponomareff: Investigation of the Glassy State by the Method of Forced Crystallisation.—Violet Dimbleby and Prof. W. E. S. Turner: The Durability of Some Soda-Lime Magnesia Glasses.—Prof. W. E. S. Turner and F. Winks: The Thermal Expansions of Some Boric Oxide Containing Glasses.

Royal Institution of Great Britain, at 5.15.—Prof. R. Whytlaw Gray: Smokes as Aerial Disperse Systems (1).

Royal Statistical Society (at Royal Society of Arts), at 5.15.—A. W. Flux: Indices of Industrial Productive Activity.

Mineralogical Society, at 5.30.—Dr. A. Brammall and Dr. H. F. Harwood: The Temperature-range of Formation for Tourmaline, Rutile, Brookite, and Anatase in the Dartmoor Granite.—A. Russell: Notice of an Occurrence of Niccolite and Ullmannite at the Settlingstones Mine, Fourstones, Northumberland, of Stichtite at the Island of Unst, Shetlands; and Serpierite at Ross Island Mine, Killarney, Co. Kerry, Ireland.

Royal Society of Medicine, at 5.30.—General Meeting.

Institution of Electrical Engineers (East Midland Sub-Centre) (at Derby Technical College), at 6.45.—B. M. Chamney: Telephonic Repeaters.

Royal Photographic Society of Great Britain (Kinematograph Group), at 7.—J. B. Pryde-Hughes: The Land of the Magyar.

Hull Chemical and Engineering Society (at Grey Street, Hull), at 7.45.—H. W. C. Henderson: The Lodge-Cottrell Electrical Precipitation Process.

WEDNESDAY, January 19.

Society of Glass Technology (at Grand Hotel, Manchester), at 2.30.—Prof. W. E. S. Turner: The Present Position of the Glass Industry in Germany.—Prof. J. F. Ponomareff: Developments in the Glass Industry in Russia.

Royal Society of Medicine (History of Medicine Section), at 5.—Dr. A. Currie: The Medical History of the First Three Wives of Henry VIII. and their Offspring.—W. R. Dawson: Contributions to the History of Mummification.

Geological Society of London, at 5.30.—L. J. Chubb: The Geology of the Austral or Tubuai Islands (Southern Pacific).—W. Campbell Smith and L. J. Chubb: The Petrology of the Austral or Tubuai Islands (Southern Pacific).

Institution of Civil Engineers, at 6.30.—H. R. J. Burstall: The Testing of Heat Engines.

Institution of Automobile Engineers (Informal Meeting) (at Junior Institution of Engineers), at 7.—Cinema Films of Engineering Interest.

Institution of Electrical Engineers (South Midland Centre) (at Birmingham University), at 7.—A. R. Cooper: Electrical Equipment of Track on the Underground Railways of London.

Institution of Electrical Engineers (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7.30.—H. B. Yerbury and others: Informal Discussion on The Electricity Bill.

Merseyside Aquarium Society (at 1 Falkland Road, Egremont), at 7.30.—Dr. J. Cotton: Aquatic Insects.

Royal Meteorological Society (Annual General Meeting), at 7.40.—Presentation of Buchan Prize to C. K. M. Douglas.—Sir Gilbert T. Walker: The Atlantic Ocean (Address).

Royal Microscopical Society (Annual Meeting), at 8.—Dr. J. A. Murray: Nuclear Degeneration due to Multipolar Mitosis (Presidential Address).

Royal Society of Arts, at 8.—Sir John Cadman: Development of the Petroleum Industry in Persia.

Folk-Lore Society (at University College), at 8.—Miss Canziani: Folklore of the Abruzzi.

Electroplaters' and Depositors' Technical Society (at Northampton Polytechnic Institute), at 8.15.—H. Sutton: Electrodeposited Coatings for Prevention of Corrosion.

Royal Society of Medicine (Surgery Section), at 8.30.—Dr. J. M. T. Finney: Some Considerations Concerning the Pathology and Treatment of Gastric and Duodenal Ulcers.

Institute of Chemistry (London Section).

THURSDAY, January 20.

Royal Society, at 4.30.—A. Egerton and S. F. Gates: On Detonation of Gaseous Mixtures of Acetylene and of Pentane.—J. Topping and Prof. S. Chapman: On the Form and Energy of Crystalline Sodium Nitrate.—J. Topping: On the Mutual Potential Energy of a Plane Network of Doublets.—W. H. George and H. E. Beckett: The Energy of the Struck String.—*To be read in title only*:—S. R. Milner: An Analysis of the Electro-magnetic Field into Moving Elements.—D. Buchanan: Periodic Orbits of the Second Genus near the Straight-Line Equilibrium Points in the Problem of Three Bodies.—Prof. E. C. C. Baly, R. A. Morton, and R. W. Riding: The Measurement of Absorptive Power.—R. A. Morton and R. W. Riding: Absorption Spectra of Nitrates in the Region 300 μμ.—J. S. Foster: Observed Stark Patterns in Helium.—J. E. Lennard-Jones and B. M. Dent: Some Theoretical Determinations of the Structure of Carbonate Crystals.—Prof. H. T. Barnes: Some Physical Properties of Icebergs: and a Method for their Destruction.—Prof. J. W. McBain and W. B. Lee: Adhesives and Adhesions: True Chemical Compounds as Adhesives.—Prof W. L. Bragg: The Structure of Phenacite, Be_2SiO_4.—H. H. Potter: On the Proportionality of Mass and Weight.—D. M. Y. Sommerville: The Relations connecting the Angle-Sums and Volume of a Polytope of n Dimensions.—P. A. M. Dirac: The Physical Interpretation of the Quantum Dynamics.—Prof. H. M. Macdonald: The Intensity of the Radiation from a Source of Electric Waves, when the Electric Constants of the Medium in the Neighbourhood of the Source are Different from the Electric Constants at a Distance from it.

Royal Institution of Great Britain, at 5.15.—J. R. H. Weaver: Romanesque and Early Pointed Architecture in Spain (1).

Institution of Mining and Metallurgy (at Geological Society), at 5.30.

Institution of Electrical Engineers, at 6.—G. Dunsheath: 33,000-Volt Cables with Metal-sheathed Cores, with special reference to the S.L. Type.

Institution of Automobile Engineers (Graduates' Meeting) (at Watergate House, Adelphi), at 7.30.—J. N. H. Tait: Mixture Distribution in Multi-cylinder Petrol Engines.

Institute of Chemistry (Edinburgh and East of Scotland Section) (jointly with Society of Chemical Industry, Edinburgh and East of Scotland Section) (at 36 York Place, Edinburgh), at 7.30.—Dr. C. H. Lander: The Importance of Fuel Research in the Coal Problem.

Institution of Civil Engineers (Yorkshire Association) (at Hotel Metropole, Leeds), at 7.30.—J. Clemmshaw: The Construction of Sewers in Tunnel.

Chemical Society, at 8.—H. J. Emeléus: The Glow of Arsenic.—H. J. Emeléus and R. H. Purcell: On the Origin of the Spectrum of the Glow of Phosphorus.

Royal Society of Tropical Medicine and Hygiene (at 11 Chandos Street, Cavendish Square), at 8.15.—Prof. J. W. W. Stephens: The Hæmoglobinurias.

Abernethian Society (at St Bartholomew's Hospital).—Prof. W. Blair Bell: Team Work in Research, with Special Reference to the Nature and Treatment of Cancer.

Institution of Mechanical Engineers (Manchester Branch) (at Manchester).—G. Arrowsmith: Steam Turbines.

FRIDAY, January 21.

Royal Society of Medicine (Balneology and Climatology Sections), at 4.—Dr. L. J. Llewellyn and others: Discussion on Climacteric Arthritis.

Royal Society of Arts (Indian Meeting), at 4.30.—H. A. F. Lindsay: Recent Developments in Indian Trade.

Society of Chemical Industry (Liverpool Section) (at Liverpool University), at 6.—Prof. W. C. McC. Lewis: Some Physico-Chemical and Bio-Chemical Aspects of Malignant Growths.

Junior Institution of Engineers, at 6.—Exhibition of Scientific Instruments and Apparatus.

Institution of Mechanical Engineers, at 6.—Prof. A. L. Mellanby and Prof. W. Kerr: Use and Economy of High Pressures in Steam Plant.

Institution of Electrical Engineers (London Students' Section), at 6.15.—H. B. Watton: Automatic Voltage Regulators.

Society of Chemical Industry (Glasgow Section, jointly with Institute of Chemistry) (at 39 Elmbank Crescent, Glasgow), at 7.—J. W. Donaldson: The Volatility and Carbonisation of Oils for Cylinder Lubrication.

Royal Photographic Society of Great Britain (Pictorial Group), at 7.—The Pictorial Aspects of the Lantern Slide.

Geologists' Association (at University College), at 7.30.—Dr. W. G. Shannon: Petrography and Correlation of the Sedimentary Rocks of the Torquay Promontory. Section II.—Permian Rocks.—H. A. Merrett: The Geology of the Lower Valley of the Gade.—W. F. Fleet: The Heavy Minerals of the Keele, Enville, 'Permian' and Lower Triassic Rocks of the Midlands, and the Correlation of these Strata.

Royal Society of Medicine (Obstetrical Section) (jointly with Medico-Legal Society) (at 1 Wimpole Street, W.), at 8.—Dr. J. S. Fairbairn, Lord Riddell, Dr. T. W. Eden, and Sir Travers Humphreys: Discussion on The Ethical, Legal, and Medical Aspects of Abortion.

Royal Society of Medicine (Electro-Therapeutics Section), at 8.30.—Sir Henry Gauvain and others: Discussion on Light Treatment in Surgical Tuberculosis.

Royal Institution of Great Britain, at 9.—Sir William Bragg: Tyndall's Experiments on Magne-Crystallic Action.

Society of Dyers and Colourists (Manchester Section) (at Manchester).—R. S. Horsfall: Modern Industrial Chemistry.

SATURDAY, January 22.

Royal Institution of Great Britain, at 3.—Prof. E. W. Tristram: English Medieval Wall-Painting.

Physiological Society (at National Institute for Medical Research).

PUBLIC LECTURES.

SUNDAY, January 16.

Guildhouse (Eccleston Square), at 3.30.—G. A. de Zoysa: The Soul of Buddhism.

TUESDAY, January 18.

Bedford College for Women, at 5.15.—Dr. R. Campbell Thompson: Conceptions of the Cosmos in Ancient Babylonia.

University College, at 5.30.—Dr. E. G. Richardson: Acoustics of Buildings. (Succeeding Lectures on January 25 and February 1.)

Gresham College, at 6.—A. R. Hicks: The Total Eclipse of the Sun in June in Northern England. (Succeeding Lectures on January 19, 20, and 21.)

WEDNESDAY, January 19.

Institute of Historical Research (University College), at 5.30.—N. B. Jopson: The Prehistoric Relations of the Slavs with their Neighbours. (Succeeding Lecture on January 26.)

University College, at 5.30.—Dr. A. Kihlbom: Modern Sweden: the Land and the People. (Succeeding Lectures on January 26 and February 2.)—Major C. Davenport: The Origin of the Book.

THURSDAY, January 20.

University College, at 5.—Dr. D. T. Harris: The Biological Action of Light. (Succeeding Lectures on January 27 and February 3.)

King's College, at 5.30.—Prof. R. J. S. McDowall: The Mind Physiology.

Northampton Polytechnic Institute, at 7.—R. Genders: Steel and its Thermal Treatment: The Carbon Steels.

SATURDAY, January 22.

Horniman Museum (Forest Hill), at 3.30.—Mrs. H. M. Dunn: Benares, the Sacred City.

SUNDAY, January 23.

Guildhouse (Eccleston Square), at 3.30.—S. N. Mallik: Hinduism.

CONFERENCE.

January 19.

Rothamsted Experimental Station, at 11.30 A.M.—The Culture and Manuring of Sugar Beet:—J. M. Van Bommel Van Vloten: Continental Experience with the Growth of Sugar Beet.—T. G. Fowler: What the Factory wants and how the Farmer can supply it.—L. J. Schapringer: Effect of Climate on the Cultivation of Sugar Beet.—R. N. Dowling: Experiments with Sugar Beet in the Midland Counties.—C. J. Clarke: Practical Experience in South-West England.—H. J. Page and C. Heigham: Manurial Experiments with Sugar Beet at Rothamsted and Woburn.

SATURDAY, JANUARY 22, 1927.

"On the truth which Science has revealed, and is revealing, we build the new humanism of our age."—Dr. Barnes, Bishop of Birmingham.

RETURNING in 1925 from a world tour, Haber, concerned with the economic plight of Germany, her lack of raw materials, the inconsiderable increase of agricultural efficiency, delivered this message to the German people: "Man kann nämlich den Reichtum nicht nur aus dem Boden holen, sondern auch aus dem menschlichen Verstande." He declared this 'invisible item' of the national balance sheet, the trained human intelligence, to be of vital importance for the resuscitation of his country. He claimed, and rightly, that the German system of higher education has proved more effective than that of any other country in producing men of creative achievement in technical science; they are the geese which lay the golden eggs. That it has not failed in pure science is amply evidenced by the list of Nobel prizemen. He disclaimed any intelligence for his own people higher than in other countries; he attributed the success to the method by which the intelligence has been trained and then utilised, France being inferior in the higher education, England lacking co-operation between university and industry, America being deficient in depth and patience though replete with cash and equipment.

How, indeed, is it with us? In the ten years preceding the War we had made rapid strides in secondary and university education, during the War we envisaged still greater progress, but we chose the policy of the 'knock-out blow' and must wait for the fabric of the vision. Just seven years have slipped away since the Peace Treaty was signed, and we do not yet know whether our ship is slowly sinking or will right herself. Our cousins, over yonder, say we are 'down and out.' They relish exaggeration; yet who can study the events of 1926 and remain blind to the threat that Britain's days as the workshop of the world are numbered? The coal and iron and engineering genius, which together with our coast-line placed us far in the van of industrial development, can keep us there no longer, but our industrial population remains. Trained intellect alone can enable us to hold our own until the transformation of our social organisation shall have been accomplished without catastrophe. Trained intellect—not only, nor even chiefly, trained in technical science. It is true that science furnishes the key to Nature's storehouse of power, that the trained intellect has made man a creator, but of even greater importance is the use he makes of the power and the kind of life he creates. Science is determining the material conditions; the new humanism must rise to the occasion and teach us how to live. Creative thought is what the world is needing in all departments of life; it will express itself in literature and other arts, and it will issue in new hope and energy in all ranks of society. The destiny of Great Britain, and even its immediate future, hang upon the success we can achieve in leading the right men to devote their lives to science, in supplying the needs for their work, and in permeating the nation with a sense of responsibility that the gifts of science shall not be misused.

Great Britain has indeed been exporting much of its 'invisible item' for many years to India and other parts of the globe, carrying the white man's burden. There are obvious signs that this export, like others, will diminish in the near future—no other country has suffered such a drain—and with this leak stopped, the home level may be expected to rise.

No one can doubt that the talent is there. Does any one claim that we make the most of it? The practical problem is beset with difficulties, complexities, incompatibilities. There is no single simple solution possessing all the virtues and omitting none; and time is precious. Ought boys to leave school and approach their university studies fresher in mind? Is too early specialisation in schools a cause of sterility later; and when is *too* early? Is our conception of the university as a sort of examination mill wholly mistaken, if not immoral, and the German plan wholly right, with its freedom from mark-grubbing, and only a *viva voce* on subjects subsidiary to a thesis? And if not absolutely ideal, is it not at any rate more effective in developing the right man and discouraging the rest? The fact is that we are even now engaged on a new synthesis in education, one which bids fair to spare the wheat and straw the chaff. Our national genius is not logical but practical—logic thrives on narrow premises. We have succeeded in producing a multiplicity of types of schools and universities, and rightly used this multiplicity will ease the problem; it may go far to solve it.

The time between educational seed-time and harvest is long, but intensive culture in the last years at school and during the university period may bring forth fruit in a few years. Further, school and university interact rapidly; the effect is like that of the 'reaction' on a radio receiving set, and if judiciously applied the result is harmonious 'amplification,' for the man fresh from the university brings new life back to the schools. Unfortunately, at present the effect of the university on some of the most promising boys is as though the coils were wrongly connected; we get not amplification but *damping*. Many a teacher, not alone the science master, knowing the keenness and capacity of his most brilliant scholars, has felt sick at heart as he noted the effect upon these boys of the enforced repetition of work done years before at school.

The universities do their best to deal with the heterogeneous crowd that presents itself, but the lecturers are frequently overworked and underpaid and are possibly not adequately aware of the thoroughness and high standard of the teaching in many schools. They wearily resist all suggestion of exemption from the first-year courses, or complain that the students are packed with much knowledge but little intelligence. Ought the boys to leave school earlier? Some universities think they ought, and prefer them not to have taken the higher certificate; others regard it as equivalent to their intermediate examination and grant exemption accordingly; some accept it in lieu of the first M.B. if the appropriate subjects are taken, and the reason is a good one, for it is based on the long period of later medical courses.

Obviously the problem of the best development of a *person* is a personal matter, and whenever possible a personal solution should be sought; but schools and universities are institutions, and organisation is paramount. For the purpose of this discussion boys may be divided into the precocious clever and the slow-maturing capable. If the leaving age is eighteen or nineteen, as is usual in the best schools, both types will benefit greatly in character by the sense of responsibility developed in the last year of school life; this would not be very seriously reduced if all boys left a year earlier, for the responsibility would be the same; but if two years were cut off, the boys would not be mature enough and would lose something of great value. Going up to a university at nineteen, the clever boy finds he need not work hard in order to get a good degree, and may seize the wider social and educative opportunities of university life—he may seize them too hard if thwarted in his keenest interest, his life's work; the slower boy, faced by an examination test unsuited to his type, makes inconspicuous progress. If both boys were to go up at seventeen the slow boy would have to work harder for his degree and the clever boy would do well in his examination, but both of them would have two more years to spend at the university free from the warping strain of examinations, free to develop under guidance along lines of natural inclination and innate ability. The fact that the two boys are being compared after the degree examination means that the clever boy has as good a chance as ever of showing what is in him, and the slower maturing boy is being given his chance, at the latest possible academic period and under the most favourable conditions of concentration, to show his capacity. A third plan suggests itself. If nineteen years were adopted as the leaving age, a two-year degree course might be a possibility, ending with an examination, but followed by two more years of post-graduate training of some creative kind and a thesis.

The age at which specialisation should be allowed in schools might also be regarded as dependent on the precocity or otherwise of the boy. On the other hand, it is a matter of experience that the obvious development of the less precocious boy dates from the moment when he was allowed to specialise on a subject of his own choice. The precocious boy is quite usually, though not always, blessed with wide intellectual interests which continue throughout life, and concentration does him no harm. But something more may be required of the university than satisfaction with courses all severely scientific. All science students should be expected to attend at least one course such as philosophy, English literature, and history or economics, preferably in the post-graduate period when their minds will be free to enjoy them, and not for an examination test but for an essay. Similar courses in the sciences might prove of inestimable value for students in arts, if the right men were chosen to create them.

At present, if a student goes up to the university younger than his competitors, he risks getting a poorer degree and making a poorer impression on his teachers, and with it he reduces his chance of post-graduate opportunities. While this remains so, it is scarcely fair to leave the momentous decision to the individual; the handicap is too heavy.

One further point arises. The schools like to keep boys until nineteen years of age. The British type of university does, at least, produce science teachers whose enthusiasm and ability is a great asset to the country. Compared with German universities, where there is almost no routine teaching for degrees by examination and everything is ordered for what we treat as post-graduate work, the science staff of our universities is lamentably small, and the salaries much lower than in the schools. If the universities continue to have to provide instruction, which in Germany is done in the schools, by men who have in addition to master the mass of literature and prosecute research, they will need a corresponding increase of staff or find the task an impossibility. If the schools send their boys at seventeen, then possibly some of the science masters might return to the university with riper teaching experience than the ordinary lecturer can ever hope to acquire; but unless the university authorities cease to override the recommendation of the Treasury Grants Committee, they would do so at heavy pecuniary loss.

The introduction of the Ph.D. degree has created a new situation: the universities must make adequate arrangements for post-graduate work. The crux of the question is the relative value to a man leaving the university at twenty-two years of age, of two more years at school or two years' post-graduate work at the university. Under one system the absorptive sponge may prosper, readily yielding its secreted information under pressure of examinations, but for the development of creative thought the post-graduate years are incomparably more fertile.

The Interior of a Star.

The Internal Constitution of the Stars. By Prof. A. S. Eddington. Pp. viii + 407. (Cambridge: At the University Press, 1926.) 25s. net.

ATTEMPTS to construct theories about the physical conditions inside a star need, of course, no excuse. Such theories are on the same footing as other physical theories, inasmuch as many intermediate steps will be inaccessible to the test of observation. They have, therefore, the right to a fair and serious judgment on a par with ordinary physical theories, according to agreement with observation, inner consistency, or beauty and simplicity.

In his recent book Eddington attempts to give a complete review of current theories concerning the state of things in the stellar interior. This field of theoretical investigations was, in fact, first opened up seriously by Eddington himself not more than ten years ago; and although quite a number of investigators have entered the field since that time, still his own work predominates, and 'Eddington's theory' has become a popular abbreviation for prevailing, and sometimes conflicting, views on this subject.

The growth and development of the theory of matter under stellar conditions has, as might have been expected, run closely parallel to the growth of knowledge about atomic structure. Apart from the point stressed in Eddington's first paper on this subject, namely, that inside a star energy is primarily transferred by radiation, most recent progress in this field is directly traceable to some recent progress in atomic physics. Thus the recognition that the mean molecular weight of matter inside a star may approach a limit in the vicinity of 2 was suggested (by Newall and Jeans) as a direct consequence of the fact known from X-ray experiments that even the most strongly bound electrons may be knocked out of the atoms by suitable stimuli. Eddington's theory of 'white dwarfs' is based directly on the small dimensions of atoms in *K*- or *L*-states predicted by Bohr's theory. The theory of the stellar absorption coefficient, imperfect as it is, was based on recent measurements of X-ray absorption coefficients. When astronomical theory is still groping in the outermost darkness concerning the source of stellar energy, or the origin of the penetrating radiation discovered by Hess and Kolhörster, is it not ultimately because essential facts concerning possible transformations of matter are still out of touch with the technique of the physicists? Eddington's book gives, of course, full recognition to the dependence of astrophysics on physics, and may, just for this reason, cause grief and humiliation to the classical astronomical reader who is out of touch with the modern trend of science in this field.

The general run of the book is as follows. After a short survey of the main features of the problem, both from the observational and from the theoretical side, two chapters are devoted to basic physical theories concerning radiation, atomic structure, and the statistical theory of gaseous assemblies. The fifth and sixth chapters give a thorough discussion of the theory of hydrostatic equilibrium of gaseous stars. In the seventh chapter the theoretical formula connecting the total luminosity of a star with its mass, dimensions, and mean opacity (suitably defined) is calibrated by comparison with observations. The result is that the mean opacity is about constant for stars with the same mass, while it *does* vary for stars with different masses. The relation in question is, therefore, essentially one between luminosity and mass, the dimensions of the star being of no particular concern. The theory thus amplified is, in Chap. viii., applied to different problems concerned with variable stars. The pulsation theory of Cepheid variability is given in full, its odds and ends are looked into; and a similar theory of long-period variability is tentatively suggested.

So far, the constancy and numerical value of the opacity appearing in the mass-luminosity relation has been used as an observational fact. In Chap. x. this question is taken up from the physical point of view, and it is shown how ionisation theory, coupled with almost any reasonable radiation theory, accounts satisfactorily for the observed constancy of the opacity in stars with the same mass as well as for variation with mass. The numerical value of the opacity predicted by theory seems, however, to be decidedly smaller than the observed one, a riddle which is left unsolved by the author. In the tenth chapter several accessory problems are considered, such as the exact degree of ionisation of stellar material, the validity of perfect gas laws, distribution of different elements throughout a star, and the problem of rotation.

The discussion of the delicate question of the source of stellar energy is reserved for the last chapter in the series. There is no doubt that this problem is one of the most urgent in modern astronomy. It seems, however, that we still are remote from an adequate solution, and the author has therefore concentrated his attention on a thorough and open-minded discussion of suggested possibilities, and has not endorsed any hypothesis in particular. This chapter closes the book, as defined by its title. Two chapters on allied subjects are, however, added, one on the theory of stellar spectra, and the other on the state of matter in interstellar space.

The book will doubtless be heartily received, not only by astronomers, but also by physicists as well, many of whom are deeply interested in astronomical problems. It is stimulating reading; not only where one agrees, but also where one does not agree with Eddington. I feel myself in opposition as regards quite a number of (minor) points. Take, for example, the chapter on quantum theory. Here the requirement of reversibility of physical processes in a state of thermal equilibrium, which was established long before the advent of quantum conceptions, is raised to the rank of *Law I.* of quantum theory. In the same chapter a hardy attempt is made, on the basis of this Law I., to construct a new statistical technique, which evidently is intended to supersede ordinary statistical mechanics. Without passing any judgment as regards the failure or not of this attempt, I should much have preferred the use of ordinary statistics in a book intended for the general reader. The statement in § 193 that radiation pressure acts primarily on atoms, not free electrons, seems to me to need further elucidation, especially in view of the statement made in § 147, that "there can be little doubt that the principal process of absorption in the stars is the photo-electric effect." There are other places, too, where I doubt if the statements are adequate to the facts. Further, I have the impression that the book might have been easier and more straightforward reading if less attention were given to theories which might better have been left to a merciful oblivion.

It is no use, however, to dally long over such questions. The book is undoubtedly destined to exercise a great and healthy influence on the scientific activity in this field; and nobody who reads it can fail to feel a deep admiration for the extraordinary flexibility of mind of its author, for his power of going to the root of difficult questions of the most diversified kinds, and for his remarkable ability of expounding his results in intelligible language.

SVEIN ROSSELAND.

The Life of a Nilotic Tribe.

Die Schilluk: Geschichte, Religion und Leben eines Niloten-Stammes. Nach P. Banholzers F.S.C. und eigenen Auszeichnungen dargestellt. Von Wilhelm Hofmayr. (*Anthropos*, Ethnologische Bibliothek: Internationale Sammlung ethnologischen Monographien, Band 2, Heft 5.) Pp. xvi + 521 + 35 Tafeln. (Mödling bei Wien: Verlag der Administration des *Anthropos*, St. Gabriel, 1925.) 20 gold marks.

FATHER HOFMAYR has produced the first monograph on a tribe of the Anglo-Egyptian Sudan, and is therefore to be congratulated. Yet, grateful as ethnologists must be for this volume, the author has distinctly lessened the value of his monograph by limiting the material he has used. So far as the Shilluk themselves are concerned, he seems to have depended for the bulk of his material on the unfinished notes in the journal of the late Father Banholzer; it is true that he has supplemented these by a number of his own observations made between the years 1906 and 1916, as well as those of two other missionaries, Fathers Kohnen and Stang, and added some useful comparative material collected by Father Crazzlara among the Acholi, but he has not availed himself of the material which has appeared during the last few years in *Sudan Notes and Records*; indeed, the reviewer has not noticed any reference to this most useful periodical. These remarks are made in no carping spirit, but are necessary, for in an important work such as this it is advisable that the reader should realise the extent to which omissions are probable. There is no index; only a table of contents.

This said, there can be little but praise for the work. The book is divided into four main parts, the first of which deals with the early wanderings of the ruling stock, and ends with their settlement in their present land under Nyakang—the founder of the Shilluk nation and the first king. Here the most important fact that is brought out is the former existence of a Jur-Shilluk tribe, the people of Dimo, who remained as Jur in their present country, while the adherents of his father's half-brother, Nyakang, followed the latter in his migration. The second part might be called the Book of Royalty, since it treats of the dynasty founded by Nyakang, gives a genealogy of the royal family, examines the reign and chief doings of each king, describes the life of a king from birth, through youth, adolescence, maturity, to death and burial, and ends with a short account of the court language, *i.e.* the vocabulary, not a very copious one, applied especially to the king and his doings. A number of tables of succession are given, three collected by Europeans and four derived from natives; that accepted differs from those previously collected by Banholzer, C. G. Seligman, and Westermann. Chal is given as son and immediate successor of Nyakang, while a queen, Abudok, daughter of Boc (Bwotch), is admitted to the list of reigning sovereigns. This queen was unpopular, her judgment and awards being doubted on account of her sex, and her manner of death is unknown. There are other minor differences, and, considering the authority of Father Hofmayr's native informants, it seems that the list he compiles (p. 42) should be regarded as authoritative and be accepted in future, while the 'queens' of whom the writer heard vaguely in the south can be accounted for as the princesses referred to as chiefs (p. 71). History is considered to begin with the fifth king, Ochalo (Ocwolo), about 1600, but no evidence is adduced for this date, which gives an average of about thirteen years for each reign.

The life and activity of the Shilluk king is dealt with at length, many fresh details being given, but nothing that substantially contradicts earlier accounts. Thus the suggestion put forward by Seligman that the folklore account of the king having at one time to fight for his life actually refers to a former condition is supported by the sham fight, theoretically the first indication of his election, between the king-elect and one of the four 'high chiefs' of the Shilluk country. At Debalo, the first village that the king-elect enters ceremonially, three fires—kindled by friction—are made in front of a large hut which is specially built for the occasion and where the king-elect should spend a month. One of these fires becomes the life-token fire of the new king, and a brand therefrom is carried to the capital—Fashoda. The description of the royal entry into the capital differs but little from that of previous authors. Father Hofmayr, however, has recorded an interesting addition; the king treads on an old man laid bound on the ground for the purpose. According to an account given to the reviewer in 1921, this was substantially a human sacrifice, for the old man was covered with flour paste, and was so betrodden by the multitude that he was expected to die.

The king passes three days in a special hut, and then on the fourth day is carried by the Ororo to Aturwic, his home on the built-up mound at Fashoda; here a further period is spent in retirement. After this the king is for the first time acknowledged throughout the nation. On his first leaving the mound the king is engaged in a sham fight, in which he vanquishes his opponent, and the ceremony is brought to an end with a sacrifice. The chiefs make oration on the rights and duties of the ruler, emphasising their points by brandishing their spears and thrusting them into the ground. The king promises to be a just ruler, to punish wrong, and to protect the weak, and then dismisses the people with an exhortation to remain true to Nyakang and the ancient customs.

A new fact with regard to the king's part in the rain ceremony is that as a last resource, after repeated failure, a man or boy might be sacrificed, and this might also be done for success in war.

The third part of the volume, dealing with religion, begins with a most stimulating discussion of the meaning of the word Jwok (Juok), not only in Shilluk but also in those of the related languages sufficiently well known to permit comparison. So far as the Shilluk are concerned, Jwok is certainly the high-god, the creator, now but little concerned with mankind, but it is noted that disease might be spoken of as *jwok*, though (alternately) each disease has its own name, while in Shilluk folklore men endowed with super-normal powers may also be called Jwok; moreover, the actual practice of sacrifice to benefit a sick man suggests a closer connexion (on this occasion almost a synonymy) of Jwok and ancestral spirits. It may be added that certain spirits of the river and bush of considerable importance among the Acholi (who speak a simplified Shilluk dialect) are recognised by the Shilluk, though among these they have little importance.

The account of Jwok is followed by that of the *ajwogo* (*adjuago*), the 'man of Jwok,' or the 'good medicine-man,' as he has been called, whose actions are, generally speaking, social and beneficent even if they clash with European ideas; it is the *jalyat* who is the 'witch,' the evil medicine-man who by his magic kills people for his own ends, or, more generally, incited thereto as the result of private enmity.

The observations on totemism constitute an important addition to our knowledge. It should, however, be noted that the belief is less obvious, and, apart from exogamy, has less social importance, and is certainly less loaded with effect, than among such frankly totemistic tribes as the Dinka.

The fourth section of the work, entitled "Country and People," contains a deal of heterogeneous information, much of which is new, *e.g.* the political divisions of the country, the greater part of the life-history of the individual (pre-natal to burial), technology, forms of salutations, oaths, stories, riddles, and a most valuable *corpus* of more than 100 songs, providing much material for future analysis. The book concludes with a number of plates and useful technological diagrams.

BRENDA Z. SELIGMAN.

Experimental Embryology.

An Introduction to Experimental Embryology. By G. R. de Beer. Pp. iv + 148. (Oxford: Clarendon Press; London: Oxford University Press, 1926.) 7*s.* 6*d.* net.

MR. DE BEER has written an excellent little book. It is the first attempt in English to survey the field of experimental embryology since the publication of the late J. W. Jenkinson's "Lectures" in 1917, and in the interval much new work has been done. The author does not attempt to include an account of all this work; on the other hand, he has purposely selected from an extensive literature descriptions of those experiments which have a common bearing in elucidating the more essential problems. The consideration of the development and determination of the sexual characters has been deliberately excluded on the ground that this subject has been dealt with recently in works by Goldschmidt and Crew. This is perhaps to be regretted, since some of the best examples of the successful application of the experimental method might have been drawn from recent investigations in this branch of study, and many of them without encroaching on the subject matter of either of the two books referred to. It was inevitable, however, in a work of this size, that the author should select his material, and as it is, he has succeeded in covering a wide field. At the end of the volume is a tabulated list of the experiments cited, with due references to the authors and to the literature.

Mr. de Beer begins by pointing out the relation between descriptive and experimental embryology; in so doing he might have added that the relation is essentially the same as that between descriptive and experimental physiology. Embryology, like descriptive physiology, differs from morphology in the introduction of the time factor; that is to say, it deals with sequences of events. The study of the processes of salivary secretion or the œstrous cycle can be undertaken without recourse to experiments (unless the killing of the animal at a particular stage of activity be held to involve an experiment) in just the same kind of way as the tracing of the progress of development. But it is only by the use of the experimental method that we can study the mechanism of the secretion and the nature of the stimulus which produces it, or the interaction of the ovaries and the other organs concerned in accounting for the œstrous cycle. The subject of this book, therefore, is the experimental physiology of the developing animal.

After a chapter on fertilisation, in which Lillie's theory is duly set forth, the author proceeds to the consideration of parthenogenesis and the factors which activate the egg. The evidence from experiments on larval hybridisation is then separately discussed, and it is shown that the activating effect of the sperm can be distinguished from its hereditary effect. Sections follow on the relation between the sizes of nucleus and cytoplasm and the value of the chromosomes. Unlike a recent reviewer in NATURE (June 5, 1926, p. 781), the author adopts the view (in our opinion with justification) that the chromosomes are the bearers of the hereditary characters, and he points out further that experimental embryology provides evidence that each chromosome of the sets brought in by the nuclei of the sperm and ovum has a particular and essential part to play.

The next four chapters are on cleavage, and the internal and external factors in development are then discussed. There are admirable summaries of the important work of Child on 'axial gradients' in the rate of metabolism of the tissues, and that of Spemann and others on differentiation and the reverse process of reduction. The latter occurs normally in the resorption of the amphibian tail, or abnormally by starvation, as with the planarian. The self-regulating power of the organism is discussed under the head of 'regeneration,' as well as in a later chapter. The action of hormones as factors in development is illustrated by the part played by the thyroid in amphibian metamorphosis, and it is shown that the 'all-or-none' law, which Lipschütz has sought to apply to the working of another hormone, does not hold here. In the next chapter the author deals with the relation of nerve to muscle in embryonic growth. Finally, there is a brief review of development, in which certain general principles are discussed.

The author does well to remind us that "with regard to the term 'explanation' . . . ultimately nothing can be really explained." He might have elucidated the matter further by saying that the term is used in science to denote the process of co-ordination of facts whereby these can be brought under general schemes or laws which enable us to generalise and to predict. A distinguished physicist is reported to have said that a law of Nature is not a statement of fact but of policy. The test of the soundness of the policy or the validity of the law is that the events we expect are the events which come about. The author of the book under review is not certain whether the processes that go on in the living organism can be satisfactorily interpreted on a physico-chemical basis or whether they may "require non-physical categories to contain them." It is clear that the conceptions he employs as to the self-regulating capacity belong to teleological categories, like those relating to 'compensatory hypertrophy' in the physiological text-books. The only test of the validity of such conceptions is whether they enable us to advance our science by generalisation and prediction. If they do this, they reflect recognisable degrees of reality.

F. H. A. MARSHALL.

British Aphides.

The Plant Lice or Aphididæ of Great Britain. By Fred. V. Theobald. Vol. 1. Pp. ix + 372. (London: Headley Bros., 1926.) 25s.

IT is fifty years since the first volume of Buckton's monograph on British aphides was published. Since that time, plant lice have been widely studied in Europe and America, and more recently in

Japan and other countries. Mr. Theobald has studied the aphides of Britain for some thirty years, and has published numerous papers on them from time to time. Every one interested in insects, particularly economic entomologists, will welcome, therefore, the publication of this up-to-date monograph, based on the author's extensive studies.

The classification adopted follows closely that of Baker (1920), which is certainly the most rational and logical one in existence. It is proposed to deal only with the family Aphididæ, and this first volume is concerned with the sub-tribes Macrosiphina and Pentalonina. Fourteen genera and 133 species are recognised, and in addition four other species are noted in the appendix. Descriptions of the parthenogenetic females of the species together with keys are given, the salient external features being figured. In addition, notes on synonymy, food plants, localities and biology are added. The sexuales are unknown in many species of aphides, and it is surprising that in only nineteen of the above species are both sexual forms described in this volume. In five other species the male only is described, and in five further cases the sexual female only is described. It is not clear whether we are to conclude that the sexuales are unknown in all the other species, or whether they are omitted in some cases because they do not require special notice. For example, on p. 216 the apterous oviparous female of *Rs. ligustri* is stated to be abundant, but it is not described. Similarly, on p. 14 the sexual female of *C. rosarum* is referred to, but no description of it is given under that species.

A useful introductory chapter gives an account of the general morphological and biological features of the Aphididæ. The statement on p. 6: "The rostrum was formerly looked upon as the labium, but it is really an extension of the body," requires further explanation; the available embryological evidence indicates that the rostrum in Rhynchota is labial in origin. The old nomenclature for the wing veins is used. One feels it might have been better to have adopted the nomenclature of the Comstock and Needham system, as Patch has worked out the homologies in aphides.

Two misprints not included in the errata have been noted: the genus Aphidiella should read Aphidella; the specific name *M. scropulariæ* should read *scrophulariæ*.

Entomologists owe a great debt of gratitude to the author for the laborious task he has so faithfully carried through, and will look forward to the early publication of further volumes. J. D.

Our Bookshelf.

A Nineteenth-Century Teacher: John Henry Bridges, M.B., F.R.C.P., sometime Fellow of Oriel College, Oxford, and late Medical Inspector to the Local Government Board. By his Niece, Susan Liveing. Pp. xv + 262. (London: Kegan Paul and Co., Ltd., 1926.) 7*s.* 6*d.* net.

DR. J. H. BRIDGES was the most philosophic and scientific mind among the leaders of the positivist movement at the end of the last century, and it is good to know that he will at last be recalled to mind, while many who knew him in person are still alive. For he was unique in many ways, a most attractive and lovable character, above all a thoroughly typical Englishman who had succeeded in putting himself in the right European and international position without forfeiting a jot of his national qualities and attachment. He became, by his training at Oxford and as a doctor and by his attachment to Comte, the most all-round man of his time, specially interesting to readers of NATURE and contemporary men of science generally.

After taking the ordinary course of 'Literae Humaniores' at Wadham, Dr. Bridges qualified himself thoroughly as a physician, and throughout his life kept the balance true between scientific and literary and historical studies. Had he not been preoccupied with the organisation of the Poor Law infirmaries of London, there can be no doubt but that he would have contributed largely to historical writing of the type now so much needed, namely, synthetic history, in which the due place of scientific thinking in building up the social structure is duly recognised and maintained. As it was, he wrote a number of valuable short studies, of which Mrs. Liveing gives a useful list. Apart from its success as a personal portrait, her book is well worth getting for its inimitable picture of the life in the evangelical parsonage where Bridges spent his youth, and to which he always turned back with affectionate memories in spite of his later developments. One must read the literal account of all this in Mrs. Liveing's authentic narrative before one can believe it, and it would be a pity to spoil the enjoyment of this or of the delightful figure of his mother by quoting any fragments. The whole is the best recent biography which has appeared, sympathetic, well-balanced, sufficiently detailed, and not too long. It gains much in value by the extremely interesting study of positivism and science by Prof. Patrick Geddes.

F. S. M.

Tafeln zur Bestimmung des Wasserdampfgehaltes der Luft mittelst eines Haarhygrometers und Thermometers gerechnet und erläutert. Von Dr. J. N. Dörr. *Anleitung zur Behandlung eines Haarhygrometers und zur Verwertung fur die lokale Wettervorhersage.* Von Dr. A. Schlein. (Wien: Selbstverlag von Dr. A. Schlein, 1925.) n.p.

THESE tables have been prepared for use in place of a similar set of tables by Perntner, which were printed as an appendix to Jelinek's "Psychrometertafeln." They are issued by the Austrian Central Institute for Meteorology and Dynamics for use at Austrian meteorological stations. The tables give vapour pressure in millimetres in terms of the two arguments, dry-bulb temperature and relative humidity, the latter to be observed by means of the hair hygrometer. In a general discussion of the question of measurement of humidity, Dr. Schlein recommends the use of the hair hygrometer in preference to other methods, quoting a statement by Pircher that the indications of the hair hygrometer are independent of the air-pressure and of wind velocity. He also quotes a remark made by de Saussure in 1783: "When all other possible hygrometers have been tried, one will always fall back on the hair hygrometer."

There is a brief account of the precautions necessary to obtain accurate results by the use of Lambrecht's polymeter, which appears to be the standard type of instrument used by the Austrian service. This is followed by some remarks on the use of the readings in local forecasting, particularly forecasting of frost. A conversion table is given for converting pressure in millimetres to millibars. The discussion by Dr. Schlein will be read with interest by all who are interested in questions of humidity.

The tables, which were prepared by Dr. Dörr, are printed in a very clear and convenient form, and will doubtless be regarded as the standard tables for use when relative humidity is observed directly.

Primitive Trade: its Psychology and Economics. By Prof. Elizabeth Ellis Hoyt. Pp. vi + 191. (London: Kegan Paul and Co., Ltd., 1926.) 7*s*. 6*d*. net.

If it were necessary to classify Miss Hoyt's "Primitive Trade" as anthropological, economic, social, or psychological science, it would be difficult to assign it to its proper category, for it belongs to all. It is essentially a study of values, and all the various influences, social, religious, customary, and personal, which can be held to bear in determining values have been brought into the account. Miss Hoyt visualises the central problem of economics as a study of the attempt to arrive at a 'perfect price.' This involves a full satisfaction of needs, while how it is to be attained necessitates a study of the underlying psychological processes and their development. This in turn is dependent upon a survey of the facts—the data provided by the anthropologist showing what people actually do at various stages of culture when they fix 'price' either explicitly or implicitly. She begins with the consideration of interests and passes on to the objectifying of needs, and shows how these interact and are brought into operation in the beginnings and extension of trade. Miss Hoyt has clearly been strongly influenced by Dr. Malinowski's studies of primitive trade and economic conditions in the Trobriands, which demonstrated clearly that in determining the factors of value, we must extend our vision far beyond the vistas of the economist of the schools. Her treatise is a stimulating and really original contribution to the literature of economic science.

Microscopic Fresh-Water Life. By F. J. W. Plaskitt. Pp. xi + 278 + 14 plates. (London: Chapman and Hall, Ltd., 1926.) 13*s*. 6*d*. net.

It is with regret that one learns of the sudden death of the author of this book almost immediately after its publication. But though the author has passed away, his book remains, and sentimental considerations must not prevent a reviewer from giving a plain statement of his impression of it. The book is meant primarily to assist the beginner and to instil into him some enthusiasm for that most fascinating of hobbies, the study of pond life. In his desire to popularise this subject, the author has certainly written a very attractive and interesting book. He had considerable experience of the subject, and has therefore been able to give much valuable information on the habitat and the best method of collecting fresh-water organisms. Both animals and plants are treated very fully. Most of the illustrations are admirable, and there are a great many remarkably fine photo-micrographs, the majority of which are taken with dark-ground illumination.

There is a useful glossary at the beginning of the book, and a really valuable chapter has been written by Mr. Chas. D. Soar on Hydracarina.

Unfortunately, the book contains much that is both incorrect and unscientifically written. A list of a few such blemishes has been sent to the publishers.

A. G. L.

Riemannian Geometry. By Prof. L. P. Eisenhart. Pp. vii + 262. (Princeton: Princeton University Press; London: Oxford University Press, 1926.) 13*s*. 6*d*. net.

The recent physical interpretation of intrinsic differential geometry of spaces has stimulated the study of this subject. Riemann proposed the generalisation, to spaces of any order, of Gauss's theory of surfaces, and introduced certain fundamental ideas in this general theory. Bianchi, Beltrami, and others made substantial contributions to the subject, which was extended by Ricci with the use of tensor analysis and his absolute calculus. Recently there has been an extensive study and development of Riemannian geometry, and the book before us aims at presenting the existing theory.

The first chapter contains an exposition of tensor analysis sufficient for the reader who has not previously studied this subject. Most of the contributors to the theory of Riemannian geometry have limited their investigations to spaces with a metric defined by a positive quadratic differential form. The theory of relativity, however, deals with spaces with an indefinite fundamental form, and the former restriction is not made in the present book. Although many results in the older theory have been modified to meet the demands of relativity, much remains to be done in the unrestricted field.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. *No notice is taken of anonymous communications.]*

Thermodynamic Diagrams in the Study of the Upper Air.

SOME months ago a letter appeared in NATURE (November 14, 1925, vol. 116, p. 709) from Mr. J. S. Dines, directing attention to the usefulness of setting out the results of the observations of pressure, temperature, and humidity in the upper air upon a diagram in which temperature and entropy are the co-ordinates, entropy and the logarithm of potential temperature being convertible terms so far as the atmosphere is concerned.

Circumstances have led me to pay further attention to that subject, and I find that the diagrams may be very useful in other ways, especially as a means of evaluating the height of an ascent.

Curiously enough, the most direct avenue to the determination of the height of a point is a previous determination of the geopotential at the point—by geopotential is to be understood the work which would be required to lift unit mass, a gram of balloon, for example, or in England, I suppose, a pound of aeroplane, against gravity to the level of the point.

A very simple calculation shows that if the graph of the ascent be set out on an entropy-temperature diagram, which involves no observations except those of pressure and the corresponding temperatures —the primary observations in all soundings or height measurements of the upper air—the geopotential difference between the start and the finish (or any other point on the graph) is made up of two terms. The first is the work done by unit mass in describing the graph, which is in fact proportional to the area that lies between the graph on the left, the vertical of absolute zero on the right, and the two horizontal lines of equal entropy, top and bottom. This sounds very alarming, but on the diagram it only means running a planimeter round an area. The second term is proportional to the temperature difference between start and finish, and is, in fact, proportional to the difference of *pv* for unit mass between the start and the finish.

Expressed otherwise, the first term is the dynamical equivalent of the heat which must be supplied to the ascending unit to keep it in thermal equilibrium with its environment throughout its journey; and the second term is the equivalent of the heat taken from the ascending unit itself in consequence of the reduction of its temperature.

With a planimeter one can allow for all the sinuosities of the graph, an allowance which, so far as I know, is not made in ordinary practice when evaluating the height from the trace of a meteorograph.

The calculation is thus simple enough, in spite of the forbidding words used in connexion with it; and it can be verified by making a graph for the ascent, referred to pressure and temperature, with pressure on a logarithmic scale and temperature linear. Again it is only the measurement of an area on the paper.

The step from the geopotential thus computed to height in the ordinary sense is the simple one of using a conversion table. The process is much simpler than the other way round, because the variable *g* only comes into the conversion table.

I refer to these methods for a special reason. Prof. V. Bjerknes and others insist upon the propriety of using 'levels' (expressed numerically as geopotential) instead of ordinary heights in all dynamical study of the atmosphere; and, without a consciousness of special pleading, it is scarcely possible to resist their contention.

The ordinary exculpation for using heights instead of 'levels' is that we compute heights that one can see; and altimeters, for example, are graduated in heights; but when we find that it is really 'levels' that are easy to calculate and come directly from our curves by so simple a process as measuring an area, we may think it worth while, not only in meteorology but in aeronautics also, to learn to think and talk and work in levels and not in the customary but more complicated dynamical conception of heights.

NAPIER SHAW.

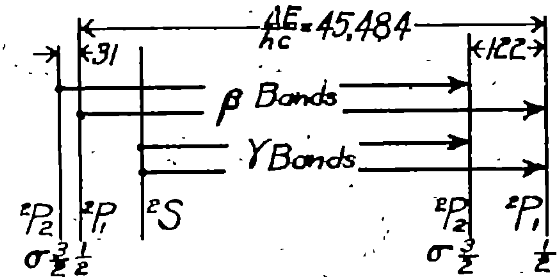
The β Bands of Nitric Oxide.

As has been shown by the work of E. P. Lewis and of Strutt and Fowler, the spectrum of active nitrogen consists of three systems of bands (α, β, and γ bands of Strutt and Fowler), of which only the α bands (part of the first positive nitrogen bands) appear if oxygen is carefully excluded. The investigations of Lewis, and later those of Strutt, indicated that the γ bands (third positive nitrogen bands) and β bands are both due to the presence of small amounts of oxygen as nitric oxide. Dr. H. Sponer has recently shown (Sponer, NATURE, 117, p. 81, Jan. 16, 1926, and Sponer and Hopfield, *Phys. Rev.*, **27**, 640, 1926) that this is certainly true, and that the β and γ systems have a common final state which is the normal state of NO. This is in agreement with the calculations of Birge and of Mulliken, which indicated that, with a certain assignment of quantum numbers, the vibrational constants for the final state are identical in the two systems. In a recent paper in the *Philosophical Magazine* (Sept. 1926, p. 621), Dr. R. C. Johnson and Mr. H. G. Jenkins give equations for the frequencies of the β system heads in terms of the vibrational quantum numbers. The proper assignment of quantum numbers was self-evident after the common final state of the β and γ bands had been recognised.

The β bands were first observed by Lewis in 1899 while studying the nitrogen afterglow. These bands were later measured and arranged in Deslandres' progressions by Fowler and Strutt, using photographs obtained with a quartz spectrograph. We have now photographed the bands in the second order of the 21-foot concave grating at Harvard University, using as a source active nitrogen to which enough air had been added to quench completely the α bands. Practically all of the β bands hitherto reported appear on our plates, and we have undertaken a comprehensive analysis of the system.

It has recently been shown (cf. R. T. Birge, NATURE, Feb. 27, 1926; R. S. Mulliken, *Phys. Rev.*, Nov. 1925 and Sept. 1926) that the electronic states of many molecules show a close parallelism to those of certain corresponding atoms. In particular, these analogies indicate that the NO molecule should have a doublet *P* (^2P) normal state like the aluminium atom. Assuming that the γ bands correspond to a $^2S \longrightarrow {}^2P$ transition in NO (cf. Mulliken, *l.c.*, and *Phys. Rev.*, Dec. 1926), the observed doublet separation $\Delta\nu$ of 122 wave-number units for these bands should represent the separation between the $^2P_1$ and $^2P_2$ sub-levels of the ^2P normal state. Now the β bands also show a double electronic frequency for which, according to our analysis, $\Delta\nu = 91{\cdot}05$. Assuming identity of the final states of the β and γ bands, we may reasonably conclude that this $\Delta\nu$ represents the difference between an electronic doublet separation $\Delta\nu = 31$ for the initial state of the β bands and the separation $\Delta\nu = 122$ of the final state. The relations just discussed are illustrated in Fig. 1 (the energy levels are not drawn to scale).



$\frac{\Delta E}{hc} = 45{,}484$

σ $\frac{3}{2}$ $\frac{1}{2}$

Fig. 1.

Each of the two heads, in each β band, corresponds to a series of lines which constitutes a P and an R branch of the ordinary type, except that in the high-frequency sub-band *two* lines are missing in the otherwise continuous series, and *four* in the low-frequency sub-band. Quantum analysis shows that each complete band involves four distinct sets of rotational levels, two initial and two final, *i.e.* one set for each of the four electronic states above assumed. The analysis shows further that the rotational quantum numbers are *integral* in all four cases if the rotational terms are of the form $B(j^2 - \sigma^2) + \ldots$ The missing lines then correspond to the rotational transitions $0 \rightarrow 1$ and $1 \rightarrow 0$ in the high-frequency, and to $0 \rightarrow 1$, $1 \rightarrow 0$, $1 \rightarrow 2$, and $2 \rightarrow 1$ in the low-frequency bands. They are completely accounted for by $\sigma = \frac{1}{2}$ (for both initial and final states) in the high-frequency and $\sigma = 1\frac{1}{2}$ in the low-frequency sub-bands, since j is necessarily limited to values equal to or greater than σ. Here σ is an electronic quantum number; $\sigma h/2\pi$ is the resultant electronic angular momentum of the molecule, which is here directed along the internuclear axis. The high-frequency bands then correspond to a transition $^2P_1 \rightarrow {}^2P_1$ and the low-frequency bands to a $^2P_2 \rightarrow {}^2P_2$ transition. This interpretation is completely in harmony with the generalisations of one of the writers (Mulliken, *l.c.*) in regard to j and σ values, etc., in odd and even molecules.

The above description requires slight modification in that the lines of the higher frequency bands are very close doublets, the separation of which is apparently proportional to j. They begin to be resolved, on our plates, at about $j = 16$, where the separation is 0·24 wave-number units. This shows that the rotational levels in one, or both, of the $^2P_1$ states are double.

Intensity relations among the band lines give strong support to the above interpretation. For the intensity I of any line, one expects $I = ie^{-E/kT}$, where E' is the energy of the initial state, T the absolute temperature, and i a probability coefficient. The observed intensities of the P and R branches rise to a maximum and then fall, the distribution being almost completely symmetrical in the two branches, as in the CuH and HCl bands. For high j values, however, the P branch is somewhat the stronger, as would be expected due to the factor $e^{-E/kT}$. At first sight the bands appeared to contain only P and R branches, but on careful inspection a very weak Q branch was found in each band, with the intensity *decreasing steadily* from the first line. The Q branch is much weaker for the higher frequency ($^2P_1$) than for the lower frequency ($^2P_2$) bands. In the former the first line is fainter than the first lines in the P and R branches, but in the latter it is somewhat stronger. All the above intensity relations are in exact accord with the intensity formulæ (for the i values in the equation above) deduced with the aid of the summation rule by Hönl and London (*Zs. für Physik*, vol. 33, p. 803, 1925) for the case where the electron transition involves no change in σ. Even the particular values $\frac{1}{2}$ and $1\frac{1}{2}$ for σ are definitely justified by the observed intensities in the Q branches (according to Hönl and London's equations the intensities of the Q lines should be approximately proportional to σ^2/j).

Preliminary values for the moment of inertia and internuclear distance in NO have been calculated. In the initial states the latter has the values $1{\cdot}44 \times 10^{-8}$ and $1{\cdot}40 \times 10^{-8}$ cm., in the final (normal) states the values $1{\cdot}16 \times 10^{-8}$ and $1{\cdot}14 \times 10^{-8}$ cm. We have also found a difference in the vibration frequency for the two components of each doublet, which is evident from gradual changes in the frequency separation of the double bands. In the normal state it is about one part in 5000, and in the excited state somewhat larger and apparently in the opposite sense.

From the data now available it will be possible to calculate exactly the specific heat and magnetic susceptibility of gaseous nitric oxide.

Referring again to Fig. 1, we see the possibility of two other transitions, $^2P_2$ to $^2P_1$ and $^2P_1$ to $^2P_2$, which, however, are completely absent from our photographs. Their absence and the presence of the other two transitions are in agreement with the new theory of Hund (*Zs. für Physik*, vol. 36, p. 657, 1926). A complete account of our results will appear later, probably in the *Physical Review*.

Inheritance in *Gammarus chevreuxi* Sexton.

An account was recently given of some new mutations in *Gammarus chevreuxi* Sexton (Nature, Feb. 6, 1926). A certain 'white-body' mutation did not behave in a simple Mendelian manner. In this mutant the body is devoid of the normal green and brown pigments. The mutant is recessive to the normal 'black-eyed' form, and the homozygote mutant has black eyes and white body (white-body Black). With certain exceptions to be considered later, 'White-body' is recessive to another mutant, the 'New Red' (with red eyes and normally pigmented body). But if homozygous for 'White-body,' the 'Red' fails not only to develop body-colour but also the red eye colour; a 'White' individual in both eyes and body results.

That these 'Whites' do carry 'Red' can be seen by crossing them with normals, Reds appearing in F_2.

From this it is evident that a cross between 'White' and 'New Red' should by simple Mendelian principles yield in F_1 either all Red-eyed individuals or 50 per cent. Red-eyed, 50 per cent. 'Whites,' according as the 'Red' individual was homo- or heterozygous for the body-colour factor. This does occur when a 'White' male is crossed with a 'New Red' female. But the offspring of a ‘White’ female and a ‘New Red’ male are *always white*. This is no question of sex-linkage, since both males and females homozygous for the ‘White’ mutation can be found.

The F_1 Whites are by no means all simple ‘Whites.’ Many of them belong to the class of ‘changelings’; these are ‘White’ at birth, but take on the appearance of ‘Reds’ as life proceeds. Broods consist either of all ‘changeling’ or 50 per cent. Changeling to 50 per cent. true ‘White’ according as the Red male is pure, or is heterozygous for ‘White.’ Changelings can be obtained not only from ‘White’ mothers, but also from certain matings of ‘White-body Black’ mothers, if carrying New Red.

The following conclusions have been invariably substantiated in the history of the stocks:

(1) Changeling whites occur only where ‘Reds’ would be expected.

(2) They *always* have a mother with a *white* body.

(3) They always behave genetically simply as Reds, but

(4) They are always heterozygous for ‘white-body.’ This last conclusion follows from their maternal derivation, since a ‘white-body’ individual is always homozygous for that mutation.

These facts seem impossible to fit into an ordinary Mendelian scheme, but the following considerations appear to provide a working hypothesis. Normal individuals possess a gene for ‘body colour’ which corresponds to the ‘white-body’ mutant gene. Individuals homozygous for the ‘white-body’ factor (whether ‘White’ or ‘white-body Black’) cannot lay down body pigment or red eye pigment. So long as its normal counterpart the ‘body-colour’ factor is present, the presence of the ‘Red’ factor ensures the manufacture of these pigments. We may therefore suppose the normal ‘body colour’ gene is concerned with the manufacture of some precursor from which pigment can be formed. In the ‘white-body’ mutant, failure to form the precursor consequently gives the ‘Red’ factor no precursor on which to act; a ‘White’ individual results.

‘White-body’ females (‘White’ or ‘white-body Black’) are unable to lay down any precursor in the egg-cytoplasm; its abundance in the normal egg is testified by intense pigment formation in the ovaries. When, therefore, a white-body female is crossed with a ‘New Red’ (possessing the normal ‘body-colour’ factor) the F_1 embryo is at a disadvantage. It possesses the necessary factors to change precursor into pigment, but at first the precursor itself is absent. (The amount brought in by the cytoplasm of the sperm may be neglected.) The embryo certainly possesses the ‘body-colour’ factor introduced by the sperm, but this must make a store of precursor *ab initio*, and probably this cannot be done until feeding commences. In any case it will be long before the deficit is made good, and it is thus easy to see why the embryos are ‘white’ on hatching. But as feeding and growth proceed the precursor deficit will be gradually made good; pigment can be laid down and the animal can assume its true ‘genetic’ appearance of ‘Red.’

In the converse cross, White male by Red female, the eggs have the normal amount of precursor, so that the genetically ‘Red’ embryos are at no disadvantage and can form pigment immediately in the normal manner.

Further results may be predicted from this hypothesis. A ‘Red’ female forms eggs containing the precursor. If she carries ‘white-body’ and is mated with a male containing ‘white-body,’ some embryos will not possess the ‘body-colour’ factor and cannot therefore form the precursor. But the initial presence of a limited supply might allow the embryo to form pigment for a short time, though later it would be unable to do so. Consequently we might expect retrograde ‘changelings’ genetically ‘white,’ but starting with a faint colour which does not develop or is lost as life proceeds. Cases of this have been observed.

Again, except for the possession of the black eye, the ‘white-body Black’ resembles a true ‘White,’ and its relation to ‘Normal Black’ is the same as the relation of ‘White’ to ‘Red.’ Therefore ‘white-body Black’ changelings should occur, which later develop into ‘Normal Blacks’ and behave genetically as such. These cases have also been found.

The phenomena described above are of interest because they seem to present a clear case of the relation of the cytoplasm to Mendelian factors. It should be understood that no question of cytoplasmic inheritance is involved.

The hypothesis outlined is simply a physiologically legitimate extension of the Mendelian theory. It may be illustrated by the not improbable supposition that the basis of the actual pigment of the body and the red pigment of the eye is some substance never formed by the animal itself but is of vegetable origin. In the normal egg sufficient of this basal substance (or precursor) is contained in the yolk to provide what is necessary for the body-colour and red eye-colour of the newly born animal, later supplies coming directly from the food. When the yolk of the egg contains no basal substance, the red eye colour and the body-colour are absent in the just-hatched young, though some or all of these young are genetically ‘Red.’ As they feed they obtain the necessary basal substance from their vegetable food, and by converting this into special pigments become normal red-eyed animals with full body-colour. These are the ‘Changeling whites.’ It ought to be possible to test this supposition experimentally.

The Formation of Twin Metallic Crystals.

THE paper by Messrs. Carpenter and Tamura in the November number of the *Proceedings of the Royal Society*, on “The Formation of Twin Metallic Crystals,” presents a picture of the twin boundary which seems to me to be incorrect. The authors have assumed that the two halves of a twinned crystal are derived from each other by reflection in a plane which does not pass through atom-centres, but passes, in the case of face-centred cubic crystals, exactly half-way between two consecutive planes, through atom-centres, of the form $\{111\}$. This is improbable, because it requires, as its proponents themselves point out, abnormally small interatomic distances across the twinning plane, and correspondingly high local stresses, for which there is no experimental evidence. It seems much more reasonable to suppose that the two halves of the twinned crystal are reflections of each other in a $\{111\}$ plane which *does* pass through atom-centres. This picture of the boundary involves no abnormal distance between any atom and its immediate neighbours. Experimentally observable relations between twins are, of course, the same on either hypothesis.

Messrs. Carpenter and Tamura have been led, on the basis of their hypothesis, to conclude that in the diamond-like structures of silicon and germanium, twinning must involve even greater local distortions than those they have accepted as necessary in copper or nickel. If the view here advocated is the correct one, however, it appears that twins in silicon and germanium may have the relation of mirror-images in a common plane, through atom-centres, of the form {100}. This requires no abnormality in the least interatomic distances, and the twins can only be made one continuous crystal by rotation of either half through 90° about a normal to their common plane at a common atom-centre, or by a geometrically equivalent process. (In the case of twins on a {111} plane the corresponding rotation is through either 60° or 180°.)

L. W. McKEEHAN.

IN reply to the remarks of Mr. McKeehan regarding the paper which we have recently published, the point in question is whether twins of metallic crystals form a plane which passes through atom-centres. According to the hypothesis brought forward by us, the twinning of the face-centred cubic lattice takes place on the octahedral planes. Thus the two halves are arranged in a symmetrical position after a rotation of 180° about an axis normal to the octahedral plane. Obviously, in this case, the twinning plane does not pass through any atom-centres. In the face-centred cubic lattice the closest interatomic distance is $L/\sqrt{2}$. When twinned in the way mentioned above, however, the closest distance apart between atoms along the twinning plane is $L/\sqrt{3}$, where L is the lattice parameter in both cases. The change in the closest interatomic distance on twinning appears to be the cause of the local stress to which Mr. McKeehan refers, although, as he says, "there is no experimental evidence" regarding this point.

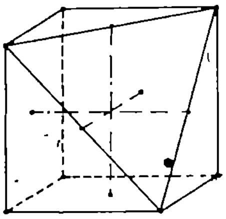

FIG. 1.

His view is apparently as follows: Two portions of two face-centred cubic lattices, both having the same geometrical form as in Fig. 1, are in contact with a plane of the octahedron passing through atom-centres so as to form the structure of mirror-images. The two portions thus share three corner atoms and three face-centred atoms in the octahedral plane. In this case, however, so far as the unit lattice form is concerned, the face-centred cube is not twinned but simply grouped in a reverse position.

With regard to the question of twinning in tetrahedral cubic crystals, Mr. McKeehan has suggested that a possible twinning plane is the cubic plane which passes through atom-centres. By a rotation of either half of the cube through 90° about an axis normal to that plane, mirror-images result, but the relations of the crystallographic axes do not change. The planes of densest atomic concentration are, however, the dodecahedral planes on which twinning does not occur. From this it would appear that the octahedral planes which possess the next densest atomic concentration are likely to be possible twinning planes. On the basis of this assumption, the closest interatomic distance of the twinned tetrahedral cubic lattice is $L/2\sqrt{3}$ instead of $\sqrt{3}L/4$, which is the closest interatomic distance of the tetrahedral cubic lattice. This is apparently the conclusion which Mr. McKeehan has considered improbable because of high local stress. It is suggested that, as in the case of the twinning of face-centred cubic crystals, if two parts of the tetrahedral cubic lattice (both having the same geometrical form) are in contact with a plane of the octahedron passing through atom-centres, the structure of mirror-images can be obtained without a change in the closest interatomic distance. These mirror-images, however, are not called twins of the tetrahedral cubic lattice. The crystallographic axis takes up a twinning position relative to the other, thereby resulting in the change of orientation. As a whole, the result is similar to that which we have assumed.

The Scattering of Gamma Rays.

IN a letter to NATURE of December 4, Prof. J. A. Gray pointed out that a study of radiations of shorter wave-length than 0·02 Å.U. is complicated by the scattered radiations accompanying them, about which little is known. That gamma rays under certain experimental conditions appear to become less penetrating as they pass through matter was shown by Dr. Gray in 1913. Recently it has been shown by me (*Phil. Mag.*, Oct. 1926, p. 785) that the scattered radiations were considerably softer than the gamma rays producing them, and evidence was given of a comparatively soft radiation from air penetrated by gamma rays. Confirmatory experiments have since been made, a brief reference to which may not be without interest.

A given source of gamma rays was set up at different distances from an electroscope and, for each position of the source, a curve was obtained showing the apparent transmission of these rays through lead. With a lead electroscope of wall thickness 1·0 cm. the apparent transmission of lead was independent of the distance of the source from it. When the thickness of the wall was reduced to 0·17 cm. the slope of the transmission curves became less and less steep as the source was moved farther from the electroscope.

The curve, shown as Fig. 1, was obtained when a radon source equal to 127 millicuries was placed at 71 cm. from an electroscope of aluminium 0·008 cm. thick. Over the range AB of the curve the recorded ionisation is due almost solely to radiation scattered from the air around the electroscope. When the lead filters are so thick that they begin to screen this air from the direct primary rays, the ionisation decreases as shown by the curve. The transmission of the scattered radiation through aluminium was found for the experimental conditions represented by point C in Fig. 1, namely, the primary beam screened by nearly 30 cm. of lead. The scattered radiation

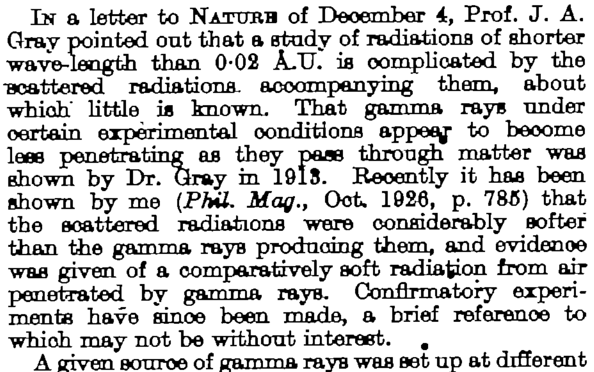

FIG. 1.

is heterogeneous, the coefficient of absorption in aluminium of the softest and hardest components being respectively 39·7 cm.$^{-1}$ and 0·051 cm.$^{-1}$. In order to determine the nature of the radiation scattered from air it is being subjected to a magnetic field, and experiments of this kind are in progress.

Some experiments to determine the effect upon ionisation measurements of lining the electroscope with different substances have also been made. A comparison of the curves, showing the transmission of radiation through lead obtained with an electroscope (*a*) unlined and (*b*) lined with cardboard 0·18 cm. thick, affords very definite information about the quality of the radiation responsible for the ionisation observed. It was found that, when the ionisation was due to radiation of the same wave-length as the primary gamma rays, the insertion of the lining increased the apparent transmission of a filter, the transmission value for a lead filter 10·1 cm. thick being 1·27 times that found with the lining removed. When the ionisation was due partly to scattered radiation, the apparent transmission of the filter was decreased by inserting the lining into the electroscope. The unlined electroscope in this case gave a transmission figure for a lead filter 6·0 cm. thick, which was 1·39 times that found when the electroscope was lined with cardboard. One has therefore a means, likely to prove useful in absorption experiments, of detecting any change in the quality of the radiation entering the electroscope, with the thickness of the filter placed in the primary beam.

Multiple Chromosomes and Reduction Division in Flowering Plants.

IT has been the general practice to speak of the chromosomes shown in the metaphase plates in the root-tips (and other somatic tissues) of flowering plants as single chromosomes. They are never, it seems, called bivalents, dyads, or disomes; though they always show a fine longitudinal split distinctly, in correctly fixed preparations. The chromosomes of the late prophase and first metaphase of the maturation divisions in flowering plants have, in my opinion, a close parallelism to those of the somatic divisions; in that the two chromatids of any one of the two homologous chromosomes are rendered visible only through the appearance of a fine longitudinal split, seen in correctly fixed preparations.

Hence it seems we need not necessarily call such a split chromosome (in flowering plants) a bivalent, dyad, or disome. It seems more convenient to call it a single chromosome, as in the case of the somatic division, and to speak of its two halves as chromatids, not as chromosomes; and this in fact seems to be the usual practice. Similarly, at the first anaphase and second metaphase, where the two chromatids have usually separated, except at the points of constriction, we usually, it seems, call the double *V*, etc., as it proceeds to the pole, a single chromosome. When it appears again in the second metaphase plate, as a double *V*, or a four-lobed cross, we again usually call it a single split chromosome. Hence we may perhaps define a single individual chromosome as normally consisting of two halves (chromatids) which have not yet completely separated. When they have *completely* separated, we have two chromosomes.

The reverse does not hold. For when two completely separate chromosomes come together (as in the prophase of maturation) they do not form a single chromosome, but a bivalent, dyad, or disome; and show double in well-fixed preparations. (The above seems to embody the prevailing usage with regard to flowering plants.)

The reduction division, in one of the old senses of the term—namely, reduction in the number of each gene from two to one—has, with the discovery of segmental interchange (crossing-over), ceased to have a signification, as Bridges has already pointed out.

In the second meaning of the term, namely, a reduction in the number of chromosomes, it seems still available. Using the limits of the term 'chromosome' as defined above, at the first maturation division the reduction is from nuclei with n bivalents, which must of course count as $2n$ chromosomes, to nuclei containing only n chromosomes. Hence the reduction division in the diploid flowering plants yet examined is the *first* of the two maturation divisions. This is confirmed by true triploid plants, in which the reduction metaphase has n trivalents, giving $3n$ chromosomes, as defined above. There are formed, after reduction, nuclei with groups of split chromosomes, each consisting of $2n-p$, where p has the values from 0 to n. Here again there is a reduction from $3n$ to something between $2n$ and n. Also in some haploid plants at least, with n single chromosomes (each presumably consisting of two chromatids), these chromosomes proceed to either pole without distinctly splitting, and split there. In this case there is a reduction from n to $n-p$, where p has the values from 0 to n.

Colorimetric Determination of the Oxidation of Hæmocyanin.

IN a recent paper confirming a previous finding by myself (*British Journal of Experimental Biology*, vol. 3, 1925) to the effect that the hæmocyanin of Cancer has minimum affinity for oxygen at a *p*H *circa* 7·0, Stedman and Stedman (*Biochemical Journal*, vol. 20, 1926) make the following comment on the colorimetric method:

"Although the colorimetric method might be expected to give accurate results and possesses the advantage of being rapid and simple, it is evident that curves obtained by this method under different conditions of acidity will not be comparable unless the standards are in each case maintained at the same degree of saturation. This condition will not be fulfilled in the case of hæmocyanin from Cancer and Homarus, if the standards are in equilibrium with air and the temperature is as high as 23° C. It is improbable that they were fulfilled at the slightly lower temperature of 18·7° employed by Hogben in the case of Cancer serum. . . . While the colorimetric method is undoubtedly capable of indicating the general influence of *p*H on a particular hæmocyanin, the results so obtained can have no quantitative significance unless care is taken to avoid the sources of error indicated above."

This criticism is surprising in view of the fact that the standards used, as explicitly mentioned both in published statement and in personal communication to the Stedmans, were prepared from normal serum of Cancer. It has been shown by these authors (*Biochemical Journal*, vol. 19, p. 547) that the normal serum of Cancer at room temperature is 88·1 per cent. saturated at an oxygen partial pressure of 21·7 mm., and 100 per cent. saturated at 80 mm., *i.e.* at half the partial pressure of oxygen in the atmosphere.

Moreover, their curve on p. 548, fig. 1, shows that the normal serum of Cancer is fully saturated at little over 40 mm. But if this were not so, it is not necessary to subject the serum to a pressure of 360 mm. oxygen to ascertain whether the blood is fully saturated. Since the curve for normal serum is itself determined as a preliminary procedure, such information is provided by the fact that over the greater part of the range of pressures employed, the curve is asymptotic to a line parallel with the abscissa.

I may further add that the colorimetric method employed is not, as the Stedmans state, a modification of the one proposed by Redfield and Hurd. The colorimetric method for determining the dissociation curve of hæmocyanin advocated by Mr. Pantin and myself (*Jour. Marine Biol. Ass.*, 1925) is in both essential points entirely different from that which Redfield and Hurd applied to the study of Limulus.

Decomposition of Nitrogen Pentoxide.

IN a recent paper read to the Chemical Society on December 2 last, I described experiments which show that when nitrogen peroxide is illuminated by light from the mercury vapour lamp a photochemical stationary state of the nature

$$2NO_2 \underset{\text{dark}}{\overset{\text{light}}{\rightleftarrows}} 2NO + O_2$$

is set up. This change involves a slow but perfectly reversible pressure increase in the gas when illuminated. The light from the mercury vapour lamp between 4360 Å.U. and 3650 Å.U. was shown to be probably wholly photochemically active, but the experiments did not show definitely if light of longer wave-length than this contributed to the effect, since the mercury spectrum is weak between 5460 Å.U. and 4360 Å.U. In view of these results, it does not seem advisable to retain Fazel and Karrer's hypothesis of the photochemical decomposition of nitrogen pentoxide in the presence of nitrogen peroxide (*J.A.C.S.*, 28, 2837, 1926). Arguing from the apparent analogy with other photosensitised systems, these authors suggest that photoactive molecules of NO_2 activate molecules of N_2O_5 by collisions of the second kind, and bring about the decomposition of the latter.

In view of the experiments referred to above, a more probable explanation of the effect of the nitrogen peroxide would seem to be according to the following scheme:

$$(1)\ 2NO_2 \xrightarrow{\text{light}} 2NO + O_2;$$

$$(2)\ NO + N_2O_5 \longrightarrow 3NO_2.$$

In the absence of N_2O_5 the reverse of equation (1) occurs. If nitrogen pentoxide be added to the system, reaction (2) occurs in preference to the reverse of reaction (1), since it is a bimolecular change, while the latter is definitely termolecular (Bodenstein and Lindner, *Zeit. Phys. Chem.*, 100, 87, 1922). It would therefore appear that the decomposition of nitrogen pentoxide is not a true photosensitised reaction, but rather a secondary dark reaction occurring between the nitrogen pentoxide and one of the products of photochemical decomposition of nitrogen peroxide. It is obvious from this explanation that nitrogen peroxide should have no effect on the thermal decomposition of nitrogen pentoxide, in agreement with the experiments of Hirst (*J.C.S.*, 127, 657, 1925), and of White and Tolman (*J.A.C.S.*, 47, 1240, 1925).

Winter Thunderstorms in the British Islands.

APPEALS were made on several occasions during last winter for reports of any thunder or lightning which might be observed during the first three months of 1926. The census of storms was carried out in conjunction with the Meteorological Office, and efforts were made to secure the co-operation of observers in all parts of the British Isles. Between two and three thousand records were sent in, showing the number of days on which thunder or lightning was reported from each country, between Jan. 1 and Mar. 31, 1926, to be as follows:

1926	England and Wales.	Scotland.	Ireland.	British Isles.
January . .	17	4	15	21
February . .	11	6	5	13
March . .	9	11	6	15
Totals (3 months)	37	21	26	49

The figure—49 days—for the British Isles is eight days less than that obtained during the same period in 1925. The number of days for Scotland and Ireland is very probably too low, on account of the small numbers of observers in those parts.

In England and Wales there were four very prominent stormy areas: one of these was in south-west Yorkshire and south Lancashire, and another was the district round the Severn Estuary. There was a belt of country free from storms in the Midland counties: a similar feature has been noticed in previous winters.

The investigation is being continued during the present season, and I shall be very grateful for reports of any thunder or lightning which may be observed by readers of NATURE before April 1 next. A note of the place, date, and time of the occurrence, with the direction in which the lightning is seen, especially at night, will be very valuable. Any additional information of the following character will be welcome:

1. The time when the storm passed overhead, or was nearest, with its direction; how long it lasted.
2. Severity of storm; much or little thunder, or lightning.
3. Whether it was accompanied by rain, hail, or snow.
4. Direction and strength of wind; change of wind (if any).
5. Whether there was a change in temperature during the storm.

S. MORRIS BOWER.

Langley Terrace,
Oakes, Huddersfield, Jan. 8.

The Infra-Red Spectrum of Hydrogen.

IN view of the considerable attention given to the secondary spectrum of hydrogen in recent investigations, it may be worth announcing that this spectrum has been extended photographically so far as 9300 Å.U. into the infra-red. Neocyanin plates were used, hypersensitised by an ammonia bath. About 170 additional lines to those recently published by Allibone (*Proc. Roy. Soc. A.*, 112, 196, 1926) were measured, about 120 of these being above his uppermost limit. Some of the more intense lines beyond the highest values hitherto published are (Int. Å.U. vac.):

9161·9
8970·3
8901·3
8878·5
8810·2
8797·6
8749·6
8726·8
8673·4
8666·6
8586·9
8577·5
8548·8
8538·1
8530·7
8522·9
8488·6
8446·6
8400·9
8369·5

Since dispersion was sacrificed for the sake of intensity in this preliminary work, these values may be in error by several tenths of an angström. The work is to be repeated under higher dispersion.

By altering conditions of the discharge to obtain a practically pure monatomic spectrum, five higher members of the Paschen series, the fourth to the eighth inclusive, were obtained photographically. Their measured wave-lengths agree with the values calculated according to the Bohr formula to within the limits of experimental error. The wave-lengths are (Int. Å.U. in air):

Line.	Observed λ.	Calculated λ.
P_δ	10049·8	10049·5
P_ϵ	9546·2	9546·0
P_ζ	9229·7	9229·1
P_η	9015·3	9014·9
P_θ	8863·4	8862·9

Lengthened Chain Compounds of Sulphur.

Dr. G. M. Bennett, in comments on a note on the above subject published in Nature (Oct. 16, 1926, p. 555), questions the purity of the compounds of the type $Br . C_2H_4(S . C_2H_4)_nBr$ obtained by the interaction of dithioethylene glycol and ethylene dibromide. From a consideration of melting-points some of the lower homologues may be regarded as 'impure,' but it should be borne in mind that the presence of minute traces of impurities would raise or depress their melting-point, but all the same, analyses of the compounds would establish definite composition. This does not, however, apply to the case of $Br . C_2H_4(S . C_2H_4)_{46}Br$. The preparation of this compound was repeated at least two dozen times under the experimental conditions detailed in the original paper, and the melting-point and analytical results agreed remarkably well. Moreover, it retained, even on crystallisation from molten naphthalene, the same melting-point and composition. These facts are sufficient to justify our claims to the purity of the compound. Further, the suggestion of Dr. Bennett that the compound might be contaminated with "substances some of which do not contain bromine," is rather doubtful in view of the fact that non-brominated substances could not be found after the disruption of the molecule by ethylene dibromide.

In conclusion, I may point out that chain compounds of sulphur having high molecular weights and definite structures are but few. Ray and Guha (*J. Chem. Soc.*, 115, 547, 1919) obtained a chain compound of (sulphonium) sulphur having so high a molecular weight as 3472.

Tuning-Forks with Parallel Prongs.

When the butt end of a vibrating tuning-fork is placed on a table, the fork will give out, under certain conditions, in addition to its fundamental, a note which is of frequency one octave higher than the note heard when the fork is held to the ear. This fact has been stated by Ellis (Helmholtz, "The Sensations of Tone" second English edition, p. 54), but apparently no explanation has been put forward.

That the effect is to be expected on theoretical grounds may be made clear by considering a fork with two parallel prongs. When the fork vibrates the prongs oscillate on either side of the mean position, and they pass through the parallel position *twice* during each complete vibration. If the fork were freely suspended the centre of mass would not move, and therefore the butt would be at its maximum displacement whenever the prongs are parallel. Consequently the octave should be present when the butt of the fork is pressed against the table. Most forks do not show this effect, as they are constructed with their prongs inclined at a small angle to each other. Therefore when they are set in vibration the prongs never reach the parallel position, and the octave is not present.

At the suggestion of Dr. L. F. Richardson an experiment was made on a tuning-fork with prongs inclined outwardly, which did not previously show the effect. The steel of the fork was softened and the prongs were put in a vice, so that they could be bent into any desired position. It was found that the octave was not present when the prongs were inclined either towards or away from each other, but occurred very markedly when they were made parallel. It was also noticed that the octave was most pronounced for large amplitudes and gradually died away as the amplitude decreased, leaving only the fundamental present.

Polar Pressures.

As I happen to be the author of a sentence quoted by Prof. Hobbs (Nature, Dec. 25, p. 915) from a review in the *Geographical Journal* (Sept. 1926) of his recent book on the glacial anticyclones, may I be permitted to point out that an essential word is omitted from the quotation and that Prof. Hobbs thus misrepresents what I wrote. My full statement was this: "Prof. Hobbs seems to think that the observational evidence fails to warrant the prevalent idea that there are vast circum-polar cyclonic whirls, which he is unable apparently to co-ordinate with his Antarctic glacial anticyclone. Yet in a masterly analysis Dr. Jeffreys has recently demonstrated (*Q. J. R. Met. Soc.*, vol. 52, p. 85) that whatever superficial increase of pressure there may be over either pole, or over Greenland, in consequence of the cold, this is a shallow surface effect; and that both poles are fundamentally seats of low pressure."

By the omission of the word *fundamentally* from the quotation, Prof. Hobbs deprives my sentence of the power to indicate the very co-ordination which I hold him to be incapable of effecting. The high pressures of the glacial anticyclones of Antarctica and Greenland, and of the North Polar wind-divide, are relatively slight, as Prof. Hobbs himself apparently allows, and can be reconciled with circum-polar low pressure at higher levels, for which there is a good deal of evidence apart from any theoretical considerations. The rest of the matter I leave to Dr. Jeffreys as more immediately concerned.

A Dynamical Theory of the Electromagnetic Field.[1]

THE proposed Theory seeks for the origin of electromagnetic effects in the medium surrounding the electric or magnetic bodies, and assumes that they act on each other not immediately at a distance, but through the intervention of this medium.

The existence of the medium is assumed as probable, since the investigations of Optics have led philosophers to believe that in such a medium the propagation of light takes place.

The properties attributed to the medium in order to explain the propagation of light are—

1st. That the motion of one part communicates motion to the parts in its neighbourhood.

2nd. That this communication is not instantaneous but progressive, and depends on the elasticity of the medium as compared with its density.

The kind of motion attributed to the medium when transmitting light is that called transverse vibration.

An elastic medium capable of such motions must be also capable of a vast variety of other motions, and its elasticity may be called into play in other ways, some of which may be discoverable by their effects.

One phenomenon which seems to indicate the existence of other motions than those of light in the medium, is that discovered by Faraday, in which the plane of polarisation of a ray of light is caused to rotate by the action of magnetic force. Professor W. Thomson[2] has shown that this phenomenon cannot be explained without admitting that there is motion of the luminiferous medium in the neighbourhood of magnets and currents.

The phenomena of electromotive force seem also to indicate the elasticity or tenacity of the medium. When the state of the field is being altered by the introduction or motion of currents or magnets, every part of the field experiences a force, which, if the medium in that part of the field is a conductor, produces a current. If the medium is an electrolyte, and the electromotive force is strong enough, the components of the electrolyte are separated in spite of their chemical affinity, and carried in opposite directions. If the medium is a dielectric, all its parts are put into a state of electric polarization, a state in which the opposite sides of every such part are oppositely electrified, and this to an extent proportioned to the intensity of the electromotive force which causes the polarization. If the intensity of this polarization is increased beyond a certain limit, the electric tenacity of the medium gives way, and there is a spark or " disruptive discharge."

Thus the action of electromotive force on a dielectric produces an electric displacement within it, and in this way stores up energy which will reappear when the dielectric is relieved from this state of constraint.

A dynamical theory of the Electromagnetic Field must therefore assume that, wherever magnetic effects occur, there is matter in motion, and that, wherever electromotive force is exerted, there is a medium in a state of constraint; so that the medium must be regarded as the recipient of two kinds of energy—the actual energy of the magnetic motion, and the potential energy of the electric displacement. According to this theory we look for the explanation of electric and magnetic phenomena to the mutual actions between the medium and the electrified or magnetic bodies, and not to any direct action between those bodies themselves.

In the case of an electric current flowing in a circuit A, we know that the magnetic action at every point of the field depends on its position relative to A, and is proportional to the strength of the current. If there is another circuit B in the field, the magnetic effects due to B are simply added to those due to A, according to the well-known law of composition of forces, velocities, &c. According to our theory, the motion of every part of the medium depends partly on the strength of the current in A, and partly on that in B, and when these are given the whole is determined. The mechanical conditions therefore are those of a system of bodies connected with two driving-points A and B, in which we may determine the relation between the motions of A and B, and the forces acting on them, by purely dynamical principles. It is shown that in this case we may find two quantities, namely, the " reduced momentum " of the system referred to A and to B, each of which is a linear function of the velocities of A and B. The effect of the force on A is to increase the momentum of the system referred to A, and the effect of the force on B is to increase the momentum referred to B. The simplest mechanical example is that of a rod acted on by two forces perpendicular to its direction at A and at B. Then any change of velocity of A will produce a force at B, unless A and B are mutually centres of suspension and oscillation.

Assuming that the motion of every part of the electromagnetic field is determined by the values of the currents in A and B, it is shown—

1st. That any variation in the strength of A will produce an electromotive force in B.

2nd. That any alteration in the relative position of A and B will produce an electromotive force in B.

3rd. That if currents are maintained in A and B, there will be a mechanical force tending to alter their position relative to each other.

4th. That these electromotive and mechanical forces depend on the value of a single function M, which may be deduced from the form and relative position of A and B, and is of one dimension in space; that is to say, it is a certain number of feet or metres.

The existence of electromotive forces between the circuits A and B was first deduced from the fact of electromagnetic attraction, by Professor Helmholtz[3] and Professor W. Thomson,[4] by the principle of the Conservation of Energy. Here the electromagnetic attractions, as well as the forces of induction, are deduced from the fact that every current when established in a circuit has a certain persistency or momentum—that is, it requires the continued action of an unresisted electromotive force in order to alter its value, and that this "momentum" depends, as in various mechanical problems, on the value of other currents as well as itself. This momentum is what Faraday has called the Electrotonic State of the circuit.

---

[1] Abstract of a paper by Prof. J. Clerk Maxwell communicated to the Royal Society on Oct. 27, 1864. Reprinted from the Proceedings of the Society, vol. 13, p. 531, Dec. 8, 1864.

[2] Proceedings of the Royal Society, June 1856 and June 1861.

It may be shown from these results, that at every point in the field there is a certain direction possessing the following properties:—

A conductor moved in that direction experiences no electromotive force.

A conductor carrying a current experiences a force in a direction perpendicular to this line and to itself.

A circuit of small area carrying a current tends to place itself with its plane perpendicular to this direction.

A system of lines drawn so as everywhere to coincide with the direction having these properties is a system of lines of magnetic force; and if the lines in any one part of their course are so distributed that the number of lines enclosed by any closed curve is proportional to the "electric momentum" of the field referred to that curve, then the electromagnetic phenomena may be thus stated:—

The electric momentum of any closed curve whatever is measured by the number of lines of force which pass through it.

If this number is altered, either by motion of the curve, or motion of the inducing current, or variation in its strength, an electromotive force acts round the curve and is measured by the decrease of the number of lines passing through it in unit of time.

If the curve itself carries a current, then mechanical forces act on it tending to increase the number of lines passing through it, and the work done by these forces is measured by the increase of the number of lines multiplied by the strength of the current.

A method is then given by which the coefficient of self-induction of any circuit can be determined by means of Wheatstone's electric balance.

The next part of the paper is devoted to the mathematical expression of the electromagnetic quantities referred to each point in the field, and to the establishment of the general equations of the electromagnetic field, which express the relations among these quantities.

The quantities which enter into these equations are:—Electric currents by conduction, electric displacements, and Total Currents; Magnetic forces, Electromotive forces, and Electromagnetic Momenta. Each of these quantities being a directed quantity, has three components; and besides these we have two others, the Free Electricity and the Electric Potential, making twenty quantities in all.

There are twenty equations between these quantities, namely Equations of Total Currents, of Magnetic Force, of Electric Currents, of Electromotive Force, of Electric Elasticity, and of Electric Resistance, making six sets of three equations, together with one equation of Free Electricity, and another of Electric Continuity.

These equations are founded on the facts of the induction of currents as investigated by Faraday, Felici, &c., on the action of currents on a magnet as discovered by Oersted, and on the polarization of dielectrics by electromotive force as discovered by Faraday and mathematically developed by Mossotti.

An expression is then found for the intrinsic energy of any part of the field, depending partly on its magnetic, and partly on its electric polarization.

From this the laws of the forces acting between magnetic poles and between electrified bodies are deduced, and it is shown that the state of constraint due to the polarization of the field is such as to act on the bodies according to the well-known experimental laws.

It is also shown in a note that, if we look for the explanation of the force of gravitation in the action of a surrounding medium, the constitution of the medium must be such that, when far from the presence of gross matter, it has immense intrinsic energy, part of which is removed from it wherever we find the signs of gravitating force. This result does not encourage us to look in this direction for the explanation of the force of gravity.

The relation which subsists between the electromagnetic and the electrostatic system of units is then investigated, and shown to depend upon what we have called the Electric Elasticity of the medium in which the experiments are made (*i.e.* common air). Other media, as glass, shellac, and sulphur have different powers as dielectrics; and some of them exhibit the phenomena of electric absorption and residual discharge.

It is then shown how a compound condenser of different materials may be constructed which shall exhibit these phenomena, and it is proved that the result will be the same though the different substances were so intimately intermingled that the want of uniformity could not be detected.

The general equations are then applied to the foundation of the Electromagnetic Theory of Light.

Faraday, in his "Thoughts on Ray Vibrations,"[5] has described the effect of the sudden movement of a magnetic or electric body, and the propagation of the disturbance through the field, and has stated his opinion that such a disturbance must be entirely transverse to the direction of propagation. In 1846 there were no data to calculate the mathematical laws of such propagation, or to determine the velocity.

---

[3] Conservation of Force. Berlin, 1847: translated in Taylor's Scientific Memoirs, Feb. 1853, p. 114.

[4] Reports of British Association, 1848. Phil. Mag. Dec. 1851.

[5] Phil. Mag. 1846. Experimental Researches, vol. iii. p. 447.

The equations of this paper, however, show that transverse disturbances, and transverse disturbances only, will be propagated through the field, and that the number which expresses the velocity of propagation must be the same as that which expresses the number of electrostatic units of electricity in one electromagnetic unit, the standards of space and time being the same.

The first of these results agrees, as is well known, with the undulatory theory of light as deduced from optical experiments. The second may be judged of by a comparison of the electromagnetical experiments of Weber and Kohlrausch with the velocity of light as determined by astronomers in the heavenly spaces, and by M. Foucault in the air of his laboratory.

Electrostatic units in an electromagnetic unit . .	310,740,000 metres per second.
Velocity of light as found by M. Fizeau	314,858,000.
Velocity of light by M. Foucault	298,000,000.
Velocity of light deduced from aberration . . .	308,000,000.

At the outset of the paper, the dynamical theory of the electromagnetic field borrowed from the undulatory theory of light the use of its luminiferous medium. It now restores the medium, after having tested its powers of transmitting undulations, and the character of those undulations, and certifies that the vibrations are transverse, and that the velocity is that of light. With regard to normal vibrations, the electromagnetic theory does not allow of their transmission.

What, then, is light according to the electromagnetic theory? It consists of alternate and opposite rapidly recurring transverse magnetic disturbances, accompanied with electric displacements, the direction of the electric displacement being at right angles to the magnetic disturbance, and both at right angles to the direction of the ray.

The theory does not attempt to give a mechanical explanation of the nature of magnetic disturbance or of electric displacement, it only asserts the identity of these phenomena, as observed at our leisure in magnetic and electric experiments, with what occurs in the rapid vibrations of light, in a portion of time inconceivably minute.

This paper is already too long to follow out the application of the electromagnetic theory to the different phenomena already explained by the undulatory theory. It discloses a relation between the inductive capacity of a dielectric and its index of refraction. The theory of double refraction in crystals is expressed very simply in terms of the electromagnetic theory. The non-existence of normal vibrations and the ordinary refraction of rays polarized in a principal plane are shown to be capable of explanation; but the verification of the theory is difficult at present, for want of accurate data concerning the dielectric capacity of crystals in different directions.

The propagation of vibrations in a conducting medium is then considered, and it is shown that the light is absorbed at a rate depending on the conducting-power of the medium. This result is so far confirmed by the opacity of all good conductors, but the transparency of electrolytes shows that in certain cases vibrations of short period and amplitude are not absorbed as those of long period would be.

The transparency of thin leaves of gold, silver, and platinum cannot be explained without some such hypothesis.

The actual value of the maximum electromotive force which is called into play during the vibrations of strong sunlight is calculated from Pouillet's data, and found to be about 60,000,000, or about 600 Daniell's cells per metre.

The maximum magnetic force during such vibrations is ·193, or about $\frac{1}{10}$ of the horizontal magnetic force at London.

Methods are then given for applying the general equations to the calculation of the coefficient of mutual induction of two circuits, and in particular of two circles the distance of whose circumferences is small compared with the radius of either.

The coefficient of self-reduction of a coil of rectangular section is found and applied to the case of the coil used by the Committee of the British Association on Electrical Standards. The results of calculation are compared with the value deduced from a comparison of experiments in which this coefficient enters as a correction, and also with the results of direct experiments with the electric balance.

The Induction of Melanism in the Lepidoptera, and its Evolutionary Significance.

By Dr. J. W. Heslop Harrison.

In recent years no more remarkable evolutionary phenomenon has been observed than the development and progress of melanism amongst British native Lepidoptera. Species after species of moth with pale ground colour has given rise to forms so heavily pigmented that they appear in some cases to be dark grey and in others perfectly black. Further, the course of events has not ended with the mere appearance of these melanic forms; in affected species a state of equilibrium has only been attained in the areas concerned when the whole of their representatives has assumed the melanic guise. On Tyneside, for example, twenty-five years ago the species *Boarmia repandata* (the Mottled Beauty) was quite typical; now every specimen captured is black. Moreover, the advance of this progressive melanism is not stayed locally, for new species fall under its influence every year, the latest to yield being *Phigalia pedaria* (the Pale Brindled Beauty) and *Tephrosia bistortata* (the Engrailed).

Clearly, in the development of these melanic insects we are concerned with a very noteworthy phase of evolutionary activity—noteworthy because it is taking place before our eyes. But the importance of the phenomenon does not rest here; no matter what attempts are made to minimise the connexion, it cannot be denied that upon the industrialisation of the affected area depends the incidence of melanism, or, in other words, the two are related in the way of cause and effect. Thus we are dealing with a case of evolution directed by the environment, and presumably, therefore, of the Lamarckian order.

Naturally, this view has been strongly contested by the opponents of the Lamarckian position, but, let it be emphasised, not one of those so opposed has studied the subject in the field. On the other hand, field workers are unanimous in giving it vigorous support.

At first it was the practice amongst the anti-Lamarckians, in their endeavours to explain it away, to point triumphantly to the absence of melanism in continental industrial areas, and then, when in the end such localities did provide melanic species, to account for them on the basis of chance importations from England. However, the advent of melanic varieties of species like *Cymatophora or* (the Poplar Lutestring) and *Boarmia roboraria* (the Great Oak Beauty) on the Continent, prior to their appearance in Britain (an occurrence depending simply on the fact that the species in question do not approach the smoke zones in Britain as they do in Germany), rendered this position untenable, and a new line of defence was forthwith constructed. Appeal was now made to the failure of melanic forms in the manufacturing districts of the United States. Again the irresistible weight of facts broke down the defence, for the very first species to 'go black' in England, the Peppered Moth (*Amphidasys betularia*—known in America as *Lycia cognataria*), did the same at Pittsburg. Nor is this an isolated case, for in America Holarctic species like *Tephrosia crepuscularia* (the Small Engrailed), already melanic in Europe, with typically Nearctic forms like *Phigalia titea*, have succumbed to the same influence, to be followed assuredly by many others.

Hence, whether we like it or not, the dependence of melanism on industrialisation must be granted.

With the recognition of this fact, field workers and others very early indeed began to construct theories to explain it, cold, humidity, smoke, soil, and light deficiency all being invoked as inciting agents, either in the crude form of a prime cause or as cogs in a more complex mechanism. The inadequacy of such theories, even when supplemented by natural selection, has already been demonstrated by me in an early[1] paper. In their stead, in the same publication, an alternative suggestion was put forward that metallic salts ingested with the larval food of affected species might so act directly on their germplasm as to alter its potentialities. If such a belief was correct it seemed an easy matter to devise conclusive tests of its validity.

By direct analysis of the deposits on the foliage of trees in Middlesbrough Park, it was discovered that they contained relatively large quantities of salts of manganese, iron, sodium, potassium, and other metals. Furthermore, investigations as to the manganese content of hawthorn leaves near Newcastle-upon-Tyne revealed the presence of unusual percentages of that metal, with a progressive diminution as we passed westward into rural areas.

From these, and other considerations arising out of the peculiar properties of the oxides of manganese, it was determined to supply the larvæ of carefully selected species from nonmelanic regions with food (1) artificially charged with small percentages of manganese compounds, or (2) so contaminated by having been grown within the limits of a smoky manufacturing town. In addition, it was decided to supplement the manganese cultures with parallel ones in which lead salts were employed, the exact salts utilised in the two cases being manganese sulphate and lead nitrate.

Suitable species for the investigations were found in *Tephrosia bistortata*, *T. crepuscularia*, *Selenia bilunaria* (the Early Thorn), and *S. tetralunaria* (the Purple Thorn), all of which under experimental conditions gave rise to melanic individuals. Nevertheless, by far the most important and exhaustive work[2] was carried out with southern strains of *S. bilunaria* and *T. bistortata*.

In the case of *S. bilunaria*, melanics appeared both in the lead and the manganese cultures, the critical lead broods yielding three melanics and fifty-three types and the manganese brood eight melanics and twelve types; the controls from the same source provided nothing but types.

This induction of melanism had, of course, but little significance unless the melanism was inherited, and in each of these cases, to test this, since melanics of the opposite sexes failed to synchronise in emergence, melanics were paired with types.

The F_1 batches so reared in the lead series, supplied, of course, with untreated food, contained 26 insects, all quite typical; obviously, if inherited at all, the melanism was acting as a Mendelian recessive. Inbreeding the F_1 insects provided three F_2 batches containing a total of 70 types and 23 melanics—a ratio of 3·04 : 1, which approximates exceedingly closely to the expected ratio of 3 :1.

Similarly, the F_1 manganese family contained only typical insects which, inbred to secure the critical F_2 lots, gave two broods composed of 90 types and 27 melanics—a ratio of 3·3 : 1, again suggesting that melanism was inherited as a Mendelian recessive.

Various matings designed to confirm this were made, with the outcome that, totalling all the figures pertinent to the inquiry, it was found that four families bred from the pairing of homozygous type and homozygous melanic yielded 230 types and 0 melanics, three from heterozygous type × homozygous melanic giving 93 types and 77 melanics, seven from heterozygous type × heterozygous type 363 types and 105 blacks, seven from homozygous blacks mated *inter se* 316 blacks and 2 types, and finally, two families of the origin homozygous type × heterozygous type included 132 types, all of which results lead to the same conclusion.

---

[1] Harrison, "Genetical Studies in the Moths of the Geometrid Genus Oporabia, with a Special Consideration of Melanism in the Lepidoptera," *Jour. Genet.*, vol. 9, 1920.

[2] Harrison and Garrett, "The Induction of Melanism in the Lepidoptera and its Subsequent Inheritance," *Proc. Roy. Soc.* B, vol. 99, 1926.

With the results, those secured in the *T. bistortata* work were in perfect agreement—a rather unexpected fact, for, in the Boarmiinae, including the allied *T. crepuscularia*, the melanism, whether induced or natural, is always a Mendelian dominant.

As stated in the concluding remarks of the Royal Society paper (Harrison and Garrett), this work left undecided the question whether it was the metal or the acid radical which played the active part. To determine this, additional work was undertaken with a Saxon strain of *Selenia bilunaria*. This strain, after five inbred generations reared on food charged with manganese chloride, has just (Dec. 19, 1926) supplied three female insects, two types and one melanic, a further induction of melanism rendering it probable that it is to the metal that we have to look for the inciting agent.

No matter what the exact meaning of these experiments, they demonstrate, without any possibility of contradiction, that the germplasm can be influenced by external agencies; therefore, if not of direct Lamarckian import, they lend weighty support to Lamarckian views, for what is in more intimate contact, chemically or otherwise, with the germplasm than the soma?

Irrespective of this, they supply, what evolutionary theories all lack, an experimental demonstration of at least one cause of variation; in fact, they go beyond this, for they actually provide the principle, new in evolution, that food not normal to any given organism may so affect its germplasm as to give rise to heritable variations. This being granted, we see at once how a change in habitat can originate new forms and finally new species.

In no group of organisms would this be more potent than in plants, and thus, instead of an appeal to the sorting out of various genotypes as urged by Turesson [3] to account for the existence of localised genotypes in various plant species, we can conceive of their origin in the stations in which they now exist. So, too, in the variation of cultivated plants influences of the same order are at work.

Nor are animals in Nature exempt from its operations; local races of animals, under the workings of this principle, find a ready explanation, and so do the various forms into which wild animals break when domesticated. In no group of animals are its workings so beautifully illustrated than in the Insecta, particularly in the phytophagous groups.

Often enough, owing to the preference of plants to grow in definite associations, different species of plants grow intermingled. What then is more likely than the accidental transference of eggs or larvæ to the wrong foodplant? Is not the difference between species chemical? If larvæ so transferred react as in the experimental work, new [4] phytophagous races or species must arise, isolated by their attachment to a special foodplant, and induced to vary from the type from which they were derived by the influence, exerted chemically, of that foodplant. Of insects so related to one another, even in our own restricted fauna, we have many; for example, the moth *Cerura bicuspis* is purely an alder feeder, whilst its congener *C. furcula* takes sallow, the Aleurodid *Tetralicia vaccinii* feeds on bilberry, and *T. ericae* on *Erica tetralix*, the gall-gnat *Loewiola centaureae* parasitises *Centaurea nigra* and its relative *L. serratulae*, *Serratula tinctoria*, and so the list could be extended to all insect groups.

[4] As demonstrated by me in the case of the Gallmaking sawflies of the genus Pontania in a paper now in the press.

Electro-deposition of Rubber.

FROM recent announcements in the press it would appear that some considerable changes are likely to take place in the technology of rubber as the outcome of patented developments in the process of rubber electro-deposition. So promising have been the results obtained that the American rights in the various patents concerned have been transferred from their original owners, the Anode Rubber Co. of Great Britain, the B. F. Goodrich Rubber Co., and the Eastman Kodak Co., to a new company called the American Anode, Inc., for independent exploitation. The British rights, it is understood, have just been acquired by the Dunlop Rubber Co. and its associated concerns. It is perhaps too soon yet to estimate the commercial value of the whole process, for it can only be regarded as emerging from the experimental stage; but the fact that strong financial support is already forthcoming furnishes presumptive evidence of its value.

The possibility of rubber electro-deposition dates back to 1906, when Henri observed that in rubber latex, which is a colloidal suspension of rubber particles in a serum, the particles are negatively charged and migrate to the anode under the influence of a direct-electric current. The observation found early practical application in Cockerill's process, patented in 1908, for removing rubber from latex by depositing it electrically upon a moving anode; but as this process led only to the production of crude rubber—in fact it was only intended for the coagulation of rubber from latex prior to shipment—its commercial scope was limited. The importance of the recent developments in this field arises from the discovery, made independently in 1922–23 by Klein in Hungary and by Sheppard and Eberlin in the United States, that all the ingredients essential to the production of finished rubber articles, namely, the sulphur required for vulcanisation purposes, many fillers and other compounding ingredients, as well as organic dyes and vulcanisation accelerators, can be admixed in a finely divided state with rubber latex or even with an artificial dispersion of rubber, and that the whole adsorption compound produced can be electrically precipitated as a homogeneous layer on the anode which serves as a mould. It then only remains to vulcanise the deposit in the usual way, either after separation from the metallic surface or while still adhering thereto. Of course it may not be desirable to add the vulcanising agent to the bath, but to effect a cold vulcanisation after deposition. In fact, as may be gathered from the patent literature on the subject, the process is capable of many modifications.

It will be evident that the process which has been outlined eliminates many of the cumbersome mechanical methods at present associated with the rubber industry. The operating conditions can be precisely controlled, whilst by maintaining them constant the process can be made continuous or even automatic; moreover, being a cold process throughout, the original quality and structure of the starting material are retained in the product. Against these advantages must be set the fact that, since rubber is a non-conductor, it is possible to obtain only comparatively thin sheets of rubber product, though further investigation will doubtless remove this limitation. The oxygen liberated by electrolysis at the anode gives rise to a further difficulty, inasmuch as it leads to the formation of a spongy deposit; already, however, many proposals have been made for overcoming this defect, such as the use of porous moulds surrounding the anode or the addition of reducing agents to the bath. When the technique of the process has been perfected, a reduction in the cost of manufacture of sheet rubber goods and rubbered fabrics may be anticipated; not only that, but important developments may be expected in the direction of the coating of metal and other surfaces with rubber.

Obituary.

SIR JOHN SCOTT KELTIE.

SIR JOHN KELTIE seemed endowed with perpetual youth. He regulated his activities so nicely to his increasing age that, even when well advanced in his eighty-seventh year, he was able in one day to lunch at his club, attend a long committee meeting and the Council of the Royal Geographical Society, conduct a dinner of the Geographical Club, sit through a long evening meeting of the Society, seeing and hearing everything as clearly as when a boy, and, after returning home, sit up until midnight talking over the past and planning the future for a year or two ahead. He found life so full of interest and satisfaction that there seemed no reason why he should not live to celebrate the centenary of the Royal Geographical Society in 1930, and that of his own birth in 1940. He was happy in being spared the suffering of long illness and the dulling of his physical powers; he died of bronchitis on Wednesday, Jan. 12, at work almost to the last day.

Keltie was born in Dundee on Mar. 29, 1840, inheriting from his ancestors, who dwelt in Glendevon, a store of bodily health and mental fitness, but nothing more. Unaided and self-supporting, he made his way through several sessions, first at the University of St. Andrews and then at that of Edinburgh, though without taking a degree. The choice of a career seemed to lie between the dominie's desk and the preacher's pulpit, and he qualified himself for the latter in the United Presbyterian Church. But the narrow theology of the time repelled Keltie, and he used to tell how many years later he looked up the "Year-Book" of his old Church and found his name branded with the curt comment, "Lapsed into literature."

Keltie's literary work began in 1861 with Messrs. W. and R. Chambers in Edinburgh, who were then publishing the first edition of their famous "Encyclopædia," and at this period he produced many pieces of work in various fields, including a "History of the Highland Clans." He married in 1865, and soon found life in Edinburgh too narrow for his ambition. The southing instinct of his race brought him to London in 1871, when he joined the editorial staff of Messrs. Macmillan and Co., Ltd., and remained in association with that firm to the end of his life. He acted as sub-editor of NATURE from 1873 until 1885, and as editor of the "Statesman's Year-Book" from 1880 until his death, this being the last of his literary activities and that of which he was most proud. In 1873 he wrote an article on the island of Socotra and sent it at a venture to the *Times*, which accepted it, and thus began a lifelong association with that journal. It was probably this chance which turned his attention seriously to geography in time to share in all the stirring episodes of the opening up of Africa, the penetration of central Asia, and the polar expeditions of forty remarkable years. His work on NATURE similarly developed in him a wide knowledge of the literature of science and a keen though unspecialised interest in its advances.

Keltie joined the Royal Geographical Society as a fellow in 1883, and in the following year when the Society was roused, at the instance of Mr. D. W. Freshfield, to deal with educational aspects, he was appointed inspector of geographical education and commissioned to inquire into the methods of teaching in Great Britain and abroad. On this service Keltie travelled through the principal countries of Europe and brought home a very large collection of text-books, maps, and teaching appliances which he exhibited and lectured upon in London, Edinburgh, and other places. He produced a valuable report setting forth the deplorable state of geographical teaching in the British Isles as compared with France, Germany, and Italy. From this report sprung directly the revival in teaching geography which has culminated in the training and appointment of professors or readers in every British University and the institution of a geographical tripos at Cambridge. In 1894 the librarianship of the Royal Geographical Society became vacant and Keltie was appointed to the post, then a part-time occupation, which afforded great opportunities for the pursuit of private literary work. Keltie soon became the indispensable helper of the assistant secretary—the great naturalist H. W. Bates, whom he succeeded in the secretaryship in 1892. From this time onward the administrative work of the Society engrossed his attention and could well have filled the whole time of a less untiring worker than Keltie; but it only stimulated his literary and journalistic powers and, at a time when the science of publicity was still imperfectly developed, his connexion with the press did much to enhance the prestige and popularity of the Society and the fame of the great travellers and explorers with whom he was in daily contact.

Throughout his work at the Royal Geographical Society Keltie was on the side of progress, always encouraging those who were striving after more scientific methods in exploration or discussion and always interposing a moderate but unwavering opposition to reactionary tendencies. The confidence which successive presidents and councillors reposed in his judgment made him a power in the Society and in the geographical world even in his days of silent service as secretary. After he retired from the secretaryship in 1917, he was elected to the Council and latterly acted as vice-president.

Keltie was long connected with Section E of the British Association, in which he was recorder for several years and president at the Toronto meeting of 1897; afterwards he served on the Council of the Association. He bore the lion's share of the organisation of the great International Geographical Congress of London in 1895 and was one of the secretaries at the meeting. He also supported the Geographical Association from its day of small things and helped it forward to its present splendid maturity.

Although most of his work is likely to be forgotten as journalism, much of it ranks as literature and is of more than ephemeral interest, especially his "Partition of Africa"—a study of political geography in the making—and his "Applied Geography." He initiated and edited several important series of books on travel and exploration either alone or in collaboration. In 1893 he reconstructed the serial publications of the Royal Geographical Society and made its monthly *Journal* the most popular as well as the most widely circulated paper of its kind in Europe, while at the same time maintaining to the full its scientific character and the high standard of its cartography. His skill as an editor was of a high order, and he excelled in the art of inducing difficult contributors to follow the rules.

Though no explorer and little of a traveller, Keltie exerted a powerful influence on exploration in every quarter of the globe by his close personal relations with travellers of every nationality during the last quarter of the nineteenth century and the first quarter of the twentieth. He had the quick intuition of the Highlander combined with the slow caution of the Lowlander and balanced by a tact and generalship peculiarly his own. While faithful to his superiors and to his subordinates alike, he never failed in the duty of giving sound even if unpalatable advice to the former, and he always treated the latter as fellow-workers and was scrupulously just in giving them credit for good intentions as well as good work. He attained great success in organising public ceremonial functions, and his private hospitality, aided by the charm of his daughter Mrs. T. L. Gilmour, will long be remembered.

The appreciation in which Sir John Keltie's work is held by those best qualified to judge it may be estimated from the honours he received. These include gold medals from the Geographical Societies of London, Edinburgh, Paris, and New York, the honorary membership of nearly all the geographical societies in the world, the honorary degree of LL.D. from St. Andrews, the companionship of several Scandinavian orders, and finally the honour of knighthood, which he received in 1918.

Hugh Robert Mill.

Dr. C. L. Withycombe.

Dr. Cyril Luckes Withycombe, lecturer in advanced and applied entomology, died at Cambridge on December 5, aged twenty-eight years. Born at Walthamstow, the son of a schoolmaster, he early developed a peculiar taste and power for the keeping and rearing of insects, and this indicated his career. He passed his Intermediate Science Examination from Birkbeck College, and then went on to King's College, where he came under the influence of the late Prof. Dendy and of Dr. Mackinnon, on whose advice, with the object of broadening his science, he took the ordinary degree in botany, chemistry, and zoology instead of honours in one subject. He then went to the Imperial College to work under the late Prof. Lefroy, who regarded him as by far the best pupil he ever had.

During these years Withycombe spent all his spare time in the field, and he kept and reared a large series of Neuroptera, on which group he published fourteen papers, the most important being on the biology of the group in reference to the phylogenetic significance of their immature stages (*Trans. Ent. Soc.*, 1923 and 1925). The phylogeny had already been discussed by Handlirsch on palæontological evidence, and by Tillyard and Comstock on external morphology and wing venation. While their work was fully considered, the result was a modestly written discussion of the relationships of the families together, summarised by the propounding of a new phylogenetic tree, based also on the mass of new facts discovered by the author; assuredly this paper marks a stage in the scientific history of the group. It is a pity that the task he had set himself of monographing the British species cannot be carried out.

In 1923 Dr. Withycombe went to Trinidad as lecturer in entomology at the newly founded Imperial College of Tropical Agriculture. He was happy in having agreeable colleagues, and in seeing the tropics and their produce. He described to me how his first year almost daunted him with his realisation of the insufficiency of present knowledge. It was clear he was passing through his transition period, blending what he knew of three sciences into one harmonious whole. It was at this time he published his work on the bladders of Utricularia, which as a boy he had independently discovered as capturing their prey by active movement in response to stimuli. His thought henceforth was of his plant first, and this is well seen in his research on the sugar-cane froghopper blight in Trinidad. Here he was dealing with a pest not introduced but belonging to the forests of the island, only secondarily attacking the canes. Having studied his insects and his plant together as one entity, his advice to the planter is to attend with the greatest care to his cultivation, in particular to see that his canes have plenty of water physiologically available for their growth. "Canes do not necessarily show serious blight when froghoppers have been abundant, nor is an abundance of the insect a necessary condition for serious blight." Other research in Trinidad resulted in the discovery of a bollworm, *Sacadodes pyralis*, a moth, the life history of which was worked out, and much time was spent in studying and rearing successive generations of cotton stainers, Dysdercus, bugs which prefer cotton to their natural Malvaceous plants and stain and rot the cotton lint by the bacteria and fungoid spores they introduce.

Dr. Withycombe only came to Cambridge in August last, and he at once set to work on his material of froghoppers and Dysdercus. He had to prepare a course of advanced lectures, and he had a sub-department to get into order. As a lecturer he was almost conversational, as he had seen everything of which he spoke, and his class loved him. As a colleague we admired and loved him too, for he had a most lovable personality, quite extraordinary vision, and absolute devotion to research. J. S. G.

MR. CHARLES HARDING, formerly an assistant in the Meteorological Office, died at Eastbourne on Sunday, Jan. 9, in his eighty-first year. Mr. Harding entered the Meteorological Department of the Board of Trade in 1861, and was among those who transferred to the service of the Meteorological Committee when the Office was reconstructed in 1867 after the death of Admiral Fitzroy. He thus had experience of the Office under all the different forms of administration through which it had passed, with the exception of the most recent one of all under the Air Ministry. For some thirty years Mr. Harding was Principal Assistant in the Marine Division, and served under three Marine Superintendents, Captain Toynbee, Lieutenant Baillie, and Captain M. W. Campbell Hepworth. He retired in 1911, but returned during the War for part-time duty, and did not finally sever his connexion with the Office until 1920. His active career in the Office, therefore, extended over nearly sixty years. Mr. Harding became a fellow of the Royal Meteorological Society in 1874, and served on its council and as vice-president for many years. He was the author of a number of meteorological papers, dealing mainly with climatology or marine meteorology, published in the *Proceedings of the Royal Meteorological Society* and elsewhere. For some forty years he was a valued and regular contributor of notes and articles on meteorological subjects to the columns of NATURE.

WE regret to announce the following deaths:

Dr. Daniel Carhart, professor emeritus of civil engineering since 1908 at the University of Pittsburgh, on Dec. 8, aged eighty-seven years.

Dr. Forris Jewett Moore, until a year ago professor of organic chemistry at the Massachusetts Institute of Technology, on Nov. 20, aged fifty-nine years.

Sir Isambard Owen, from 1909 until 1921 Vice-Chancellor of the University of Bristol, who took a leading part in the establishment of the University of Wales (1891–93) and in the reconstruction of the University of Durham (1907–9), on Jan. 14, aged seventy-six years.

Mr. F. J. Stoakley, for some fifty years chief assistant to the professor of chemistry at Cambridge, and well known to many generations of men who have worked in the Chemical Laboratory there, on Jan. 16, aged sixty-two years.

News and Views.

IN connexion with the reprint elsewhere in this issue (p. 125) of Clerk Maxwell's own abstract of his great memoir on the electrodynamic field, our attention has been directed by Sir Joseph Larmor to the valuable group of Maxwell letters that were discovered in 1903 among Stokes's private papers. They have been made public in the "Memoir and Scientific Correspondence of Sir George Stokes," vol. 2 (1907), pp. 1-45, published by the Cambridge University Press. They are an intimate account, reporting progress in a personal way from time to time in most of his scientific activity throughout his life. These and like collections of letters, from many of the most prominent workers of the time, all preserved by Stokes, make the two volumes an almost indispensable prolegomena to the history of discovery in physical science during the latter half of last century. A very interesting account of Maxwell's early years is contained in an obituary notice written by Tait for the Royal Society of Edinburgh, and printed in NATURE, vol. 21.

PROF. G. ELLIOT SMITH has announced in the *Times* of Jan. 14 an interesting discovery which he says "should settle once for all the century-old controversy regarding the identification of certain elephant-like creatures represented . . . in Mexico, Central America, and elsewhere in the New World." Mr. J. Eric Thompson has just discovered in the Ayer Collection of the Newberry Library in Chicago unpublished water-colour sketches made more than ninety years ago by M. Frédéric de Waldeck, a French artist, of four bas-reliefs in stucco found by himself on the floor of a subterranean room in the palace at Palenque, and also a drawing of a part of the wall in the same room. The drawings on the first of the stucco slabs show two elephant's heads drawn in a floral design which is said to be suggestive of motives of the Chinese T'ang period; the second shows anthropomorphised heads "of characteristic Maya style"; the third, a conventionalised tapir; and the fourth, an egg and Haliotis shell. The design on the sculptured wall represents an elephant's head, front face with open mouth, on a serpent's body, with a conventionalised macaw and tapir heraldically grouped on each side. Prof. Elliot Smith also publishes a photograph of a crudely modelled elephant from San Salvador and two views of a painted vase discovered in 1916, at Yalloch, Guatemala, the design on which is considered by Dr. Gann, the discoverer, to represent the long-nosed god B (the feathered serpent Cuculcan, the Aztec god Quetzalcoatl), but which Prof. Elliot Smith holds to represent the elephant in the conventionalised style of Java and Eastern Asia.

As readers of Nature are aware, Prof. Elliot Smith, reasoning as a zoologist, has argued ably that certain Maya sculptures represent the Indian elephant; but is it possible in so highly conventionalised an art as that of the Maya to make any attribution at all with certainty? The varied interpretations—tortoise, tapir, macaw, and the like—which provoke Prof. Elliot Smith's amusement, are evidence of the ambiguity of the design rather than of the perversity of the attempts at interpretation. The Waldeck drawings would place the matter beyond question if they could be accepted as accurate. Prof. Elliot Smith quotes vindications of Waldeck's trustworthiness, which had been impugned; but the drawings themselves show the influence of the pseudo-classical Empire style of the French art of Waldeck's day rather than the true spirit of Maya art. It is admitted that Waldeck had a penchant for restoration. In the circumstances, it is perhaps not too much to say that a stylised reproduction of a subject already highly conventionalised needs careful verification by experts before it can be accepted as evidence beyond question.

The Gold Medal of the Royal Astronomical Society has been awarded to Prof. Frank Schlesinger, of Yale University Observatory, for his work on stellar parallax and astronomical photography. Prof. Schlesinger has done excellent observational work in spectroscopy and the variation of latitude. Specially notable is his work on stellar parallax, in which he showed how a higher standard of accuracy was attainable and took a leading part in the organisation of a number of observatories in this work. He has recently established an observatory at Johannesburg for parallax observations in the southern hemisphere. He has also initiated the use of wide angle doublet lenses for determination of position. The great accuracy which he has attained has stimulated German astronomers to re-observe the Astronomische Gesellschaft Catalogue on these lines.

At its last meeting, the Council of the Royal Photographic Society awarded the Progress Medal to George Eastman "in recognition of his inventions, researches, publications, and other work," moved partly to this step by the broad vision displayed in his founding and supporting, alike with rich endowments and active co-operation, the Eastman Research Laboratories. From this organisation, staffed by some of the most notable scientific workers that photography can claim, reports concerned with almost every aspect of the subject, from theories of light action to the commonplaces of dark-room practice, are circulated freely without other tangible reward than the gratitude of practical workers. Mr. Eastman's labours in his chosen field stretch so far back as to be barely realised by the photographer of to-day. Fifty years ago, while still a youth, he worked out from scanty data gleaned in journals of the period a method of producing dry plates (then a novelty wholly imported from Europe) and courageously started their manufacture. The same qualities led him later to devote large sums and his great practical experience to perfecting the roll-holder, and its natural sequel the daylight-loading film camera of to-day. The zest with which he interested himself in the new product celluloid, and the whole-hearted support afforded Edison in his early work in kinematography, are mainly responsible for the rapid progress made by the latter towards mechanical precision. Had Friese Greene and Le Prince, working in England, enjoyed like access to this invaluable help in their hours of difficulty, few of the film problems now puzzling British Government departments need have arisen.

The friends and admirers of the late Dr. T. S. P. Strangeways are forming a memorial fund, of which the primary object will be the provision of scholarships for his five sons. The committee includes the Master of Christ's College, the Master of Gonville and Caius College, the Master of St. John's College, the Master of Trinity Hall, the Regius professor of physic, the professor of pathology, the professor of anatomy, Sir Otto Beit, Sir Walter Morley Fletcher, Sir Charles Walston, Lady Woodhead, Dr. Cassidy, and many other well-known names. Cheques should be crossed "c.a. Strangeways Memorial Fund," and may be sent to either of the hon. treasurers: Mr. G. F. C. Gill, Lloyds Bank, Cambridge, or Prof. Sir Humphry D. Rolleston, Bart., Southfield, Trumpington Road, Cambridge; or to Dr. L. E. Shore, Dr. Louis Cobbett, or Dr. G. P. Bidder. It is obvious that a large sum will be required; and towards this £1895 has been subscribed by the Committee and a few friends.

Among the men of science of the seventeenth century—a period made memorable by the work of Gilbert, Napier, Galileo, Wallis, Hooke, and Newton—the Hon. Robert Boyle will always occupy a prominent place. Born three hundred years ago, on Jan. 25, 1627, he might be called the Cavendish of his time.

Of noble birth, Boyle was left with ample means by a father who was one of the ablest of public men. The portrait of Boyle, however, is that of a thinker and not of a man of action. He was delicate and studious as a boy and owed much to his tutor, with whom he spent some years on the continent, while in after life he was influenced by his sister, just as Pascal was by his. It was in 1654 that Boyle, then twenty-eight years of age, went into residence at Oxford, and with Wilkins and others began those meetings which led to the foundation of the Royal Society. Six folio volumes tell of his industry, and contain the results of his experiments in chemistry and physics. Following in the footsteps of Torricelli and Otto von Guericke, he improved both barometer and air-pump, and it was in his "Defence of the Doctrine touching the Spring and Weight of Air," published in 1662, that he gave us the important law known by his name. He never held any appointment, though he might have been Provost of Eton and president of the Royal Society. His death took place on Dec. 30, 1691, just a week after that of his sister. They had long lived together in Pall Mall and were buried side by side "at the upper end of the south side of the chancel" of St. Martin-in-the-Fields; but thirty years later the church was rebuilt, and to-day no one can point to his grave and no monument recalls to the stranger that Boyle was buried there.

IN the *Sunday Times* of Jan. 2, Prof. H. J. Spooner directs attention to some of the notable centenaries which occur this year. Among the names of men of science which he mentions are those of Newton, Laplace, Fresnel, Volta, and Lister. The bi-centenary of the death of Newton will be celebrated at Grantham in March, while the centenary of the death of Volta is being recognised by the holding of an electrical exhibition at Como. The custom of commemorating such events should find general acceptance, for, as Fairbairn once remarked, "the smallest honour we can do the great benefactors of mankind is occasionally to bring them to our recollection." To the names mentioned many others might be added. Next in interest to mathematicians and astronomers, after Newton and Laplace, comes that of Robert Woodhouse (1773–1827), successively Lucasian professor and Plumian professor, to whom belongs the credit of introducing the calculus at Cambridge and who found earnest disciples in Babbage, Herschel, and Peacock. Another astronomer who died the same year was Calandrelli (1749–1827), once director of the Vatican Observatory, while going back four hundred years we have the birth of Stadius (1527–1579), a predecessor of Kepler as mathematician to the Emperor of Germany. A contemporary of Stadius who should not be overlooked was the famous Dr. John Dee, alchemist and astrologer, who was born in 1527 and died in 1608.

To chemists and physicists the tercentenary of the birth of Boyle (1627–1691) and the centenary of the death of Augustin Jean Fresnel (1788–1827) will afford the greatest interest. Though Fresnel sank into an early grave he was one of the foremost students of optics, and it was only eight days before his death that Arago placed in his hands the Rumford medal of the Royal Society. Another physicist of note who died in the same year was Chladni (1756–1827), whose works on sound were translated into French through Napoleon. Henry Beaufoy (1764–1827) was both physicist and astronomer but is still better known for his experiments in naval architecture. The year 1827 saw the publication by Ohm of "The Galvanic Circuit worked out mathematically". Although no great chemist died in 1827, in that year were born Sir Frederick Abel (1827–1902), John H. Gladstone (1827–1902), Edward Nicholson (1827–1890), and, most distinguished of all, Marcellin Berthelot (1827–1907). In the same year the death occurred of Samuel Crompton (1753–1827), whose work as the inventor of the spinning mule will be the occasion of a gathering at Bolton, and also of George Medhurst (1759–1827), one of the inventors of the atmospheric railway. Among the great pioneers of last century was Sandford Fleming (born 1827), who was Engineer-in-Chief of the Canadian Pacific Railway from 1871 until 1880.

SOME considerable stir in the United States was caused in July 1925 by the trial of Mr. John T. Scopes, a science teacher of a Tennessee high school, for having taught the truth of evolution in defiance of the State law. The matter aroused widespread interest, and in our issues of July 11 and later, we published the views of a number of leading men of science and theologians on the desirability or otherwise of the control of university and school curricula by the State. It will be recalled that Mr. Scopes was found guilty, after a long trial, of breaking the State laws and was fined 100 dollars. The defence at once announced its intention to appeal against the decision of the judge and to raise the question as to whether a State law prohibiting the teaching of evolution was consistent with the constitution of the United States. The case came before the Supreme Court of Tennessee, and on Jan. 15 the verdict was given that the 'anti-evolution' law is constitutional, but that the lower court erred in fining Mr. Scopes 100 dollars. Mr. Scopes was guilty of a misdemeanour, for which the maximum penalty in Tennessee, it would appear, is 50 dollars unless the case is tried by a jury.

ON Dec. 4 of last year, the twenty-fifth anniversary of the establishment of the Bureau of Standards was celebrated at Washington. The Hon. Herbert Hoover, Secretary of Commerce, and "the only Engineer in the Cabinet," delivered the first address, in the course of which he remarked: "The Bureau to-day represents the greatest of all the world's physical laboratories. . . . I know of no laboratory, no effort of any Government that represents so liberal and so generous a support to science as is exemplified in the Bureau of Standards. To-day its appropriations approximate two and a quarter million dollars a year, a larger income than most of our universities." Referring to the Bureau and the maintenance of a high standard of living, he said, "It is only through the support of agencies of this character, and hundreds of other institutions engaged in scientific research, that we may expect with confidence that as our population grows we can still add this increment of comfort and luxury which we have enjoyed in the last century." Addresses were also given by Dr. F. A. Wolf, who referred to the time when the quarters of the Bureau consisted of two basements in the Coast Survey building on Capitol Hill; by Dr. Stratton, a former Director of the Bureau, and by Mr. Cortelyou, a former Secretary of Commerce, who spoke of the hundreds of men of high scholarship found in the Bureau, and recalled a story of Edison who, being asked by an interviewer to name the four most useful men he knew, replied, "Oh, you wouldn't recognise them. They're working around in laboratories."

The expedition to New Guinea of the Smithsonian Institution and the Scientific Research Society of the Dutch East Indies, which has penetrated 250 miles into the interior of Dutch New Guinea under the leadership of Prof. Stirling, has reached Singapore on its way back to the United States. According to a dispatch from the Singapore correspondent of the *Times* in the issue of Jan. 14, 8000 ethnographical specimens, a large botanical collection, and much information concerning the pygmy races has been obtained. It will be remembered that in the reports on the progress of this expedition which have been issued by the Smithsonian Institution from time to time, special stress has been laid on the value of the work in mapping and exploration which has been made possible by the use of the aeroplane. The mountain barrier was crossed and the entire upper reaches of the Bouffaer River, hitherto unknown, were mapped. The original intention of visiting Lake Habbema, at an estimated altitude of 12,000 ft., by flying was abandoned; but the expedition reached a height of 9000 ft. where three months were spent among the pygmies. These proved to be most hospitable and friendly, in contrast to the Papuans of the coastal area, who attacked the camps, the canoes, and the transport, when several of the natives were killed The expedition would appear to have been more fortunate than travellers in other parts of New Guinea in their relations with the pygmies, as it has usually been found difficult to establish contact with them.

An appeal for contributions to a Maya Exploration Fund has been issued by Sir Frederic Kenyon, Director of the British Museum. As a result of the excavations carried out last year on the site at Lubaantun, an invitation has been tendered to the trustees of the British Museum by the Government of British Honduras to undertake the supervision of the archæological exploration of the Colony. The trustees are prepared to accept the responsibility if funds allow; but as the resources at their disposal are limited, they ask for the financial support of the British public in this undertaking, which promises results of exceptional importance. A capital sum of £40,000 to £50,000 is required to meet an annual cost of £2000 for exploration from year to year. British Honduras, though a small territory, contains remains of every phase of Maya civilisation. As explorations of the last two or three years have shown, it is impossible to place any limit to the extent and character of the material which may be forthcoming from this area to help in elucidating the fascinating problems which bear upon the origin and development of the prehistoric culture of Central America. At Lubaantun itself, in the course of two seasons' work, features unique in Maya art and architecture have been brought to light. That the continuous and systematic archæological exploration of the country should be undertaken at the request of the Colonial Government is in itself a gratifying mark of the recognition of the importance of these priceless monuments of antiquity, which hitherto have not only been utterly neglected by the authorities, but have not even been protected from the vandalism of any chance comer.

A booklet entitled "The National Institute for Research in Dairying: Its Work and Needs," compiled by the staff, deals with the inception, development, and aims of the National Institute for Research in Dairying, which is now located (under the University of Reading) at Shinfield, near Reading. During the time that the Institute has been established—some fourteen years—it has overcome many of its initial difficulties and has tackled some of the pressing problems of dairying with vision and enthusiasm. In face of what has been accomplished, it is to be hoped that the question of finance, which still hinders the work, will receive attention. It is not only those directly connected with dairying who are indebted to the Institute, but also the general public for the benefits which arise from the Institute's campaign for clean milk. The work of the Institute is classed under the headings of (*a*) management and feeding of dairy stock, (*b*) the chemical constitution and other properties of milk and milk products, (*c*) the methods of handling and distribution of milk. In each of these sections, not only has attention been given to the practical aspect of the various questions, but also the underlying scientific problems have been thoroughly studied. This has necessitated a very large amount of chemical, physical, and bacteriological investigation.

From the beginning, the National Institute for Research in Dairying has placed the production of clean milk in the forefront of its programme, and it has succeeded in stimulating a very keen interest in this subject throughout England. At the present time there is a steady increase in the number of clean-milk competitions, which are mainly organised by the county authorities. In 1925 the number of these competitions totalled 35, and there is every reason to expect an increase in the future. Demonstrations of methods to be employed in producing clean milk on the farm are now a feature of many county and local agricultural shows, and the visits of the county dairy instructors or instructresses to the farms in their respective areas are spreading the knowledge which is so vital to success. Most of these dairy teachers have been to a special course of instruction at the National

Institute, so that, in addition to research, the Institute plays a very important part in training and stimulating those who are able to influence the farmer in this important question of clean, safe milk.

THE inaugural meeting of the Institution of Fuel Technology was held in London on Dec. 7 and 8 last. Sir Alfred Mond, in his presidential address, discussed the problem of fuel generally in an interesting and stimulating manner. He pleaded for more co-operative effort in the scientific development of fuel, and more optimism in industry as a whole. T. Hardie read a paper on modern practice in gas manufacture, based on the experience of the Gas Light and Coke Co. The thermal efficiency of carbonisation in modern vertical retorts has reached 85 per cent., and of carburetted water-gas manufacture nearly 70 per cent. Prof. R. T. Haslam, Massachusetts Institute of Technology, contributed a theoretical discussion on the combustion of carbon, and Sir Richard Redmayne a paper on the German brown coal industry, giving a very comprehensive account of the fuel itself and of the various processes to which it is now put; it emphasised the potential value of such a low-grade fuel when suitably exploited. A paper was contributed by W. E. Groume-Grjimaflo, of Petrograd, on his theory, based on hydraulic analogy, of the flow of furnace and heating gases, and its application to furnace construction. S. McEwen discussed the economies of low-temperature carbonisation, with special reference to the supply of pulverised fuel and its use. Dr. J. S. Owens gave an account of modern views on smoke and public health. The *Fuel Economist* for December contains a full account of the papers and discussions, which are of considerable interest and value.

WE learn from the report for the past year of the British Photographic Research Association, which was presented to the Council by the Director of Research on Nov. 23, that the Association has now entered on the last year of its second period of grant from the Department of Scientific and Industrial Research, and is therefore obliged to consider the question of the future. The Association is supported financially by the subscriptions of its members, supplemented by a grant from the Department, and in this manner has been enabled to make a really good start and thoroughly to justify its existence during the last nine years. We wish we could add that it was thoroughly well established, but the obviously uncertain nature of its income must be a source of anxiety to every member of the staff, and now and then leads to the loss of valued assistants, who naturally are ready to pass to appointments of a more apparently secure character.

AT the last annual general meeting of the Association, a resolution was passed that "it is of great importance to the industry that the British Photographic Research Association should be continued, and that every effort should be made to secure its continuation on a sound financial basis." We sincerely hope that these efforts will be made, and that they will be crowned with a success that will enable the Association not only to feel that it is well established but also that it may look forward to a healthy growth. The last year has added eight to the total of its scientific communications published, and two others are in the press. In addition, four summaries of literature have been circulated, frequent meetings of the staff with members of the scientific staffs of manufacturing firms have been held, and three lectures have been given in response to "requests from outside circles." Assistance or advice given confidentially to the members of the Association is one of the other activities of the research staff, but its main work is to supplement and not to replace the research departments of the various manufacturing firms, by attacking fundamental problems rather than those immediately concerned with factory work. It is pleasing to note that a certain feeling of distrust that existed at first on the part of some manufacturers has now been replaced by one of confidence in the research staff of the Association and its Director.

THE Society for Experimental Biology met at Bedford College, London, on Jan. 10 and 11. At the first session Prof. A. E. Boycott described experiments to determine the cause of the local distribution of Planorbis and Bithinia in a group of ponds, Mr. R. E. Chapman showed the effect of bicarbonates on photosynthesis in water plants, Dr. W. K. Slater discussed the effect of anaerobic conditions on the metabolism of the cockroach, and Dr J. Needham communicated a paper on the carbohydrate metabolism of the developing egg. A number of demonstrations of plant and animal experiments were also made. The second session, which was devoted to a symposium on the relative growth of parts, in which Prof. J. S. Huxley, Miss M. Shaw, and Messrs. M. Perkins, John Hammond, J. T. Cunningham, and others took part, was characterised by lively discussion. In the third session Dr. C. M. Yonge described intracellular digestion in Metazoa and Mr. G. F. Marrian explained the inter-relationships of respiratory pigments. Mr. G. P. Wells summarised experiments on the action of cations on invertebrate muscle, and Mr. V. J. Clancy described recent work on the biochemistry of scleroproteins which go to form skeletal and protective structures in animals and plants. At the annual meeting twenty-two new members were elected, and on the evening of Jan. 10 a dinner at the Florence Restaurant was attended by about fifty members and guests.

AT the fourth annual meeting of British zoologists in the rooms of the Zoological Society on Jan. 8, it was proposed by Prof. Stanley Gardiner, and carried unanimously, "That this meeting represents to the Trustees of the British Museum the desirability of equipping zoological expeditions for the purpose of obtaining as full a record as possible of the past and present fauna."

THE Research Association of British Paint, Colour and Varnish Manufacturers has made arrangements to purchase a property at Teddington near to the National Physical Laboratory, to be used as its research station and laboratories. It is hoped that the premises will be ready for occupation by the end of March. A Technical Advisory Committee has been appointed to consider and draw up the preliminary programme of research, and a second member of the technical staff has been appointed, namely, Dr. J. O. Cutter.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant master to teach engineering science in the day junior Technical and Evening Technical Schools, Truro—The Principal, Technical Schools, Truro (Jan. 28). A secretary to the Royal Asiatic Society—The Secretary, Royal Asiatic Society, 74 Grosvenor Street, W.1 (Jan. 29). A lecturer in machine drawing and design in the department of engineering, University College, Nottingham—The Registrar (Jan. 31). An assistant editor of British Chemical Abstracts—B (Applied Chemistry)—The Secretary, Bureau of Chemical Abstracts, 46 Finsbury Square, E.C.2 (Feb. 4). A principal of the Teachers' Training College and professor of education in the University of Western Australia—The Agent-General for Western Australia, Savoy House, Strand, W.C.2 (Feb. 10). A test assistant at the Royal Aircraft Establishment for general assistance to the scientific staff of the wind tunnel section of the Aerodynamic Department—The Chief Superintendent, R.A.E., South Farnborough, Hants. (Reference No. A. 142).

Our Astronomical Column.

COMETS.—Mr. Blathwayt, who discovered his first comet a year ago, has now found a second one, which is of the ninth magnitude, being the brightest comet that has been in sight for several months. The place of discovery is Braamfontein, near Johannesburg, and the position on Jan. 13 at $1^h\ 28{\cdot}0^m$ is given as R.A. $15^h\ 44^m\ 0^s$, S. Decl. 29° 46′, daily motion $+12^s$, S. 50′. The comet is too far south for observation in England, but may come northward later.

Prof. J. Comas Sola, of Fabra Observatory, Barcelona, has discovered an object of doubtful character (comet or minor planet). Its place on Jan. 10 at $0^h\ 30{\cdot}0^m$ U.T. was $8^h\ 19^m\ 20^s$, N. Decl. 2° 22′, daily motion $-1^m\ 28^s$, S. 18′, magnitude 12·4. If it is a minor planet, it must have a fairly small mean distance and a high inclination, so that it is an object of interest in any case.

Dr. A. C. D. Crommelin has deduced the following orbit of comet 1926 f. (Comas Sola) from photographic observations by G. Merton and F. J. Hargreaves on Nov. 10, Dec. 3, Dec. 24:

$$\begin{aligned} T &= 1927 \text{ Mar. } 22{\cdot}1992 \text{ U.T.} \\ &\left.\begin{aligned} \omega &= 38^\circ\ 27'\ 30''{\cdot}8 \\ \Omega &= 65\ \ 36\ \ 29{\cdot}2 \\ i &= 13\ \ 45\ \ 40{\cdot}0 \end{aligned}\right\} 1926{\cdot}0 \\ \phi &= 35\ \ \ 5\ \ 39{\cdot}5 \\ \log q &= 0{\cdot}248639 \\ \text{Period} &= 8{\cdot}51645 \text{ years.} \end{aligned}$$

These elements indicate a close approach to Jupiter in May 1912, and are therefore compatible with the suggestion of identity with Spitaler's comet 1890 VII. Very large perturbations are required to make this possible; the aphelion distance having increased from 5·08 to 6 568, which latter is 1¼ units beyond the orbit of Jupiter.

EPHEMERIS FOR 0^h.

	R.A.	N. Decl.	log Δ.
Jan. 24	$2^h\ 39^m\ 46^s$	18° 40′	0·148
Feb. 1	2 49 52	20 26	0·166
„ 9.	3 2 10	22 14	0·183

The comet should be readily observable until May, which would be six months after discovery. It remains within a few degrees of Mars for some time.

THE MINOR PLANETS.—Prof. H. N. Russell gives in the *Scientific American* for January an interesting summary of our present knowledge on this subject. Keen visual scrutiny revealed 300 planets between 1847 and 1891; then the photographic method was introduced and led to a great increase in the rate of discovery, more than 1800 discoveries having been announced between 1891 and 1926. At present, 1046 planets have been well observed and have received permanent numbers; about 1000 more are known to exist, but their orbits are only roughly determined.

The search cannot be pronounced a waste of time, if only for the fact that it led to the discovery of Eros, which gives such an excellent means of determining the solar parallax. Albert, Alinda, and Ganymede resemble Eros in travelling partly within the orbit of Mars. The group of six Trojan planets, which make equilateral triangles with Jupiter and the sun, give an example in the heavens of a solution of the 3-body problem which Laplace had announced from theory more than a century earlier. Dr. Baade's remarkable asteroid Hidalgo, the orbit of which extends from Mars to Saturn and is more eccentric than many cometary orbits, also presents interesting features, and raises some puzzling questions in cosmogony.

It is satisfactory that international co-operation in observing the minor planets, which broke down during the War, is being established afresh. Prof. M. Wolf's first photographically discovered planet was lost for some thirty years, and was then recovered in America, though it needed a long series of observations to establish the identity.

SATELLITES OF MARS.—These satellites offer some interesting problems, owing to their close proximity to Mars, with resulting shift to their orbit planes, due to the planet's oblateness. There is also the possibility of some alteration of the mean motion of Phobos as a reaction of tidal friction. Hence the series of measures made in 1924 with the 26-in. equatorial at the United States Naval Observatory, Washington, by A. Hall, E. C. Bower, and Miss E. A. Lamson (*Astr. Jour.*, No. 873) is of interest. The corrections to the mean daily motions are:

	Deimos.	Phobos.
Hall . .	−0·000060°	+0·000099°
Bower . .	−0 000107°	+0·000097°

The deduced values of the reciprocal of the mass of Mars are:

	Deimos.	Phobos.
Hall . .	3,108,500	3,157,100
Bower . .	3,127,200	3,212,100

Giving Deimos double weight, owing to the larger arc subtended by its orbit, the weighted mean is 3,140,100. Thus the observed value of the mass is nearly 2 per cent. smaller than the accepted value, rather a large difference.

Research Items.

Anthropometry of the Aborigines of South Australia.—Dr. T. D. Campbell and Dr. Aubrey J. Lewis have published in the *Transactions of the Royal Society of South Australia* for 1926 observations on 28 aborigines (11 males and 17 females) from the camp at Ooldea on the edge of the Nullarbor Plain. Most of them belong to the Alinjera group, a few to the Willoorara group. Individual measurements are given, the mean values working out as follows: Stature, 1593·4; cranial length, 187; cranial breadth, 135; nose height, 43·2; nose breadth, 44·8. The means of the indices are: Cephalic, 72·2; facial, 81·7; nasal, 104·6; ear, 53·1; radio-humeral, 81·5. The figures are compared throughout with those collected by Prof. Wood-Jones and Dr. Campbell on varying numbers of individuals, in one case—stature—more than three hundred, and are found to approximate to them fairly closely. They go to confirm the assertion that the aborigine of Central Australia belongs to a pure stock with well-defined and constant physical characters. He is dolichocephalic, platyrhinic, and dolichokerkid, the breadth of his ear is about half its length, while as to his jaw, the mean index is fairly constant though there is considerable individual variation.

Early Records of Californian Indians.—Although Bancroft, for the purpose of his "History of California," drew freely on most of the available sources, a re-examination of these, mostly diaries of Spanish priests who accompanied punitive or exploratory expeditions—records not generally available—has shown that they contain much supplementary material of archæological or ethnological value. Mr. E. W. Gifford and Mr. W. E. Schenk, who have already published material relating to the southern San Joaquin Valley in the *University of California Publications in American Archæology and Ethnology*, have now issued the data relating to the California Delta region in vol. 23, No. 2 of the same series. The records of the expeditions in question extend from the year 1772 to 1849. They throw an interesting light on the sources of food supply, comment being made on several occasions on the vast quantity of game. At Carquinez great mounds of fresh-water mussel shells were observed in the vicinity of a native village; but probably two different stages of culture were represented. Of the general conclusions which can be drawn, the most interesting is that based on evidence pointing to the infiltration of European influence. In 1819 the capture of forty-nine horses belonging to the Muquelemes near the Calaveras-San Joaquin confluence is significant, and the object of many of these expeditions was to recover escaped converts. The possible mixtures and modifications of physical types which resulted imposes great caution in the interpretation of skeletal evidence from certain groups or regions. Radical differences in cultures are difficult to note. Conclusions as to the numbers of the population require a large margin of error. In 1806 there may have been anything from 3,000 to 15,000 inhabitants. In 1870 the Indian population in this area had fallen to 5.

The Mandshurian Tiger.—The area inhabited by the tiger in the Far East is widely separated from the main area comprising India and southern China. The Mandshurian tiger, according to recent researches by Baikov, recorded in *Priroda*, Nos. 5-6, 1926, should be regarded as a species distinct from the southern tiger and more closely related to the fossil cave tiger of Europe. It differs even in its habits from the southern species, which lives in the jungle, for the Mandshurian tiger lives in *taiga*, *i.e.* in the dense forests peculiar to eastern Siberia, and it definitely dislikes heat, going up to the mountains in summer, while in winter it is perfectly comfortable even during the hardest frosts. The principal prey of the Mandshurian tiger is wild pig, but it is doing a great deal of damage to cattle, while it also often attacks men even in the day-time.

Agricultural Map of Russia.—The Russian Institute of Applied Botany, in Leningrad, has just published a very interesting agricultural map of the country compiled by Prof. I. F. Makarov. The map itself is reproduced on a fairly large scale in colours, and shows, by the 'dot' method, the relative distribution and density of crops in the country, a single dot representing 1000 hectares of crops. This method makes the map exceedingly instructive, as even a superficial glance is sufficient to show the very irregular and peculiar distribution of cultivated land in Russian territory. Very concentrated dots indicate the highly cultivated areas of the Ukraine, of the northern Caucasus, and of the Volga region, while smaller in size but nearly as dense accumulations of dots indicate the numerous oases in the vast deserts of central Asia, which are otherwise quite devoid of dots. Of particular interest to every naturalist is the northern limit of agriculture, which is also shown on the map. The line drawn on the map shows the northernmost limits of actual cultivation of cereals during the last century; it does not coincide, however, with the northern limit of possible agriculture, or with the limit of a stable agriculture forming an economic basis of the population; it lies between these two lines. The course of the line on the map begins in European Russia at lat. 62° and runs eastwards more or less parallel to the White and the Polar Seas, but near the Ural Mountains it suddenly drops to lat. 60°. Having crossed the Urals the line runs across Siberia, now ascending, now descending again. An interesting point is shown in eastern Siberia, where the line forms an enormous loop embracing the lowlands of Yakutsk with the river Lena and its tributaries. The northernmost point in Siberia touched by the line is lat. 65° N., this being in the Yakutsk province; but in the Amur region, between the same meridian, the line comes down only to lat. 48° N., and reaches the Japanese Sea at lat. 45° N. Isolated outposts of agriculture occur in Siberia far beyond the line, and even well beyond the Arctic circle. Apart from the general map, this publication contains a number of regional maps, showing the distribution of crops in various parts of Russia in detail, as well as explanatory text giving much statistical information.

An Apparatus for Catching the Micro-fauna of the Sea-bottom.—A new apparatus for this purpose is described by Dr. Th. Mortensen (*Saertryk af Vidensk. Medd. fra Dansk naturh. Foren.* Bd. 80, pp. 445-451). Recent investigations have indicated both the magnitude and importance of the micro-fauna of the bottom deposits in the sea, but it has always been difficult to obtain adequate samples of this, since it is very laborious to sift out microscopic animals from the mass of material brought up in the dredge or trawl, while the Petersen grab, though more satisfactory, gives but a small sample. Dr. Mortensen's apparatus, designed to remedy this, consists of a fine silk net attached to a rectangular iron frame the whole being prevented from sinking into the bottom deposits by a pair of thin zinc plates which are attached to the iron frame in front and to one another behind and at either side. They are bent upwards at the anterior end like the runner of a sledge and are almost as long as the net which lies between them. In use the net skims along the surface of the mud and collects an abundant sample of the micro-fauna from the surface layers. When used on a sandy bottom, an iron bar is attached a little distance in front of the mouth of the net so as to stir up the light organisms, which remain floating long enough to be caught in the pursuing net. Excellent results have been obtained in depths up to 94 metres with this net, abundant catches of nematodes, planarians, small annelids, ostracods, copepods, and many small molluscs having been secured.

Chromosome Measurements. — The accurate measurement of chromosomes is a difficult field in which little has yet been done. An extensive and laborious series of such comparative measurements has recently been made by Nesta Ferguson (*Phil. Trans. Roy. Soc.*, vol. 215 B, pp. 225-253) on the Aloinæ, a group of Liliaceous genera comprising Aloe, Gasteria, Apicra, and Haworthia. More than fifty species were compared as regards the chromosome content of their nuclei. In all these genera there are four long chromosomes and three short ones, but seven species and varieties were found to be tetraploid, having eight long and six short chromosomes. Tables of measurements and graphs of variation in chromosome length are followed by measurements of width in different stages of mitosis, and, finally, the average volume of the chromatin in the corresponding nuclei from nine different species is computed. In the genus Haworthia this volume is 40·4 μ^3 in *H. Cooperi*, 107·7 μ^3 in *H. radula*, and 208·6 μ^3 in the tetraploid *H. tessolata parva*. It is concluded that the last has arisen through a duplication of the complete chromosome set of the nucleus. Differences in the mean length of the long chromosomes from species to species are also found, which may be significant.

The Japanese Earthquake of Sept. 1, 1923.— Broadly speaking, the origin of this great earthquake covers the whole of the land and sea-basin, which have undergone conspicuous topographical changes (Nature, vol. 115, 1925, pp. 65-66), and especially the seismic focal zone that crosses the central part of Sagami Bay from north-west to south-east. From an analysis of the seismograms obtained at Tokyo and other stations (*Proc. Imp. Acad. Tokyo*, vol. 2, 1926, pp. 401-404), Prof. A. Imamura suggests that the great earthquake consisted of a group of earthquakes which originated successively at brief intervals in different parts of the focal zone. He distinguishes in particular three earthquakes, though there may have been others in the south-eastern portion of the zone—the first, not a violent earthquake, with its epicentre below the sea and about midway between Misaki and Manazura; the second, three seconds later, a very great earthquake, with its epicentre on land about 30 miles north-north-west of the other; and the third, a very sharp earthquake, about 4¼ seconds later still, with its epicentre near the coast and due north of the first epicentre.

Miocene Mollusca from Florida. — Julia Gardiner has studied and discusses "The Molluscan Fauna of the Alum Bluff group of Florida" (U.S. Geol. Survey: *Professional Paper* 142, A-D). The Alum Bluff deposits comprise three distinct faunas, which characterise three formations known in descending order as the Shoal River, the Oak Grove Sand, and the chipola. The whole series is overlain by the Choctawhatchee Marl, and is referable to the Miocene age. The author briefly sketches the history of the Alum Bluff group and gives a map of the places of its occurrence, with tables of the distribution of the fauna and local distribution of the species. The systematic descriptions (occupying some 147 pages) follow, arranged according to Dr. Dall's classification, and include many new species, while the 27 plates of fossils are a delight to look at. Each of the four parts into which, for some occult reason, the paper is divided, is furnished with an index. One index to the whole would have been much more useful and satisfactory.

Oil Surveys in Northern Alaska.—A recent bulletin of the United States Geological Survey (No. 783-E) by Messrs. P. S. Smith, J. B. Mertie, and W. T. Foran, is in the nature of a progress report of the extensive surveys being undertaken in this territory, more particularly the Naval Reserve of 35,000 square miles set aside by President Harding in 1923; the main object of this work is the location of possible oil deposits and, if successful, their development under Government administration. Oil has been definitely proved in the Reserve in the vicinity of Cape Simpson, where two distinct seepages occur, but under what conditions it originated and in what quantity it is available, are points as yet undetermined. The general interest of the report is that part of it which touches on the special problems of development which must necessarily arise when exploiting an oil-field near to or within the Arctic Circle. For example, climatic conditions make it impossible for ships to gain access to the Reserve by sea except in the period between August 1 and early September; "even during this short period they run the hazard of being caught in the ice and lost." Clearly any quantity of petroleum won from this region could not be moved by ocean-going vessels, especially as there is no harbour as yet suitable to ships of the tanker class. Alternatively, pipe-line transport from the Reserve to an ice-free harbour would probably have to be more than 1000 miles long. "Through half this distance even trails, on which all supplies and materials would have to be hauled, are lacking, and for a third of the distance there is not even timber enough to build shelters for the workmen." Similar circumstances apply to railway construction, the cost of which would be prodigious. A further serious factor in the present case is that if the oil in transit is to be used for purposes of national defence, the line of supply would have to be safeguarded; in fact, the whole region would demand protection in view of its remoteness from Government centres. Thus a very large oilfield and a commensurate production would be necessary before the cost of practical solutions to these problems could be economically justified. Save for the strategic factor, much the same reasoning applies to the development of oilfields in north-west Canada, concerning which we hear much from time to time.

Antarctic Meteorology.—The *Boletin Mensual* of the Argentine Meteorological Office, of which the issue for 1923 has now been published, contains a résumé of the observations taken at 8, 14 and 20 hours at 74 meteorological stations in the Republic, including two stations outside the Republic at South Georgia and the South Orkneys. These observatories are the only permanent ones existing in antarctic and subantarctic regions, and so have particular value. In spite of their low latitude, 60° 44′ south, the South Orkneys had only three months with a mean temperature above freezing point, and the highest mean, in February, was only 1·2° C. In midwinter the mean fell to more than 10° below freezing point. In South

Georgia conditions were more temperate, eight months having means above freezing point, and in the warmest month the mean rose to 6·1° C. Precipitation at the South Orkneys showed the low level for the year of 481 mm.; at South Georgia it was 1257 mm. These figures, which represent fairly well the average conditions, are of interest in relation to the heavy glaciation of both island groups.

Viscosity of Metals.—Parts 1 and 2 of vol. 134 of the mathematical and physical division of the *Sitzungsberichte* of the Academy of Sciences of Vienna contains a paper by Dr. F. Hettwer, of the Physics Institute of the University, on the viscosity of metals. The specimens were cylinders 0·8 cm. diameter, 10-14 cm. long, with their axes vertical. The upper end was clamped in a fixed support, the lower in a support to which a given torsional couple about a vertical axis could be applied by means of weights. The temperature was kept constant by water circulation. The twist of the cylinder produced was measured by means of a circular scale, and its small changes by means of a mirror and scale. When first the torsional couple is applied, elastic fatigue affects the twist for some time, and the observations taken during the daytime for 10-14 days afterwards are used. The values of the viscosity obtained are: for lead 4·7, tin 24, aluminium 75, and zinc 330 multiplied by 10^{14}. For alloys the laws of viscous flow appear to be more complicated than in the case of pure metals, and the viscosity higher.

The Electrical Conductivity of the Atmosphere.—The issue of the *Physikalische Zeitschrift* for Dec. 1 contains an account of the observations made on this subject during the past three years by Dr. Rose Stoppel, with the assistance of the Notgemeinschaft der deutschen Wissenschaft. The conductivity was determined by the leak from an insulated wire 150 cm. long, 0·2 cm. in diameter, which was charged every half-hour by contact for an instant with one pole of a battery of 200 volts, the other pole of which was earthed. The decrease of potential of the wire was recorded every two minutes by a Benndorf electrometer. The observations were made in a cellar in Hamburg and in a dark room in Akreyri in the north of Iceland. At each place of observation the conductivity has a daily period with a maximum between 4 and 6 in the morning local time, uninfluenced by the period of midnight sun, but much reduced at times of aurora. The variations of conductivity are not to be accounted for by changes of sunlight, of temperature, pressure, or degree of saturation of the air, and are probably due to cosmical radiation undetected up to the present time.

Methods of Testing Electric Lamps.—The very large number of incandescent electric lamps which have to be tested to stringent specifications each year by the Bureau of Standards for the American Government departments have made it necessary to invent new methods and auxiliary apparatus so as to speed up the tests and reduce the cost. An initial photometric test of the lamp in lumens per watt is first made. Fortunately the changes in life output and efficiency for changes in voltage are sufficiently consistent for lamps of a given type to permit of computation of the required voltage at which the lamp is to be run for a life test. This voltage is considerably higher than the manufacturer's nominal service rating, and hence, as the life is much shorter, a great saving in time and money is effected. All lamps are rated and tested on the basis of total light output in lumens and efficiency in lumens per watt. As the factors for deducing the mean spherical candle-power of vacuum tungsten lamps from the mean horizontal candle power are known, they are actually measured on a horizontal photometer bar. Other lamps are measured on an integrating sphere 30 inches in diameter, the test lamp occupying a fixed position within the sphere. Very large lamps are measured in an 88-inch sphere. These three photometers have special auxiliary devices by which the necessary computations are made in a semi-automatic manner at the time the observations are taken. Detailed descriptions of these devices are given in a paper, "Recent Developments in Lamp Life-Testing Equipment and Methods," published by the U.S. Bureau of Standards (No. 325). One great advantage of the methods described is that the scales employed may be easily and quickly read without eye-strain.

Magnetisation in Alloys.—The Bell Telephone System in the United States maintains a very large research organisation called the Bell Telephone Laboratories Inc. In these laboratories G. W. Elmen discovered permalloy, an iron-nickel alloy with a permeability enormously greater than that of iron in low magnetic fields. This alloy is of the greatest importance in submarine telegraphy. In the *Bell Laboratories Record* for December, L. W. McKeehan writes an interesting popular paper giving what he calls a physical background to the properties of permalloy. In the new alloy, X-ray analysis shows that there is apparently nothing peculiar about the crystals. It exhibits a uniform solid solution of iron and nickel. A great deal of study has been devoted recently to magnetic measurements of elastically deformed specimens. It appears that permalloy acts in an entirely natural manner. It is known that magnetisation of iron, nickel, and cobalt is accompanied by changes in the interatomic forces. This is shown by the minute changes in overall dimensions. If these changes take place suddenly, energy ought to be expended, and this the author identifies with magnetic hysteresis losses. Magnetic hysteresis losses are abnormally low in permalloy. When its components iron and nickel are separately magnetised, the iron expands and the nickel contracts in the direction of the magnetic axis. It is probable, therefore, that somewhere in the region of iron and nickel alloys there will be neither expansion nor contraction on magnetisation. Two Japanese experimenters have reported that the critical composition where this phenomenon occurs makes the magnetic behaviour of permalloy most strikingly abnormal. The atoms of the iron and the nickel act together in groups and there are no sudden changes in their position. Hence hysteresis loss does not take place. This theory ought to be helpful in discovering other magnetic alloys of great theoretical interest and commercial importance.

Artificial Silk.—The *Journal of the Royal Society of Arts* for Dec. 10, 1926, contains a paper on artificial silk, read before the Society on Nov. 17, by T. Brough, chief designer of Messrs. Courtalds, Ltd. Artificial silk possesses certain features which make it distinct from the natural substance, and for this reason its name is rather misleading, but the resemblance between the two fibres is seen from the description of the processes by which they are produced. Of the four processes now in use for the production of artificial silk, the viscose is the most important, about seventy-six per cent. of the world's supply being manufactured by this method. By judicious use of artificial silk, either alone, or with the assistance of other fibres such as cotton, worsted, or natural silk, a large variety of beautiful textures can be woven, and illustrations of examples of these fabrics are reproduced.

Paris Academy of Sciences.

PRIZES AND GRANTS AWARDED IN 1926.

MATHEMATICS.—The Bordin Prize has been awarded to Serge Bernstein for his "Leçons sur les propriétés extrémales et la meilleure approximation des fonctions analytiques d'une variable réelle"; the Poncelet Prize to Paul Montel for his mathematical work as a whole; the Francœur Prize to Gaston Julia for his works on the theory of functions.

Mechanics.—The Montyon Prize has been awarded to Kyrille Popoff for his book, "Les méthodes d'intégration de Poincaré et le probleme général de la balistique extérieure"; the Henri de Parville Prize to Antoine Alayrac for his work on the theory of flight; the Henri Bazin Foundation to Léo Escande and Marcel Ricaud for their researches concerning the mechanics of fluids.

Astronomy.—The Lalande Prize has been awarded to Armand Lambert for his catalogue of fundamental stars; the Damoiseau Prize to Joseph Renaux for the whole of his work; the Valz Prize to Frank Schlesinger, Director of the Yale University Observatory, for the whole of his work, particularly for his researches relating to the measurement of the parallax of stars by the trigonometric method; the Janssen Prize to Francisco Miranda da Costa Lobo for the whole of his astronomical work; the La Caille Prize to Gaston Fayet for the whole of his astronomical work.

Geography.—The Delalande-Guérineau Prize has been awarded to Jacques Hippolyte Grossard for his geodesic work in the Nile and Congo basins; the Gay Prize to Henri Michel for his studies on the improvement of tidal rivers; the Tchihatchef Prize to the late Jean Govin for his geodesic work; the Binoux Prize between François Roland for his work, "Les cartes anciennes de la Franche-Comté," and Jules Gaultier for his researches on surveying instruments.

Navigation.—The Prize of 6000 francs (in equal parts) has been divided between Émile Georges Barrillon, for his study on the waves produced by the motion of a ship, and André Apard for his work on the hygroscopic properties of the B powders; the Plumey Prize (2000 francs) has been awarded to Frédéric Marquet for his treatise on navigation.

Physics.—The La Caze Prize has been awarded to Charles Fabry for the whole of his scientific work; the Hebert Prize to Paul Bunet for his electrotechnical work; the Hughes Prize to François Croze for his work in spectroscopy; the Clément Felix Foundation to Georges Reboul for the continuation of his studies on badly conducting substances.

Chemistry.—Montyon Prize (Unhealthy Trades). A prize (2500 francs) has been awarded to Ernest Portier for his work as a whole on industrial hygiene, and an honourable mention (1500 francs) to Louis Chelle for his researches on gases used in warfare; the Jecker Prize is divided between André Wahl (6000 francs) for his work in organic chemistry and Gustave Vavon (4000 francs) for his researches on catalysis with platinum black; the La Caze Prize to André Job for his researches on the mechanism of oxidation; the Cahours Foundation between Raymond Delaby for his work on the homologues of glycerol, and Michel Samson for his work on glass; the Houzeau Prize to Louis Hackspill for his work in inorganic chemistry.

Mineralogy and Geology.—The Fontannes Prize has been awarded to Léon Moret for his "Contribution à l'étude des spongiaires siliceux du Crétacé supérieur français."

Meteorology and Physics of the Globe.—The Victor Raulin Prize has been awarded to Joseph Lacoste for his work in mineralogy and atmospherics.

Botany.—The Desmazières Prize has been awarded to Robert Kühner for his memoir entitled "Contribution à l'étude des Hyménomycètes et spécialement des Agaricacées"; the Montagne Prize divided between Georges Mangenot (1000 francs) for his memoirs on algæ, and Pierre Dombray (500 francs) for his work entitled "Contribution à l'étude des corps oléiformes des hépatiques des environs de Nancy"; the De Coincey Prize to Irénée Thériot for work on the analysis and specification of exotic mosses.

Anatomy and Zoology.—The Cuvier Prize has been awarded to Édouard Chatton for his work on the Protozoa; the Savigny Prize to Édouard Lamy for his work on molluscs; the Thore Prize to Rémy Perrier for his two volumes on entomology in his "Faune de la France."

Medicine and Surgery.—Montyon Prizes have been awarded to Maurice Blanchard and Gustave Lefrou (2500 francs) for their researches on the acute spirochætoses of French equatorial Africa, to Louis Fournier and Louis Guénot (2500 francs) for their work on the bismuthotherapy of syphilis, and to Étienne Burnet (2500 francs) for work on Mediterranean fever. Honourable mentions (1500 francs) to Jules Le Calvé for his work entitled "L'œdème, étude expérimentale et clinique," to W. B. Palgen for his essay on the biology of some bacteria, and to Alfred Weiss for his clinical and experimental researches on colectomy. Citations to Maurice Cuvigny, Leroux-Robert, Raymond Turpin, Marcel Sendrail, and Charles Dejean; the Barbier Prize to Jules Bridré and André Donatien for their work on the micro-organism of contagious agalaxy of the sheep and goat; the Bréant Prize between Yves Kermorgant (3500 francs) for his work, "Contribution à l'étude de l'étiologie des oreillons," and Charles Pérard (1500 francs) for his work on coccidioses of the rabbit; the Godard Prize to Christian Champy for his work, "Sexuality and Hormones"; an honourable mention to Jacques Benoit for his work, "Recherches anatomiques, cytologiques et histophysiologiques sur les voies excrétrices du testicule chez les mammifères"; the Mége Prize to Alberico Benedicenti for his work, "Malati, medici e farmacisti"; the Bellion Prize to Stefan Nicolau for the whole of his work; the Larrey Prize to Charles Spire and Pierre Lombardy for their work, "Précis d'organisation et de fonctionnement du service du santé pendant la guerre."

Physiology.—The Montyon Prize has been divided between Marcel Duval, for his physico-chemical and physiological researches on the internal medium of aquatic animals and the modifications produced under the influence of the external medium, and Auguste Quidor and Marcel Hérubel for their memoir on a new theory of visual perception and its applications; the La Caze Prize has been awarded to Georges Weiss for his work in biological physics; the Pourat Prize has been divided between Stefan Mutermilch (1000 francs) for his work on normal and artificial hæmolysins, and Albert Berthelot (1000 francs) for his work in bacteriology and medicine; the Martin-Damourette Prize between Henry Chabanier for his work on the rôle of the kidney in diabetes, and Maurice Chiray and Yon Pavel for their work on the contractility of the biliary vesicle; the Philipeaux Prize has been awarded to Henri Simonnet for his work on the liposoluble factor, with honourable mention to Émile Wagner for his memoir, "Le système nerveux de l'adrénalinosécrétion"; the Fanny Emden Prize to Louis Delherm and Albert Laquerrière for their work on the biological effects of various radiations.

Statistics.—The Montyon Prize has been awarded to the Institut de Statistique de l'Université de Paris for its contribution to the progress of applications of mathematics to statistics, finance, and political economy. Honourable mentions of 500 francs to Ernest Blin for his researches on the physical development of assisted children, and to Albert Ranc for his book, "Le budget du personnel des recherches scientifiques en France."

History and Philosophy of Science.—The Binoux Prize has been awarded to Henry de Varigny for his book, "La mort et la biologie."

Works of Science.—The Henri de Parville Prize has been awarded to René Legendre for his memoir on the concentration of hydrogen ions in sea water.

Medals.—The Berthelot medal has been awarded to Ernest Portier and to André Job.

General Prizes.—The Grand Prize of the mathematical sciences has been awarded to Eugène Bertrand de Fontviolant for his work on the resistance of materials; the Bordin Prize (physical sciences) to Auguste Pettit for his researches on serum for the treatment of infantile paralysis; the Lallemand Prize to Yvonne Sorrel-Dejerine for her work entitled "Contribution à l'étude des paraplégies pottiques," and a very honourable mention to Pierre Hillemand for his work, "Contribution à l'étude des syndromes de la région thalamique"; the Serres Prize to Charles Pérez for the whole of his work in embryology; the Vaillant Prize to Mme. Lucie Randoin for her researches on the physiology of nutrition, with special reference to vitamins; the Jean Reynaud Prize to Mme. Alfred Giard, in memory of the biological work of the late Alfred Giard; the De Joest Prize to Alain Quemper de Lanascol for his work on the geometry of compasses; the Houllevigue Prize to Jean Rey for his work on the physical properties of petrol vapours and their laws of flow; the Saintour Prize to Pierre Fauvel for the whole of his work on annelids; the Jules Mahyer Prize to Louis de Broglie for his studies on the quantum theory; the Lonchampt Prize to Charles Dhéré for his work on electrodialysis and the purification of proteids; the Wilde Prize (in equal parts) between Armand Renier for his studies of the Belgian coal measures, and Bruneau de Laborie for his African explorations; the Caméré Prize to René Feret for his researches on cement; the Jérome Ponti Prize to Maurice Fréchet for his work on the theory of functions; the Gustave Roux Prize to Pierre Chevey for his work in zoology; the Thorlet Prize to Adolphe Richard; the Albert I. of Monaco Prize to Jean Charcot to permit him to complete the equipment of his vessel the *Pourquoi pas?*

Special Foundations.—The Lannelongue Foundation has been divided between Mmes. Cusco and Rück.

Prizes at the Grandes Écoles.—The Laplace Prize has been awarded to Georges Parisot; the L. E. Rivot Prize to Georges Parisot, Jacques Hémar, Louis Armand, and Louis Dherse.

Foundations for Scientific Researches.—The Trémont Foundation has been awarded to Edmond Marcotte for his work on internal combustion motors; the Gegner Foundation to René Baire for the whole of his mathematical work; the Hirn Foundation to Joseph Thoret for his researches on air currents; the Becquerel Foundation to Georges Bruhat for his work in optics and physical chemistry; the Bouchard Foundation to Maxime Ménard for his work on X-rays and radiations used in therapeutics; the Le Chatelier Foundation to Jean Cournot and Albert Roux for their studies on alloys by means of the X-rays.

The Geographical Association.

THE Geographical Association held its annual meetings on Jan. 6-8 at the London School of Economics. The address of the president, Sir Charles Close, on "Population and Migration," gave a statistical investigation of world population with special reference to the development of the British Dominions. The tendency of population growth, indicated by graphs of census returns, gives some foundation for a forecast of the future. Within three-quarters of a century from 1875, England will probably pass from the period of highest birth-rate—36 per 1000—to a stationary condition in which birth-rate and death-rate will balance. Any migration policy must take this tendency into consideration, as well as the absorption rate in the Dominions, estimated at 5 per 1000. This at present would give about 100,000 per annum, excluding the quota to the United States. It is a corollary of this population movement that the dissemination of geographical knowledge of the regions of the world must occupy an increasingly important position in education.

Maps constitute one of the most important groups of geographical documents. Even the significance of the 'Bactrian Triangle' of Bukhāra, Merv, and Samarkand, discussed by Dr. Eileen Power in relation to trans-Asian caravan routes, cannot be fully realised apart from a cartographical representation of the three great east-west highways in their physico-geographical setting. But the mapping of such regions prior to the coming of the aeroplane has been financially almost impossible. Air surveys open a new era. Already such regions as the lower course and delta of the Irrawaddy, and the coastlands of British Guiana, have thus been mapped. Some 100,000 square miles of Canada have been surveyed from the air. Even vegetation distribution, in certain circumstances, can be determined, the Katanga district in particular offering interesting possibilities. In the air survey about to be undertaken there, Major Hemming thinks that the geologists will be able to locate copper ore deposits by the soil effect on vegetation, the distribution of which will be revealed by the air photographs.

Other possibilities of aircraft are under observation, as in the revision of the O.S. 1/2500, commonly called the 25-inch map, for south-east England. The Director-General of the Ordnance Survey, in discussing the official maps at present available to the public, indicated certain developments in the 1/1,000,000 map of England and Wales. Additional contours, a revision of the towns and certain other details, will enhance its value for general use, whilst the success of the map showing Roman roads encourages the Ordnance Survey to proceed with similar maps of an archæological and historical character. A special map has been prepared showing the track in Britain of the total solar eclipse which takes place on June 29 next, a phenomenon not to be repeated here until the year 1999. In this connexion Prof. H. H. Turner described, by means of photographs of previous eclipses and by ingenious mechanical slides, the formation and nature of an eclipse.

A visit to East Kent included an excursion to the Betteshanger Colliery and the housing schemes at Elvington and Aylesham. The latter, serving the needs of the Snowdown and Adisham Collieries, may be taken as the best expression of an attempt to save the beauty of the Kentish countryside in face of a possible industrial development. In the valley below Aylesham Wood, Nature offers a site for a town of ten thousand inhabitants which gives the planner of towns, both in the form and the setting of the valley, his maximum opportunity. The collieries, though less than a mile away, are effectively hidden by rising ground, the summit of which, crowned by woods and spinneys, forms an effective horizon. This Aylesham scheme is a striking application of geographical science to the economic and social needs of our times. It is one in which the unconscious and empirical adjustment due to slow growth and lack of policy—illustrated by Mrs. Ormsby's regional survey of London—may be replaced by a sound but not too rigid plan of organised urban development.

The Proposed New Biological Station in Bermuda.

WE have recently received from Prof. Herbert W. Rand, of Harvard University, a statement setting forth the history of the Bermuda Biological Station and the steps which are being taken for its reorganisation with the view of placing it on a permanent foundation and of extending its usefulness.

The station was inaugurated in 1903 through the joint activities of Profs. C. L. Bristol (New York) and E. L. Mark (Harvard), and since that time about 250 workers have carried out investigations at the station, and 141 published papers have been issued.

In August 1925 a group of American biologists interested in the Bermuda Station met to consider its future, and proposed a scheme for its complete reorganisation on the same general lines as those which have proved so successful in the case of Wood's Hole. The first step was to communicate with biologists who had either worked in Bermuda or for other reasons might be expected to be interested in the work of the station, and replies from about 150 were received, and these biologists form the corporation. They were asked to nominate a committee of reorganisation, which met in New York in Nov. 1925. Recognising the importance of securing the co-operation and support of the Bermudians, this committee sent letters to the Governor of Bermuda, to former members of the Bermuda Natural History Society, and to several other residents of the island. The responses are stated to be most encouraging. The committee arranged for the election, by ballot of the members of the corporation, of a board of twelve trustees, and it was provided that four of these should be non-residents of the United States. These are Dr. E. J. Allen, Plymouth; Prof. J. H. Ashworth, Edinburgh; Dr. A. G. Huntsman, Director of the Atlantic Experimental Station for Fisheries, Halifax, Canada; and Dr. E. A. McCallan, Director of Agriculture, Bermuda. The American trustees are Prof. E. G. Conklin, Dr. E. V. Cowdry, Dr. C. B. Davenport, Profs. B. M. Duggar, R. A. Harper, R. G. Harrison, E. L. Mark, and H. W. Rand.

Papers of incorporation under the laws of the State of New York have been prepared and approved, so that the station is authorised to accept and hold funds to establish and maintain a station for scientific study in biology. A committee is investigating the possible sites for the new station and is drawing up the detailed plans for the station and its equipment.

It is hoped that the government of Bermuda may be willing to make some provision for the station, possibly in connexion with the new aquarium now in course of construction. The Royal Society of London has intimated its interest in the scheme to widen the scope and value of a station offering such exceptional advantages of position, which, though situated in British territory, has hitherto owed its existence and development to American enterprise, and the National Research Council at Washington has passed a vote approving the project.

We understand that, when the organisation is completed, there is every hope that funds to a substantial amount will be forthcoming from America to put the station upon a sound financial basis and to make it a first-class laboratory with thoroughly adequate equipment. British marine biologists will, we are sure, follow with sympathetic interest the efforts of the committee to this end. The advantages of the Bermudas for biological research are considerable; the semi-tropical fauna can be studied under reasonable conditions of living and of climate throughout the year, and the station will be readily accessible, being reached in about forty-eight hours from New York. A well-equipped station in the Bermudas will afford the opportunity for the proper investigation of the semi-tropical waters of the Atlantic, and in these studies it is hoped British and American scientific men will be associated. We cordially wish the committee success in its endeavours to provide the means for the furtherance of this important work in marine biology.

University and Educational Intelligence.

CAMBRIDGE.—A. R. Clapham, Downing College, has been appointed to the Frank Smart University studentship in botany.

DR. GEORGE McOWAN, lecturer in chemistry in the United College of St. Salvator and St. Leonard, University of St. Andrews, has been appointed reader in chemistry at Raffles College, Singapore.

A REPORT on Higher Degrees has been issued by the Association of University Teachers as a supplement to the *University Bulletin*, vol. 6, No. 1. It represents the results of the labours of a committee of the Association appointed to inquire into the conditions under which higher degrees are awarded in the universities of Great Britain. Several years ago a similar inquiry was undertaken by the Universities Bureau of the British Empire, and summaries of the conditions have since been published in the "Universities Year-book." The committee of the A.U.T., however, has not rested content with recording existing conditions, but has fitted its record into a convenient tabular form, and has gone so far as to formulate general principles and even to suggest standard regulations which it commends to the careful consideration of the universities on the ground that, if some common agreement could be achieved, it would be to the great advantage of university study and research. The general principles recommended are: that the D.Litt. and D.Sc. should imply conspicuous ability and originality and distinguished and sustained achievement; the Ph.D., ability to study a problem systematically and to relate results to the general body of knowledge of the subject, and a definite contribution to knowledge or scholarship; and the degree of Master, the mastery of the technique of investigation. The suggested regulations include a *viva voce* examination for the Ph.D. and for the Master's degree. Standardisation is not a word to conjure with in university circles, but this report seems to deserve the consideration it asks for.

Calendar of Discovery and Invention.

January 23, 1710.—Johann Friedrich Böttger, the German alchemist, was born in 1682 and died in 1719. Apprenticed to a chemist of Berlin named Zorn, he experimented with zest with the view of the transmutation of metals into gold. From Berlin he went to Dresden, and it was while under the patronage of the Elector of Saxony that he accidentally discovered the process of making porcelain from the reddish clay found in the neighbourhood of Meissen, and on Jan. 23, 1710, the first European porcelain factory was opened at that place.

January 24, 1838.—During the voyage from Europe to America in the sailing vessel *Sully* in 1832, the American painter, Morse, then forty-one years of age, conceived the idea of signalling by electricity, using a code of dots and dashes. Six years later, on Jan. 24, 1838, he exhibited his electric telegraph in New York city, the *Journal of Commerce* stating: "Intelligence was instantly transmitted through a circuit of ten miles, and legibly written on a cylinder at the extremity of the circuit."

January 25, 1868.—Bishop Thirlwall, writing on Jan. 25, 1868, said: "I had a treat last night, which I would not have missed for any prize. Tyndall delivered the second (the first unhappily on the Friday before) of the lectures at the Royal Institution, 'On Faraday as a Discoverer.' . . . Tyndall said many fine things, not flowers of rhetoric, but springing out of the depths of their long intimate friendship. . . . He prized the honour of being Faraday's successor less than the happiness of having been his friend. The one was a mantle almost too heavy to bear, the other a memory full of the purest delight. He closed with the words, 'Let me die the death of the noble, and let my last end be like his,' and then rushed out of the room amidst a storm of applause. The attendance was just the largest that the room, with the addition of extra chairs, would hold. It was curious to see how, after it was over, people gave vent to their feelings by shaking hands, as if to congratulate one another on being present on such an occasion. It was indeed something to remember to the end of one's life. Faraday was a noble man, with heart, mind, and soul equally and healthily developed."

January 27, 1774.—One of the principal factors in engineering progress has been the development of machine tools. Among these the oldest is the lathe. A notable advance in workshop practice was made when John Wilkinson, on Jan. 27, 1774, patented his machine for boring guns in which the gun was rotated and the boring tool advanced down the bore. Called upon to make the cylinders for the engines of Watt, Wilkinson devised a machine in which the cylinder was fixed but the boring bar was supported at both ends while the cutter-head was moved along the bar, thus enabling the surface traced out by the tool to be reproduced in the work.

January 28, 1807.—Murdock in England and Le Bon in France were the pioneers of gas lighting, but its introduction for street lighting was due to the eccentric German, Winsor, through whose efforts Pall Mall was lighted by gas on Jan. 28, 1807. This was the first public thoroughfare in the world to be so illuminated.

January 29, 1886.—It was the invention of the light, high-speed spirit engine by Daimler which made the motor-car possible, but the first to apply such engines to carriages was Karl Benz. Benz's first motor-car, built in 1885, is in the Deutsches Museum, Munich; his patent is dated Jan. 29, 1886.

E. C. S.

Societies and Academies.

LONDON.

Royal Society, Jan. 13.—**F. W. R. Brambell, A. S. Parkes,** and **Una Fielding:** Changes in the ovary of the mouse following exposure to X-rays. Part i. Irradiation at 3 weeks old. Degeneration occurred of all oocytes in the ovaries of 47 female mice, exposed to full sterility dose of X-rays at 3 weeks old. Membrana granulosa and theca interna, in those cases where differentiated, degenerate also. Finally old follicles are only represented by small cavities containing zona pellucida remnants. Simultaneously with these changes, old inter-follicular tissue atrophies, and germinal epithelium proliferates epithelial cords. In adult animals ovaries are composed almost entirely of this first proliferation. In many cases a second proliferation follows. This consists of small spherical or slightly elongated cords. These cords resemble so-called spermatic cords described in ovaries of inbred rabbits and of free-martin cattle. They also resemble structures described as anovular follicles. They have no effect on oestrous cycle.

F. W. R. Brambell, A. S. Parkes, and **Una Fielding:** Changes in the ovary of the mouse following exposure to X-rays. Part ii. Irradiation at or before birth. Investigation of the ovaries of 6 mice X-rayed *in utero* and of 30 X-rayed at birth confirm the foregoing results. Of animals irradiated at birth, 24 were allowed to become adult. Cords of first proliferation constituted the bulk of all the ovaries. The cells of first proliferation appear to be responsible for production of oestrin and regulation of oestrous cycle. Production of oestrin stops at certain stage of differentiation into luteal-like cells.

A. S. Parkes: On the occurrence of the oestrous cycle after X-ray sterilisation. Part ii. Irradiation at and before birth. Further evidence is brought forward in support of conclusion that all normal cyclic oestrous phenomena except ovulation can occur in animals in which Graafian follicles of ovary have been totally destroyed at an early age by exposure to X-rays, and can occur, therefore, in the absence of organised corpora lutea and Graafian follicles.

R. M. Sargent: Recovery from vigorous exercise of short duration. Recovery from vigorous exercise of short duration is extremely rapid, especially in the first 10 minutes immediately after cessation of exercise. Rate of recovery varies somewhat with the subject and the severity and duration of exercise. It is inadvisable, in determining total recovery-oxygen after exercise, to measure the amount used during the period of incomplete recovery and apply a correction. As a result of exercise, oxygen consumption at rest was found to be increased, on average about 7 per cent. This change appears to result from genuine alteration in level of metabolism, and cannot be regarded as an integral part of recovery process as such.

R. G. Canti and **M. Donaldson:** The effect of radium on mitosis *in vitro*. It is possible to bring about cessation of mitosis in tissue cultures *in vitro* by means of radium irradiation. With the intensity of radium irradiation employed, mitosis ceases, but when the radium is removed after several hours' exposure, mitosis reappears. At commencement of irradiation, cells not only complete division when mitosis has already commenced, but some cells also actually begin mitosis and go through the process of division in apparently normal fashion. In no experiment was there any evidence of radium producing increase in the number of cells in mitosis.

R. J. Ludford and **W. Cramer:** Secretion and the Golgi apparatus of Islets of Langerhans. Appearances in the cells of the Islets of Langerhans in normal animals indicate that the cells in the same animals are at different stages of functional activity. The condition in which the most definite and uniform change has been observed is during pregnancy, in which the Islet cells are particularly active. Similar but less uniform and definite change is found after exposure of heat.

M. Dixon: On the mechanism of oxidation-reduction potential. The phenomena of oxidation-reduction potential can be predicted from the work of Wieland, and a theory in accordance with Wieland's theory of oxidation is developed and extended in various directions. An explanation of the anomalous behaviour of the sulphydryl system is suggested.

Royal Meteorological Society, Dec. 15.—**N. K. Johnson**: Some meteorological observations made at sea. Readings were taken over a period of 24 hours on a ship steaming eastwards in the Mediterranean Sea. The observations were made on May 12-13, 1926, and the sky was practically clear throughout. Air temperature showed a diurnal variation of 1°·9 F. There are also indications of a small diurnal variation in the sea temperature. The vertical temperature gradient between heights of 5 m. and 22 m. was found to possess the dry adiabatic value throughout the day but exceeded this value during the night. This result, which is exactly the reverse of what occurs on land, probably represents the normal occurrence at sea.—**N. K. Johnson** and **E. L. Davies**: Some measurements of temperature near the surface in various kinds of soil. Measurements were made throughout 1925 of the maximum and minimum temperatures recorded at a depth of about 1 cm. below the surface of six kinds of 'soil'. In summer the maximum soil temperatures are considerably in excess of the maximum air temperatures recorded in a Stevenson screen. This excess is 37° F. in the case of tarmac, and 14° F. in the case of grass-covered soil. In mid-winter the soil maxima are all practically equal to the screen maximum. The minimum temperatures recorded in the 'soils' agree closely throughout the year with the minimum air temperature in the screen. The only exception is in the case of the grass-covered soil, in which the minimum averages about 5° F. higher than the air minimum. Using a value for soil conductivity, the temperature observations were extrapolated up to the actual surface of the soil. In this way it is found that the average summer maximum for the surface of tarmac is about 115° F., and for earth and sand about 100° F. The extreme maxima for these 'soils' are calculated as about 140° F. and 130° F. respectively. In the tropics an extreme maximum surface temperature for ordinary soils may be estimated as about 180° F.—**A. N. Puri**: Investigation on the behaviour of hair hygrometers. A study has been made of four types of hair hygrometers in which the total load on the hairs consists of a weight. These were taken through a series of humidity changes controlled by sulphuric acid–water mixtures. When the hair is loaded with a weight of two grams or more, it undergoes a slow extension which extends over a period of several weeks. Hair under a smaller load gives readings which can be reproduced to measure humidity within 2 per cent. Alterations in the length of the hair due to changes in humidity show a hysteresis effect which is apparently in the reverse direction to that observed when measurements are taken in terms of change in weight.

DUBLIN.

Royal Irish Academy, Dec. 13.—**A. Farrington**: The topographical features of the granite-schist junction in the Leinster chain. The zone of metamorphic rock which surrounds the Leinster granite is more resistant to weathering than the granite and tends to form high ground at the margin of the latter. This is particularly well shown in the basin of the Slaney river, where an undulating plain of granite is shut in on three sides by high hills of schist. The valleys of the streams which flow out of the granite area are constricted where they cross the schist belt, and as a result of this narrowing the glacially eroded glens of the eastern slope of the Leinster chain are much overdeepened in the schist, a well-marked step being formed near the granite-schist junction.

Royal Dublin Society, Dec. 21.—**J. Reilly** and **Joan Sullivan**: Studies on peat (Part ii.). Distillation under reduced pressure of certain constituents of peat.—**J. Reilly** and **C. Boyle**: The production of essential oils from fresh-grown plants (Part ii.). The cultivation of *Mentha piperita* and further experiments on the winning of lavender oil.—**J. Reilly** and **J. Taylor**: (Part iii.). Oil of peppermint.—**J. Reilly** and **P. J. Drumm**: (Part iv.). Note on oil of camomile.—**W. R. Fearon**: Colour reactions associated with liver oils. Two classes of colour reactions are frequent in liver oils: (1) those obtained directly on the addition of a powerful condensing agent, such as sulphuric acid, arsenic trichloride, or phosphorus pentoxide; and (2) those obtained indirectly on the addition of an aromatic phenol before treatment with the condensing agent. Reactions of the first class appear to be intimately associated with the growth vitamin A. Reactions of the second class are independent of the vitamin, and are due to a saponifiable component of the oil.

EDINBURGH.

Royal Physical Society, Dec. 20.—**D. Guthrie**: Tattooing and its significance.—**D. J. Jackson**: The life-history of a braconid parasite of Sitona.—**A. C. Chaudhuri**: The erythrocyte count in sexually normal and abnormal fowls. The count is higher in males than in females, and is lower in castrated individuals than in normal. It is exceptionally low in hens with an extra ovary, while in cases of sex reversal it approaches that of the male.

MANCHESTER.

Literary and Philosophical Society, Nov. 30.—**Kenneth M. Smith**: Observations on some insect carriers of potato virus disease. The so-called 'virus diseases' of the potato are becoming a serious menace to the potato-growing industry of the world. The causal organism, if such there be, of this group of disorders has not yet been isolated. The diseases, however, particularly in their 'leaf-curl' and 'mosaic' forms, are known to be infectious, and in Nature are transmitted by certain insects. A number of insects which attack the potato plant have been tested under controlled conditions as to their disease-carrying abilities. The insect is first itself contaminated with the disease, and later is placed upon a potato plant under an insect-proof cage. This plant is produced by one half of a known healthy tuber, the other half tuber being grown under a separate insect-proof cage as a control. So far as results of the experiments up to 1925 go, they indicate that the aphis or certain species of aphis are the most efficient carriers of the mosaic disease of the potato. Successful inoculation was also achieved with other species of insects, in two cases with a leaf-hopper and also with the greenhouse white-fly (Aleurodes). The capsid bugs have so far failed to transmit mosaic disease.

PARIS.

Academy of Sciences, Dec. 6.—**H. Andoyer**: The method of Delaunay.—**F. E. Fournier**: General laws, unpublished, of the formation of the vertical undulatory profile of the satellite wave of a ship in motion, calm sea.—**J. Costantin**: New experimental results on the culture of *Pleurotus Eryngii*.— — **Piquier**: The general integration of the partial differential equation $s=f(x, y, z, q)$.—**Bertrand Gambier**: The deformation of surfaces and the Gauss-Codazzi equations.—**Paul Montel**: The domains corresponding to values of analytical functions.—**G. Vranceanu**: The absolute differential calculus for non-holonome varieties.—**J. Delsarte**: The study of certain integral equations which generalise those of Fredholm.—**H. Mineur**: The absolute differential calculus.—**E. M. Antoniadi**: Changes observed on the planet Jupiter. Details of further results obtained in 1926 at Meudon with the 83 cm. telescope. Illustrations of the appearances on Nov. 27, 1923, and July 1, 1913, are given. The conclusion is drawn that while in certain cases the sun may have an effect, the phenomena presented by Jupiter are for the most part inherent in the planet itself and are due to its high temperature.—**P. Helbronner**: Results of the direct geodesic junction of Corsica to the French continent.—**Jean Chazy**: The formula of the Doppler-Fizeau effect in the universe of de Sitter.—**Jean Rey**: The industrial utilisation of the energy of a warm liquid in a steam turbine. An account of an actual application in 1904 of the recent suggestion of G. Claude (*C.R.* 1926, p. 924).—**V. Posejpal**: The resonance absorption and yield of fluorescence in the domain of the X-rays.—**Edgar Pierre Tawil**: The variations of the optical properties of piezo-electric quartz submitted to high-frequency currents.—**Albert Pérard**: Study of the monochromatic cadmium radiations in Michelson and Hamy lamps from the point of view of their metrological applications.—**Paul Mondain-Monval**: The heats of mixing of partially miscible pairs (of liquids). The system methyl alcohol–cyclohexane. The heat absorbed per gram of mixture is shown graphically as a function of the percentage of cyclohexane. Curves for the temperatures 18°, 29°, 40°, and 52° C. are given, the latter being above the critical miscibility temperature.—**René Delaplace** and **Neda Marinesco**: Some physico-chemical properties of cæsium eosinate. Data are given for the number of dipoles of solvent fixed on the molecule, *p*H of aqueous solution, electrical conductivity, and molecular weight.—**Eugène Pérot**: The cementation of mild steel by cyanogen and by cyanamide. Curves are given showing the influence of temperature, time, and pressure (of the cyanogen).—**Georges Darzens**: A method of preparation of α substituted valerolactones. Alkylalkylacetic acids, a general method for the preparation of which is given, on heating to 90° C. with double their weight of 90 per cent. sulphuric acid, are converted into the α alkylvalerolactones.—**M. Tiffeneau** and **Mlle. J. Lévy**: The reality of the semipinacolic transposition: the comparative stability of the secondary and tertiary hydroxyl groups. The work of Daniloff on the transposition of trisubstituted aldehydes into ketones by the action of concentrated sulphuric acid throws some doubt on the reality of the semipinacolic transposition. Experiments on the dehydration of phenyldibenzl-, anisyldibenzyl-, and phenylethyl methyl-glycols, however, prove that there are real cases of semipinacolic transposition.—**R. Fosse**: The presence of allantoic acid in *Phaseolus vulgaris*. The presence of allantoic acid and the absence of uroxanic acid in this plant has been proved.—**L. Longchambon**: The constitution of chalcedonies and quartzines.—**René Souèges**: The embryogeny of the Papaveraceæ. The last stages of the development of the embryo in *Papaver Rhoeas*.—**A. Demolon** and **E. Natier**: The action of potassium chloride upon non-calcareous soils.—**M. Doyon** and **I. Vial**: The remarkable activity and nuclear origin of an anti-coagulating substance extracted from the mesenteric ganglia.—**Raymond Hamet**: The antagonism of atropine and adrenaline.—**P. Portier** and **Mlle. de Rorthays**. Researches on the load supported by the wings of Lepidoptera of different families.—**Maurice Azema**: The formation of the renal vesicles and the development of the kidney in *Ascidia mentula*.—**Edouard Chatton** and **André Lwoff**: The Synophrya, infusoria internally parasitic in crabs. Their evolution and place in the Fœttingeriidæ.—**J. Wolff** and **J. Loiseleur**: The biochemical oxidation of ferrous malate.—**Gabriel Bertrand**: Observations on the nature of ferrase and of certain oxydase systems with reference to the preceding paper.—**A. Philibert** and **J. Risler**: The action of neon light on bacteria.—**E. Brumpt**: The transmission of *Treponema crociduræ* by two species of Ornithodorus (*O. moubata* and *O. Marocanus*).

CALCUTTA.

Asiatic Society of Bengal, Dec. 6.—**T. V. Ramakrishna Aiyer**: Notes on some Indian Lepidoptera with abnormal habits. Examples of moths or butterflies living in association with other insects seem comparatively rare. Some examples, mainly from South India, are: Butterflies—*Spalgius epius*, West; moths—various species of the noctuid genus Eublemma; family Epipyropidæ.—**D. N. Majumdar**: (1) The bigonial breadth of some Hos of Kolhan; (2) Death and connected ceremonies of the Hos of Kolhan and Singbhum.—**Rev. H. Hosten, S.J.**: (1) Fr. N. Pimenta's Annual Letter, Goa, Dec. 21, 1599. The history of contemporary events drawn from the early missionary reports. (2) Fr. N. Pimenta, S.J., on Mogor, Goa, 1st Dec. 1600. (3) Fr. N. Pimenta's Annual of Margaõ, Dec. 1, 1601. (4) Three letters of Fr. Joseph de Castro, S.J., and the last year of Jahāngir, Aug. 24, 1626–Aug. 15, 1627. (5) Eulogy of Father Jerome Xavier, S.J., a missionary in Mogor, 1549–1617. (6) Some letters of Fr. Jerome Xavier, S.J., to his family, 1593–1612. (7) Some notes on Bro. Bento de Goes, S.J., 1583–1607.—**Mohini Mohan Chatterji**: (1) Brahmanism in Bengal. Gauda or Bengal from remote antiquity to modern times has contributed a distinct religious note, that of the combination of loyalty to Brahmanism with tolerance and universalism. (2) A study of some Bengali customs: (i) Survivals of group-marriage; (ii) Mock-marriage.

VIENNA.

Academy of Science, Nov. 25.—**R. Weiss** and **P. Fastmann**: Benzalaryl-phthalane and -naphthalane and the transformation of the former into di-substituted indone.—**E. Späth** and **A. Burger**: Opium alkaloids (vii.). Synthesis of laudanin and laudanidin.—**R. Seka, O. Schmidt**, and **K. Sekora**: Condensation products of pyro-mellithic acid anhydride.

WASHINGTON.

National Academy of Sciences (*Proc.*, vol. 12, No. 11, Nov.).—**Leonard B. Loeb**: Gas ion mobilities in ether-hydrogen mixtures. Measurements were made over the whole range of mixtures, 0–100 per cent. ether. At concentrations greater than 30 per cent. of ether the mobilities of both the positive and the negative ions follow the theoretical law of mixtures; with smaller concentrations the mobilities of the positive ions are abnormal, possibly suggesting the formation of labile clusters of ions.—**Roy. J. Kennedy**:

A refinement of the Michelson-Morley experiment (*v.* NATURE, Jan. 8, p. 64).—Paul S. Epstein: (1) On the evaluation of certain integrals important in the theory of quanta. A convenient expression is obtained for the integral which determines the matrix of the hydrogen atom, considering only the simple closed Kepler motion and neglecting relativity effect and spin of the electron. (2) The new quantum theory and the Zeeman effect.—R. M. Langer: The dispersion of atomic hydrogen. (1) A measure. A powerful discharge was passed through one tube of a pair constituting an interferometer containing hydrogen through which 'white-light' fringes were being observed. The shift of fringes at a given wave-length, together with the concentration of atomic hydrogen and index of refraction of molecular hydrogen, enables the dispersion of atomic hydrogen to be calculated. At about $\lambda = 6000$ Å.U., $\mu = 1{\cdot}000068$. The method involves certain assumptions, but is regarded as giving results of the right order. (2) A calculation. Attempts to adjust earlier dispersion formulæ to give the proper frequencies for anomalous dispersion lead to values of the index of refraction different from that obtained above.—H. B. Goodrich: The development of Mendelian characters in *Aplocheilus latipes*. There are four homozygous types of this Japanese freshwater fish: wild, yellow, white, and variegated. The colours are produced by three kinds of pigment cell, melanophores and brown and yellow chromatophores, which appear to be present in similar numbers in all four types and at the earliest stages of growth. The Mendelian gene appears to function by controlling the amount of melanin elaborated in cells which are always present.

Official Publications Received.

BRITISH AND COLONIAL.

Indian Problem and its Solution: a Letter by the Head of the Ahmadiyya Community to His Excellency the Viceroy and Governor-General of India. Pp. 31. (London: The London Mosque, Southfields, S.W.18.)

Transactions of the Buteshire Natural History Society (1926). Pp. 60+48 plates. (Glasgow and London: The Mann Publishing Co., Ltd.)

Aeronautical Research Committee: Reports and Memoranda. No. 1032 (M. 39): Some further Experiments on the Behaviour of Single Crystals of Aluminium under Reversed Torsional Stresses. By H. J. Gough, S. J. Wright and Dr. D. Hanson. Work performed for the Engineering Research Board of the Department of Scientific and Industrial Research. (B.1.a. Metals, 47.—T. 2166.) Pp. 13+8 plates. 1s. 3d. net. No. 1033 (Ae. 226): On the Advantages of an Open Jet Type of Wind Tunnel for Airscrew Tests. By H. Glauert and C. N. H. Lock. Pp. 10+3 plates. 9d. net. (London: H.M. Stationery Office.)

Address on 'The Dangers of Contraception,' delivered by Frederick J. McCann at the Caxton Hall, London, on October 29th, 1926. Pp. 16. (London: League of National Life.) 6d.

The Marine Biological Station at Port Erin (Isle of Man): being the Fortieth Annual Report of the former Liverpool Marine Biology Committee, now the Oceanography Department of the University of Liverpool. Drawn up by Prof. Jas. Johnstone. Pp. 39. (Liverpool: University Press of Liverpool, Ltd.; London: Hodder and Stoughton, Ltd.) 1s. 6d. net.

The British Mycological Society. Transactions, Vol. 11, Parts 3 and 4, December. Edited by Carleton Rea and J. Ramsbottom. Pp. 169-311. (London: Cambridge University Press.) 15s. net.

New Zealand. Department of Lands and Survey: Scenery-Preservation. Report for the Year ended 31st March 1926, together with Statement of Accounts and Schedule of Lands Acquired and Reserved during the Year under the Scenery Preservation Act. Pp. 8. (Wellington, N.Z.: W. A. G. Skinner, 1926.) 6d.

Western Australia: Geological Survey. Bulletin No. 88: Palæontological Contributions to the Geology of Western Australia. Series 7, Nos. 13, 14 and 15. By Rev. W. Bretnall, F. Chapman and Ludwig Glauert. Pp. 72 (4 plates). Bulletin No. 91: The Auriferous Lodes of the Gibraltar District, Coolgardie Coalfield By F. R. Feldtmann. Pp. 29+7 plates. (Perth: Fred. Wm. Simpson.)

Memoirs of the Department of Agriculture in India. Entomological Series, Vol. 9, No. 6: Studies on Indian Thysanoptera. By H. H. Karny. Pp. 187-220+plates 16-23. 1.8 rupees, 2s. 6d. Entomological Series, Nos. 7, 8, 9. No. 7: New Species of Indian Gall Midges (Itonididæ), by Dr. E. P. Felt; No. 8: New Indian Geometridæ, by Lewis B. Prout; No. 9: Description of *Laspeyresia sirpicola*, n.sp. (Lepidoptera), by E. Meyrick; with a Short Note on the Life-History and Status, by Rai Bahadur C. S. Misra. Pp. 241-260+plate 24. 5 annas; 6d. (Calcutta: Government of India Central Publication Branch.)

Proceedings of the Royal Society of Edinburgh, Session 1925-1926. Vol. 46, Part 3, No. 28: Researches into the Characteristic Numbers of the Mathieu Equation (Second Paper). By Dr. E. L. Ince. Pp. 316-322. 9d. Vol. 46, Part 4, No. 29: On the Cardinal Function of Interpolation-Theory. By W. L. Ferrar. Pp. 323-333. 1s. (Edinburgh: Robert Grant and Son; London: Williams and Norgate, Ltd.)

Proceedings of the Thirteenth Indian Science Congress (Bombay, 1926). Pp. xxiii+406. (Calcutta: Asiatic Society of Bengal.)

Records of the Botanical Survey of India. Vol. 9, No. 5: Mosses collected in Gilgit, etc., by J. Garrett and W. Lillie. By H. N. Dixon. Pp. 303-312+1 plate. (Calcutta: Government of India Central Publication Branch.) 8 annas; 10d.

FOREIGN.

Proceedings of the United States National Museum. Vol. 69, Art. 12: New Land and Fresh-Water Mollusks from Central and South America. By William B. Marshall. (No. 2638.) Pp. 12+3 plates. (Washington, D.C.: Government Printing Office.)

Instituto Geográfico y Catastral. Anuario del Observatorio Astronómico de Madrid para 1927. Pp. 528. (Madrid.)

The Rockefeller Foundation. Annual Report, 1925. Pp. xi+521 (43 plates). (New York City.)

Department of Commerce: Bureau of Standards. Technologic Papers of the Bureau of Standards, No. 325: Recent Developments in Lamp Life-Testing Equipment and Methods. By J. F. Skogland and E. P. Teele, Jr. Pp. 681-702+5 plates. (Washington, D.C.: Government Printing Office.) 15 cents.

Smithsonian Institution: United States National Museum. Bulletin 100, Vol. 6, Part 2: Contributions to the Biology of the Philippine Archipelago and Adjacent Regions. Additions to the Polychætous Annelids collected by the United States Fisheries Steamer *Albatross*, 1907-1910, including one New Genus and three New Species. By A. L. Treadwell. Pp. 181-196. (Washington, D.C.: Government Printing Office.)

Proceedings of the United States National Museum. Vol. 69, Art. 8: Crustaceans of the Orders Euphausiacea and Mysidacea from the Western Atlantic. By Walter M. Tattersall. (No. 2634.) Pp. 35+2 plates. Vol. 69, Art. 23: Cymbidium, a New Genus of Silurian Pentameroid Brachiopods from Alaska. By Edwin Kirk. (No. 2649.) Pp. 5+1 plate. (Washington, D.C.: Government Printing Office.)

New York Academy of Sciences. Scientific Survey of Porto Rico and the Virgin Islands. Vol. 4, Part 1: Geology of the Virgin Islands, Culebra and Vieques. Introduction and Review of the Literature, by James F. Kemp; Physiography, by Howard A. Meyerhoff. Pp. 141. (New York City.)

Appendix No. 2 to the Annual Report of the Chief of the Bureau of Navigation, 1926: Annual Report of the Naval Observatory for the Fiscal Year 1926. Pp. 19. (Washington, D.C.: Government Printing Office.)

Journal of the Faculty of Science, Imperial University of Tokyo. Section 2: Geology, Mineralogy, Geography, Seismology. Vol. 2, Part 1: The Tanna Earthquake of 1925. By Dr. Bundjirô Kotô. Pp. v+75+8 plates. (Tokyo.) 2.50 yen.

CATALOGUES.

The Book: its Authors, Printers, Illustrators and Binders; also a Selection of Memoirs and Autograph Letters of Literary Personalities. (No. 490.) Pp. 60. (London: Francis Edwards.)

Classified List of Second-hand Scientific Instruments. (No. 89.) Pp. vi+58. (London: C. Baker.)

Heat Treatment Bulletin No. 37: Theory and Practice in the Hardening Shop. Pp. 5. (London: Automatic and Electric Furnaces, Ltd.)

Diary of Societies.

SATURDAY, JANUARY 22.

BRITISH MYCOLOGICAL SOCIETY (in Botanical Department, University College), at 11 A.M.—W. Buddin and Miss E. M. Wakefield: Studies on *Rhizoctonia Crocorum* and *Helicobasidium purpureum*.—E. W. Mason: On the Naming of a Dark Spored Hyphomycete.—J. Ramsbottom: Fragmenta Mycologica V.—Miss K. Sampson: Anthracnose Diseases of Red Clover.—R. C. Woodward: Studies on Apple Mildew.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. E. W. Tristram: English Medieval Wall-Painting.

PHYSIOLOGICAL SOCIETY (at National Institute for Medical Research, Hampstead), at 2.30.—Demonstrations by Prof. L. Hill: Measurement of Capillary Pressure in the 3rd day Chick-Embryo.—J. A. Campbell: Chamber for Continuous Exposure to High and Low Percentage of Oxygen.—T. Angus: Apparatus for Studying the Arc-lamp as a Source of Ultra-violet Radiations.—H. W. Dudley: Apparatus for Working up Tissue-extracts on an Intermediate Scale.—Dr. H. H. Dale and A. N. Richards: Continuous Record of Oxygen Absorption by Small Animals.—W. Feldberg: Histamine Vasodilatation in the Rabbit.—R. Bodo and H. P. Marks: Aseptic Perfusion of Isolated Heart.—Papers by Prof. H. S. Raper: Indole Derivatives from Tyrosine.—Dr. G. V. Anrep and R. Kinosita: The Influence of Mechanical Factors of the Circulation upon the Diastolic Volume of the Ventricles.—Prof. R. J. S. McDowall: The Relation of Alkali to the Parasympathetic (Preliminary Communication).—M. A. Battie and Prof. R. J. S. McDowall: The Effect of Alkali on the Blood Sugar.—K. Furusawa and P. M. T. Kerridge: The Buffering Power of the Uterus of the Cat.—J. A. Campbell: Effects of Exposure to Low Tensions of Air and Oxygen.—C. H. Best, Dr H. H. Dale, H. W. Dudley, and W. V. Thorpe: Histamine, the Vasodilator Principle of Extracts from the Lung.—Dr. H. H. Dale and A. N. Richards: The Vasodilator Action of Small Doses of Adrenaline.—Prof. L. Hill: The Biologically Active Rays of Sunlight.—Dr. G. A. Clark: The Immediate Effect of Vagus Section on Blood-Sugar Level.—E. M. Boock, J. H. Burn, and

J. W. Trevan: The Accuracy of the Assay of Strophanthus and Squill by Different Methods.—J. H. Burn and J. M. Ellis: The Amount of Specific Alkaloid in Different Samples of Ergot, assayed by Clark's Method.

Hull Association of Engineers (at Hull Municipal Technical College), at 7.15.—G. F. O'Riordan: A Two Years' Retrospect.

MONDAY, January 24.

Royal Irish Academy, at 4.15.

Royal Society of Edinburgh, at 4.30.—A. R. Normand, J. D. Ross, and E. Henderson: The Distribution of Intensity in the X-Ray Spectra of the Normal Saturated Dicarboxylic Acids, their Diethyl, and Mono-Ethyl Esters.—W. J. McCallien: The Geology of Gigha.—Prof. H. Briggs: Rock-Faulting from the Engineering Standpoint.

Institution of Automobile Engineers (Loughborough Graduates' Meeting) (at Loughborough College), at 7.—Mr. Short: Carburettors.

Institution of Electrical Engineers (Informal Meeting), at 7.—M. Whitgift and others: Debate on The Electricity Bill.

Institution of Electrical Engineers (Mersey and North Wales (Liverpool) Centre) (at Liverpool University), at 7.—J. Firth and F. Buckingham: The Electrical Equipment of Large Buildings.

Institution of Electrical Engineers (North-Eastern Centre) (at Armstrong College, Newcastle-upon-Tyne), at 7.—Col. E. Mercier: Notes on the 60,000-Volt Underground Network of the Union d'Electricité.—P. Dunsheath: 33,000-Volt Cables with Metal-Sheathed Cores, with special reference to the S.L. Type.

Institution of Mechanical Engineers (Graduates' Section, London), at 7.—Major A. R. Valon: Mechanical Engineering in the Army in Relation to the Duties of an Ordnance Mechanical Engineer (Lecture).

Aristotelian Society (at University of London Club), at 8.—H. H. Price: Mill's Theory of the External World.

Royal Society of Arts, at 8.—Dr. L. C. Martin: Recent Progress in Optics (Cantor Lectures) (1).

British Medical Association, at 8.—Sir Berkeley Moynihan: Cancer and how to fight it (Hastings Lecture).

Royal Society of Medicine (Odontology Section), at 8.—Dr. J. H. Maclean: The Bacteriology of Dental Caries.—Prof. H. P. Pickerill: Non-eruption of Teeth.

Medical Society of London, at 8.30.—Pathological Evening.

Royal Geographical Society (at Æolian Hall), at 8.30.—J. M. Wordie: The Cambridge Expedition to East Greenland.

Institute of Chemistry (Leeds Area Local Section).—Prof. J. W. Cobb: The Training of a Fuel Chemist.

TUESDAY, January 25.

Royal Society of Arts (Dominion and Colonial Meeting), at 4.30.—B. H. Morgan: The Sugar Resources of the British Empire.

Royal Society of Medicine (Medicine, Surgery, and Laryngology Sections), at 5.—Dr. L. S. T. Burrell, Dr. F. Chandler, Dr. G. Marshall, and Dr. K. D. Wilkinson (*Medicine*), T. Edwards, J. E. H. Roberts, and H. S. Souttar (*Surgery*), G. E. Martin, C. A. S. Ridout, and V. E. Negus (*Laryngology*): Special Discussion on The Treatment of Chronic Non-tuberculous Infection of the Lungs.

Royal Institution of Great Britain, at 5.15.—Prof. R. Whytlaw Gray: Smokes as Aerial Disperse Systems (1).

Institution of Electrical Engineers (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—Prof. W. M. Thornton: What is Electricity? (Faraday Lecture).

Institution of Electrical Engineers (North-Western Centre) (Informal Meeting) (at Engineers' Club, Manchester), at 7.—J. H. Reyner: Recent Developments in Radio Reception.

Royal Photographic Society of Great Britain (Scientific and Technical Group), at 7.—Exhibition and Demonstration of Apparatus used in the Testing of Photographic Products, etc.:—Dr. F. C. Toy: A New Photo-electric Photometer.—S. O. Rawling: (*a*) An Electrode Vessel Jacketed for Use at Various Temperatures; (*b*) Method for Coating Photographic Emulsions as Single Layer Plates Without Dilution.—A. S. Newman: (*a*) A New Design of Microscope; (*b*) Apparatus for General Laboratory Use; (*c*) Sundry Workshop Appliances.—F. F. Renwick: A Turbidimeter for Use with Photographic Emulsions.—E. Farrow: An Apparatus for Determining the Relative Exposures with Various Light Filters.—R. Davies: A Selenium Cell Photometer Adapted for the Determination of Reflection Densities with an Automatic Curve Plotting Device.—T. Thorne Baker: Apparatus for the Telegraphic Transmission of Photographs, at Work over an Artificial Line Equivalent Electrically to Paris–London.—W. A. Balmain and L. F. Davidson: An Intensity Scale Apparatus Improved so as to render it possible to Expose Several Strips of Plates Simultaneously.

Institution of Engineers and Shipbuilders in Scotland (at 39 Elmbank Crescent, Glasgow), at 7.30.—Rev. R. R. Hyde: The Development of Industrial Welfare Work.

Royal Anthropological Institute (Anniversary Meeting), at 8.30.—H. J. E. Peake: The Beginnings of Civilisation (Presidential Address).

WEDNESDAY, January 26.

Newcomen Society for the Study of the History of Engineering and Technology (in Demonstration Room, A 1, Science Museum, South Kensington), at 5.30.—A. Titley: Trevithick and Rastrick and the Single Acting Expansive Engine.—Rhys Jenkins: A Note on Newcomen's Handwriting.

Institution of Automobile Engineers (North of England Centre) (at Engineers' Club, Manchester), at 7.—Prof. W. Morgan: The Optical Indicator as a Means of Examining Combustion in Internal-Combustion Engines.

North-East Coast Institution of Engineers and Shipbuilders (Graduate Section) (at Newcastle-upon-Tyne), at 7.15.—J. E. Conner: The Erection of a Rotary Portland Cement Kiln.

Institution of Automobile Engineers (Wolverhampton Centre) (at Engineering and Scientific Club, Wolverhampton), at 7.30.—G. Rushton: The L.G.O.C. Methods of Repairing Motor Omnibuses.

Society of Chemical Industry (South Wales Section) (at University College, Swansea), at 7.30.—Capt. J. R. Green: Quantitative Spectrographic Analysis in Metallurgy.

Royal Society of Arts, at 8.—F. W. Spencer: British and American Practice in Hot and Cold Working of Metals.

Faraday Society (at Chemical Society), at 8.—J. B. O'Sullivan: The Behaviour of the Quinhydrone Electrode in Solutions of Neutral Copper Sulphate.—W. Taylor: The Actinic Absorption of Chlorine Gas with Respect to the Hydrogen Chlorine Reaction.—W. Taylor and A. Elliott: The Residual Effect in the Actinic Absorption of Chlorine.—W. R. Harrison and E. P. Perman: Vapour Pressure and Heat of Dilution of Aqueous Solutions. Part II.—N. A. de Bruyne and R. W. W. Sanderson: The Electrostatic Capacity of Aluminium and Tantalum Anode Films.—G. A. Elliott, S. S. Joshi, and R. W. Lunt: On the Velocity of Chemical Reaction in the Silent Electric Discharge.—G. A. Elliott: The Activation of Hydrogen in the Electric Discharge.—C. C. Tanner: The Soret Effect.—H. I. Downes and E. P. Perman: An Improved Method of Measuring Vapour Pressure by Air Bubbling.

British Psychological Society (Medical Section) (at Royal Society of Medicine), at 8.—Dr. T. S. Good: An Attempt to Investigate and Treat Cases of Psycho-neuroses and Psychoses at an Out-Patient Clinic; followed by a discussion by Dr. E. Mapother, Dr. H. Crichton Miller, Dr. J. Rickman, and others.

Eugenics Society (at Royal Society), at 8.30.—H. Macdonald: Social Distribution of Intelligence.

Institution of Mechanical Engineers (Sheffield Branch) (at Sheffield).—B. W. Tipple: Machine Tools.

THURSDAY, January 27.

Royal Society, at 4.30.—L. A. Harvey: The History of the Cytoplasmic Inclusions of the Egg of *Ciona intestinalis* (L.) during Oogenesis and Fertilisation.—S. Dickinson: Experiments on the Physiology and Genetics of the Smut Fungi. Hyphal Fusion.—Dr. J. W. H. Harrison: Experiments on the Egg-laying Instincts of the Sawfly *Pontania salicis* Christ. and their Bearing on the Inheritance of Acquired Characters, with some Remarks on a New Principle in Evolution.—S. A. Asdell and Dr. F. H. A. Marshall: The Effect of the Ovarian Hormone in producing pro-Œstrous Development in the Dog and Rabbit.—E. Ponder: The Measurement of Percentage Hæmolysis. II.

Royal Institution of Great Britain, at 5.15.—J. R. H. Weaver: Romanesque and Early Pointed Architecture in Spain (2).

South London Entomological and Natural History Society, at 7.—Annual Meeting.

Institution of Automobile Engineers (Luton Graduates' Meeting) (at Luton), at 7.30.—G. L. Ensor: A Practical Experience of the Single Sleeve Valve Principle.

FRIDAY, January 28.

Royal Society of Arts (Indian Section), at 4.30.—Sir Leonard Rogers: The Forecasting and Control of Cholera Epidemics in India.

North-East Coast Institution of Engineers and Shipbuilders (at Newcastle-upon-Tyne), at 6.—G. S. Baker: The Economy of Tank Testing of Ship Forms and Research in Ship Propulsion.

Institution of Locomotive Engineers (Manchester Centre) (at College of Technology, Manchester), at 7.—S. Symes and others: Discussion on Mass Production as applied to the Repairing of Locomotives.

Royal Photographic Society of Great Britain, at 7.—H. Lambert: Lighting in Portraiture.

West of Scotland Iron and Steel Institute (at Royal Technical College, Glasgow), at 7.—Sir William Larke: Address.—Prof. A. L. Mellanby and Prof. W. Kerr: Use and Economy of High Pressures in Steam Plants.

Junior Institution of Engineers, at 7.30.—C. H. Atkinson: The Design of High Tension Sub-stations.

Royal Sanitary Institute (in Small Town Hall, Reading), at 7.30.—Discussion on Cancer:—Sir Stewart Abram: From the Point of View of the Physician and the Public Authority.—Dr. T. S. Keith: Cancer Research To-day.—J. L. Joyce: The Present Position of the Treatment of Cancer.

Royal Institution of Great Britain, at 9.—Prof. E. P. Cathcart: The Physique of Women employed in Industry.

Manchester Literary and Philosophical Society (Chemical Section).

SATURDAY, January 29.

North of England Institute of Mining and Mechanical Engineers (at Neville Hall, Newcastle-upon-Tyne), at 3.—P. F. Hope: Steam and Electric Locomotives for Colliery Purposes.

Royal Institution of Great Britain, at 3.—Prof. E. W. Tristram: English Mediæval Wall-Painting (1).

PUBLIC LECTURES.

SATURDAY, January 22.

Horniman Museum (Forest Hill), at 3.30.—Mrs. H. M. Dunn: Benares, the Sacred City.

SUNDAY, January 23.

Guildhouse (Eccleston Square), at 3.30.—S. N. Mallik: Hinduism.

MONDAY, January 24.

University College, at 6.—Dr. H. D. Jennings White: Science and Poetry.

THURSDAY, January 27.

King's College, at 5.30.—Dr. F. A. P. Aveling: The Mind: Psychology.

Northampton Polytechnic Institute, at 7.—R. Genders: Steel and its Thermal Treatment: The Heat Treatment of Carbon Steels.

Fulham Central Public Library, at 8.—A. S. E. Ackermann: Popular Fallacies.

SATURDAY, January 29.

Horniman Museum (Forest Hill), at 3.30.—Miss M. A. Murray: Some Invasions of Ancient Egypt.

SATURDAY, JANUARY 29, 1927.

Trusts and National Progress.

THE nineteenth century was known as the 'steel' age. Attempts to find a word to describe the present age have not succeeded. 'Chemical,' 'wireless,' and 'flying' are adjectives which prejudge the issue of the fierce rivalry between chemists, physicists, biologists, psychologists, engineers to leave an impress on their day and generation. Pending a decision, it is safe to suggest that the present age is an age of 'surprises.' The War itself was a surprise—its outbreak to Great Britain, its result to our enemies; and many of the surprises which have followed that event with bewildering profusion are attributable to the War. We shall find a good example in the history of the 'trustification' of industry. Had anybody predicted before the War that the present year of grace would see the promotion of a great chemical combine—the Imperial Chemical Industries, Ltd.—with a nominal capital of £65,000,000, he would have been advised to consult a mental specialist. In the years preceding the War, the United States, under special legislation, was ruthlessly suppressing its powerful trusts as inimical to the public welfare. Is it possible that the stone which the American builder rejected should become the corner-stone of the British economic temple?

There were a few trusts in Great Britain before the War, together with their by-product in the form of millionaires—a few only, and these, unable to establish a monopoly, provoked no strong public opposition. To tell the truth, these trusts showed no disposition to grind unduly the faces of the poor. An occasional newspaper war regarding the price of soap or sewing-cotton served its immediate purpose of increasing the circulation of the newspaper, and may incidentally have reminded the manufacturer that there is a limit to the exploitation of the consumer. But the public at large showed no great interest in such questions, or indeed in kindred questions vitally affecting the public safety. As to the chemical industries, how many foresaw the importance these industries would assume in the prosecution of the War? It was known that the 'heavy chemical' industries were prosperous, but the dye industry, based on the discovery of an English chemist, had virtually acknowledged defeat. Some eighty per cent. of the dyes used in Great Britain before the War were imported from abroad, mainly from Germany.

"Trusts," says a well-known encyclopædia in the opening words of its article on this subject, "are large business organisations which aim at restricting or eliminating competition" In relation to the conditions, national and international, obtaining to-day, this definition is obviously partial and strabismal. Possibly it is the work of one of those economists whose predictions, as a speaker said at the British Association meeting last year, are generally falsified by events. We are asked to imagine an idyllic scene in which two competing manufacturers producing the same article, one to sell at 2*d*. per lb. and the other at 2¼*d*. per lb., decide to 'combine' and sell their total product at 2¼*d*. per lb. The position which the coal industry, the chemical industry, and other great British industries are facing to-day is more complex. "Amalgamations," says Sir Alfred Mond, the evangelist of the new economic gospel, "mean progress, economy, strength, prosperity." They are the bulwarks of defence for which the whole community has been patiently waiting, "offensive weapons against those enemies at home and abroad who are attacking insistently and insidiously the fortress of the national fortunes."

In cold truth we are entering on an economic war which will lead to the extinction of the less strong and efficient nations. This war will be fought out by large-scale and highly organised units; and the form of organisation ensuring the maximum of financial strength and stability, the minimum of duplication of plant and service, the concentration of the best brains available on the real problems of industry, the most effective methods of promoting scientific research and the application of scientific discoveries, will win the day. Already the amateur company director is beginning to spell out the writing on the wall, and scientific workers are at long last seeing their value appreciated by the industrialist. The question whether, in making our plans for this economic war, we are pursuing the best policy, tactical and strategical, is of direct and vital interest to every citizen.

This question has innumerable aspects, and some of these cannot appropriately be discussed in detail in a scientific journal. Political influences are obviously of the highest importance—not in the narrow sense of the form of government, Tory or Labour, which may happen to be in power at any particular moment. Direct and indirect government aid to scientific research, diplomatic and consular services, factory and patent legislation, monetary system, trade union regulation, health and unemployment insurance, and a hundred other influences are at work, promoting or hindering the progress of industry. Our educational organisation is a powerful influence both in raising the general average of intelligence and in selecting and training those 'captains of industry' whose silent moves on the chequer boards of manufacture and commerce may lead to disaster or victory. Industrial psychology is a new and important science, and 'the human factor' in industry will have to receive increasing attention. But labour difficulties have not caused serious trouble in the *scientific* industries —a good sign and omen.

The loss of the dye industry before the War, to which reference has been made, affords a good illustration of the working of some of these influences It is a twice-told tale reflecting no great credit on our Victorian forbears. Dr. Herbert Levinstein says:

> "If after the Franco-Prussian war *laissez-faire* had not been the policy of the State, a very different position would have resulted in this country. If the State had provided duty-free spirit on terms comparable to those enjoyed abroad; protection for inventions, and prohibition of import of dyes manufactured abroad; information concerning foreign products, and, above all, an assurance of a benevolent interest in the industry; do you think that Perkin and Nicholson would have left?"

The official apology of the British Dyestuffs Corporation harps on the same string and strikes a new note in pointing to the lack of systematic research and of facilities for training organic chemists. Our ancient universities, content in producing educated men of a particular type, adopted an attitude of indifference, or even of scorn, to the public demand for scientific education. The Government, dimly recognising the public need, did a useful service in establishing the Royal College of Science. But Hofmann, one of the most distinguished professors of that college, inspirer of those researches of Perkin which laid the foundation of the dye industry, was attracted back to Berlin, after the death of the Prince Consort: his companions followed him, and took with them much of the expert knowledge of aniline dyes. Ambassador Walter Page, in one of those illuminating letters written during the War to President Woodrow Wilson, which have raised our respect and affection for the United States, referred to some things which the Allies would do in "the war after the War." The Germans, he wrote, had used commercial and financial methods in England, and in Russia in particular, which were unmoral if not immoral—methods which might have been taken out of the book of a decade or so about the Standard Oil Company.

"They 'dumped,' and killed competition by starving out competitors. They conducted systems of commercial espionage, etc. etc. etc. The English were slow to detect these things, and sluggish to move against them. They will be neither slow to see nor sluggish to act for some time after the War. They will try, too, to prevent dependence on Germany for dyestuffs and other monopolised articles."

This prediction has been verified. Forming part of a great combine of the chemical industries, the British dye industry, a key industry as the War has shown, will be able to play a worthy part in "the war after the War."

Adequate finance is not, however, the only advantage which the new trust will offer to the dye industry. Of special interest, fully recognised by the promoters of the trust, is the question whether it will be possible to improve methods and results in scientific research. The record of the constituent companies in this respect is creditable enough, and the work they accomplished during the War earned the gratitude of the nation. But combination must tend towards greater economy and greater efficiency. Industrial research, as Dr. Levinstein has pointed out, can only be successfully conducted by great organisations. The expense of a scientific staff is too great to be borne by the average manufacturing concern of moderate size.

> "There is nothing so unprofitable," he says, "as employing a number of chemists who either have not the knack of discovering things for you, or who discover things for you that you have not got sufficient technical ability to work on a large scale, or for which you have not sufficient discernment to find a market."

The inventive chemist is generally a pure research chemist without knowledge of or interest in large-scale production. Are we not disposed to overlook the high and difficult character of the scientific, technical, and engineering work which transmutes the laboratory product into an article of commerce? For example, the combination of nitrogen and hydrogen under high pressure in the presence of a catalyst to produce ammonia was a reaction of academic interest until Haber pointed out to the Badische Company that the cost aspect would be altered if the ammonia could be separated from the compressed gases without the pressure being released. Even so, the working out of the process was a colossal undertaking, so complicated that Dr. Levinstein suggests that no firm in Great Britain could at the time have adopted the idea. We have good reason to know and to remember how the process enabled Germany to prolong the War by rendering that country independent of supplies of Chile saltpetre; and we have good reason also to be grateful for the enterprise of Messrs. Brunner, Mond and Co., who have overcome the technical difficulties and established at Billingham the synthetic nitrogen industry—an industry which will literally change the face of the earth, making the desert places smile and rejoice. The modern chemist can call spirits from the vasty deep.

> "Why, so can I; or so can any man:
> But will they come, when you do call for them?"

What is the chemist's reply to this searching Shakespearian question? He selects a very inert element in the air and turns it into manna to feed the multitude. In some instances, science is able to supersede natural processes. The synthesis of indigo by the Germans, one of the greatest triumphs of industrial chemistry, the result of prolonged and expensive scientific research, has thrown thousands of acres out of cultivation. Artificial silk has caused the silkworm 'to go out of business.' The men of science who work these miracles derive no stimulus from the lash of competition. By pooling our resources, spiritual and material, we may hope to obtain the best results and to compete on even terms with other highly organised nations.

We come, finally, to an aspect of the question on which Sir Alfred Mond rightly lays stress—the question of national psychology. We are suffering, he says, from the people who are always sitting round with the 'No' complex; people who dedicate their intellects to the congenial task of creating difficulties and objections to every proposed development; people who themselves achieve nothing except to hold up the march of progress of nations and industries. The only real advantage which America has over us, he suggests, is that the Americans welcome new ideas and are always ready to give them a trial. "You want more people with the 'Yes' complex," he says. "There is no room for the 'No' people: they must get out of the way or it will be a serious thing for this country." We have the men, the money, the material. "I am not in the least impressed," Sir Alfred Mond says, "with the technical superiority of any other people in the world." There are no abler chemists or engineers to be found; and our working men are "extraordinarily adaptable, highly skilled, and well trained." No miracle is required, no new dispensation from Heaven, to keep Great Britain in the forefront of industrial nations—only common sense, energy, and the spirit of research.

T. LL. H.

The Greek Conception of Theoretical Geometry.

The Thirteen Books of Euclid's Elements. Translated from the Text of Heiberg, with Introduction and Commentary, by Sir Thomas L Heath. Second edition, revised with additions. Vol. 1: Introduction and Books I., II. Pp. xii + 432. Vol. 2: Books III.-IX. Pp. vi + 436. Vol 3: Books X.-XIII. and Appendix. Pp. vi + 546. (Cambridge: At the University Press, 1926.) 70*s.* net.

THE preface to the first edition of Sir Thomas Heath's translation of Euclid's "Elements" begins with the following quotation from De Morgan: "There never has been, and until we see it we never shall believe that there can be, a system of geometry worthy of the name, which has any material departures (we do not speak of *corrections* or *extensions* or *developments*) from the plan laid down by Euclid." In 1908, when that edition appeared, the movement in favour of a text-book for schools that discarded Euclid's order and proofs was in full vigour, and, in reference to that movement, Sir Thomas Heath contented himself with saying: "It is, perhaps, too early yet to prophesy what will be the ultimate outcome of the new order of things; but it would at least seem possible that history will repeat itself and that, when chaos has again come into geometrical teaching, there will be a return to Euclid more or less complete for the purpose of standardising it once more."

The possibility suggested in 1908 may be asserted in 1927 as a probability, if not indeed a certainty. Among the many text-books that have appeared in recent years—and some of these have many excellent features—there is none that could possibly have induced De Morgan to change one word of the sentence quoted above. The revolt inaugurated by Ramus in the sixteenth century against the Euclidean system and in favour of the admission of many theorems as 'obvious' has its counterpart in recent times, and there are many signs that the inadequacy of the new system is being felt as decidedly now as in the earlier period. But whether there is to be a return to Euclid, more or less complete, or a continuance of the wider liberty prevailing at present, it is very desirable, indeed essential, that all who have charge of the teaching of geometry should make a real study of the development of the science, especially in its early stages, and its reduction to an ordered system in the writings of Euclid. Probably few, if any, desire a return to Euclid *simpliciter*, but, whatever be the attitude to Euclid's "Elements" as a text-book, it is quite impossible to form an adequate appreciation of the influence of mathematics on modern thought without a careful study of the Greek geometry; for such a study there is no better basis than these volumes of Sir Thomas Heath.

It is a tribute to the excellence of the first edition that, while numerous changes have been made in the second, chiefly due to the new knowledge gained in recent researches, these changes are comparatively small; but the revision has been very thorough, and many passages have been rewritten. The paging, however, has been preserved, so that the page-reference to any proposition is the same for both editions. Two new excursuses are appended to the first volume. The first of these is on "Pythagoras and the Pythagoreans," and discusses at greater length certain views that had been dealt with in the notes to Euclid I. 47; the second bears the title "Popular Names for Euclidean Propositions," the names being: *Pons Asinorum, Elefuga, The Theorem of the Bride, The Bride's Chair, Dulcarnon, Francisci Tunica, Goose's Foot* (*Pes anseris*), and *Peacock's Tail* (*Cauda pavonis*). Those to whom any of these names is unknown may be amused by trying to find a proposition that fits it.

Euclid was not the first to write a treatise on geometry, and doubtless many theorems were known and applied before any proof of them was systematically attempted. Unfortunately, the character of the early proofs is to a very considerable extent a matter of guess-work. The very excellence of Euclid's "Elements" swept away such earlier treatises as existed, and such information as we have of them must be extracted from later commentators; even these are chiefly known through Proclus, whose commentary on the first book of Euclid is thus of fundamental importance in the history of mathematics. If the text of Proclus is trustworthy, it is hard to believe that he was an able geometer, but he was a well-trained philosopher, and, we may assume, was familiar with the philosophical principles that lay at the basis of theoretical geometry. Be that as it may, it is on Proclus more than any other single writer that we are dependent for our knowledge of the conditions under which Euclid worked.

In the introductory chapters of vol. 1, Sir Thomas Heath gives a most illuminating discussion of the bearing on Euclid's system of the philosophical conceptions of the period antecedent to the composition of the treatise. Accurate scholarship, wide knowledge, and, of equal importance, calm and restrained judgment, mark the treatment of a subject that has been too often the occasion for rash assertions. A study of these chapters throws a strong light on the difficulties that are involved in the passage from 'practical geometry' to geometry as a science, and proves the practical sagacity as well as the mathematical ability of the writer of the "Elements." Euclid was no mere redactor; it may be, and probably is, the case that now and again he had not the courage to discard older statements, but it demanded genius of a high order to reduce the loose and vague generalities of earlier treatises to a system that is at once comprehensive and logically compact.

It is impossible to discuss these volumes in detail, but it may be said that to almost every proposition interesting notes are appended that, in their totality, form an excellent introduction to the history of geometry; the numerous references, if followed up, would form a fascinating study and do much to make the geometry lessons more interesting to pupil and teacher alike. The inclusion of Euclid's arithmetical books is specially welcome, and one may express the hope that the tenth and thirteenth books may now become something more than names to all who are interested in geometry; nowhere is Euclid's genius better seen than in these books. But the most ardent adherent of Euclid would scarcely object to the simplification that is introduced by modern symbolism in an elementary treatment of the constructions in Book XIII.

It is almost impossible to praise too highly the selection from the overwhelming material with which Sir Thomas Heath had to deal or the luminous exposition of many difficult topics; his mastery of English is nowhere better shown than in the translation of the text, where the flavour of the original is never lost, and yet due respect is paid to the English idiom. The only *caveat* I would make is that, at times, there is a tendency to read too much into the Greek texts. For example, I find it impossible to assent to the statement (vol. 1, p. 220) that Playfair's postulate "is distinctly stated in Proclus' note to Eucl. I. 31." It is one thing to *prove* that, with Euclid's postulate, there is only one parallel through a given point to a given straight line (and this seems to me to be at most what Proclus does); it is quite a different thing to reverse the process, and this is the essence of Playfair's procedure. Playfair, of course, does not claim the credit of the axiom; he says that the axiom "has been assumed by others, particularly by Ludlam." Who are the others? I do not know, but Playfair's discussion seems to show that he at least did not see it in Proclus. There are other cases in which I think too much is read into the older treatises, but, after all, these considerations are largely matter of opinion, and the debt which mathematicians owe to Sir Thomas Heath is too great to justify more than a passing reference.

GEORGE A. GIBSON.

Festschrift Carl Schröter.

Veröffentlichungen des Geobotanischen Institutes Rübel in Zürich, Heft 3. Festschrift Carl Schröter. Gewidmet von seinen Freunden, Schülern und Kollegen. Im Auftrag des Schröter-Jubiläum-Komitee redigiert von H. Brockmann-Jerosch. Pp. viii + 811 + 28 Tafeln. (Zürich: Rascher und Co., 1925.) 30 francs.

ON December 19, 1925, Carl Schröter, still "Professor der Botanik an der Eidgenössischen Technischen Hochschule in Zürich," celebrated his seventieth birthday. A *Festschrift* of 811 pages, containing an account of Schroter's life and work by Rübel, a former student and present colleague, and forty-nine original articles by botanists of some thirteen nationalities, was published in honour of the occasion.

The influence of Carl Schröter has been great, not only on the institution in which he was first a student and afterwards professor for forty-two years, but also on the development of Swiss botany in general. Since 1882 his chief interest has been ecological plant geography, a study to which he was attracted by a perusal of Christ's "Pflanzenleben der Schweiz," and Kerner's "Pflanzenleben." His influence on the subject to which he has devoted his life can be compared with that of Schimper and Warming. He has been an indefatigable investigator, a mere list of his publications occupying some thirteen pages of the *Festschrift*. His published researches, independent or in collaboration, include many important studies on the vegetation of Swiss grasslands, moorlands, and lakes, while his extensive knowledge of alpine plants is summed up in his well-known "Pflanzenleben der Alpen," now in its second edition.

Schroter's influence, however, has been due even more to his personality as a man and a teacher than to his writings. Above all, he is intensely human. Tansley, in his article in the *Festschrift*, refers to "the distinguished and beloved founder of the Zürich school, who has contributed so much by example and personality to international understanding and co-operation." The secret of his success in this respect may be summed up in the words of Rübel, "Für ihn liegt der Zweck des Lebens im Geben." In the lecture room, laboratory, and not least in the field, Schröter always gave of his best to his students, and in return received from them unswerving loyalty and devotion. Thanks to Schröter's inspiring leadership, the Zürich school of plant geography (or that branch of it known as plant sociology) is now one of the most active centres in the world for the study of natural vegetation.

Schröter's keen love of Nature led him to take a most active part in the Nature Reserve movement. He was one of the founders of the magnificent Swiss National Park, on which he contributed an article to NATURE (vol. 112, p. 478, 1923), and he selected it in April of last year as the subject of his Hooker lecture to the Linnean Society of London. His reverence for Nature was brought home to me some years ago as he and I stood together near the Kleine Scheidegg. Glancing from the Jungfrau and the Mönch, bathed in sunshine, to the modern hotels in the foreground, Schröter exclaimed with intense feeling, "It is a desecration."

In the pursuit of his ecological studies Schröter has travelled widely. From the first he made field excursions a special feature of his botanical teaching. Zürich students are fortunate in having the Alps, "The Playground of Europe," at their very doors. But sometimes more distant excursions, for example, to Corsica or Algeria, are organised. In this respect British botanical schools have hitherto been less enterprising than the Swiss and some American schools. Schröter himself has visited many parts of Europe, the Sahara, the Canary Islands, the United States, and in 1898–99 travelled round the world. Even now, in his seventy-first year, he is absent on a year's journey to South Africa, India, and the Far East.

It is impossible within the limits of a review to do more than indicate something of the scope of a few of the articles contributed to the *Festschrift* by botanists of many lands. The articles are grouped into eight sections according to subjects.

In the first section are fifteen papers dealing with Alpine and Arctic vegetation. Rübel (Zürich) shows that many of the plants of high Alpine meadows hibernate under deep snow in a green condition. Evergreen meadows are not confined to the lowlands. Du Rietz' (Upsala) work on the altitudinal ranges of plants of northern Lapland appears to suggest that edaphically indifferent common species may be important as indicators of climate. Rikli (Zürich) resolves the Alpine-Arctic flora into elements derived from various distributional centres, and discusses probable routes of migration. Flahault (Montpellier) gives a general account of wind and snow as ecological factors. He instances cases of young conifers buried under winter snow being killed, not by cold, but by asphyxiation brought about by overlying layers of snow and ice.

The second section (nine papers) is devoted to extra-Alpine vegetation. Tanfiljef (Odessa) describes the natural alluvial meadows (Auen) of Russia. Much of the grassland of western Europe is at best only semi-natural, but true natural meadows occur in river valleys in east Europe and Siberia. The treelessness of the valley meadows of northern Russia is attributed to the prolonged waterlogging of the soil, and to the velocity of the ice-covered rivers, when the melting snow floods the valleys in springtime. Morton (Vienna) discusses the flora of caves from the physiological viewpoint. Blue-green and green algæ in particular are extremely tolerant of shade, some retaining their chlorophyll after years of cultivation in darkness. "The Structure of Woodlands" by Salisbury (London) deals with the stratification of woodland vegetation in relation to gradients of atmospheric and soil conditions. Four types of undergrowth species are distinguished, according to the time of development and duration of the assimilating organs. MacDougal (Arizona) describes the rapid changes in vegetation of an area adjacent to the Gulf of California, consequent on draining and increasing salinity. Podpěra (Brünn), in a paper on the origin of present-day European forests, groups Eurasian forests into Tertiary forests, Relict forests, the Eurasian Taiga and the dwarf forests of high mountains and Tundra. Miocene aridity and Pleistocene glaciation have profoundly modified the original Tertiary forests. Tansley (Cambridge) analyses the vegetation of the English Chalk. He emphasises the important point, ignored in the early days of ecology, that vegetation cannot be understood unless it is investigated from the developmental point of view as well as from that of habitat factors.

The third section of the book contains four papers by Pavillard (Montpellier), Chodat (Geneva), and others, on phyto-plankton.

The fourth part has five papers on phyto-palæontology and historical plant geography. Neuweiler (Zürich), from evidence afforded by fossil woods, concludes that from Palæolithic to Roman times the Swiss forests north of the Alps contained 82·3 per cent. of deciduous trees, and only 17·7 per cent. of conifers. He criticises, quite justly, statistics based on the modern pollen analyses of peat. Herzog (Munich) finds, in a study of the geographical relations of the mosses of south Brazil, strong support for the hypothesis of Wegener and others, that the continents of Africa and South America were formerly continuous.

Section 5, on systematic botany and genetics, contains one short paper by de Vries (Holland) on the quest for the origin of species, and five other papers.

Under the heading "Soziologische Begriffe" (Section 6) are four papers, two of which deal with the struggle for existence amongst plants. Cajander (Helsingfors) adduces convincing evidence that the limits of natural distributional ranges of species. The sharpness of the boundaries of particular plant communities, as well as the definite structure of these communities, are largely determined, in the last resort, not by climate or soil, but by the mutual struggle for existence. Yapp (Birmingham) analyses the probable inter-relationships of plants in vegetation, and introduces the new concept of 'priority' as distinct from competition. Priority amongst plants is the passive interception of supplies of a necessity by an organism which is more favourably situated than another.

Section 7 on anatomy and physiology contains one paper by Jaccard (Zürich) on the weeping ash, and the final part (Section 8), five papers on economic botany.

From this brief résumé it will be seen that most of the papers have a direct or indirect bearing on the comprehensive subject of plant geography. Many reach a high level of importance, and not a few are concerned more with general principles than with details. The volume distinctly enriches the literature of plant geography. It has been well edited by Brockmann-Jerosch on behalf of the Schröter-Jubiläum-Komitee, and is well printed and illustrated. The *Festschrift* forms a sincere and fitting tribute to a singularly winning personality.

R. H. YAPP.

The New Wireless Technique.

The Theory and Practice of Radio Frequency Measurements: a Handbook for the Laboratory and a Textbook for Advanced Students. By E. B. Moullin. (Griffin's Scientific Textbooks.) Pp. xi + 278. (London: Charles Griffin and Co., Ltd., 1926.) 25*s.* net.

IT is difficult for a wireless worker of to-day, who has been trained along modern lines, to realise how much precision has been introduced into his subject by the development of the thermionic valve. Important radio measurements were made in pre-War days, but in every case strong signals had to be used. The difficulties were largely due to the relative insensitivity of the instruments available for the measurement of high-frequency currents and potentials. But this, of course, did not prevent the pioneers of those days from making the very best use of the instruments at their disposal, and more than twenty years ago Duddell and Taylor, in a classical series of experiments, laid the foundations of the subject of signal measurement by studying the falling-off of signal intensity with increase of distance from a radio transmitter. In these experiments the high-frequency currents produced in a receiving antenna were measured directly with a Duddell thermogalvanometer. Although audible signals were detectable at much greater distances, quantitative observations were possible only up to a distance of 80 miles. In signal strength measurements over long distances, subjective methods involving audibility comparisons had to be used which were not very trustworthy.

The development of the thermionic valve has changed all this. It has supplied us with transmitters of electric waves which are remarkably constant in amplitude and frequency. It has made possible the building of stable amplifiers by means of which small oscillatory currents and potentials may be magnified to sufficient volume to affect our alternating current measuring instruments. Finally, in the tube itself we have a high-frequency voltmeter of precision.

The absence of a comprehensive account of the methods and devices now at the disposal of the wireless engineer and research worker has been felt for some years, and we are grateful to Mr. Moullin for undertaking the task of writing one. His work cannot have been easy. The setting-up of a wireless set, to receive signals, is easy, as every schoolboy knows, but once the word 'measurement' is introduced in connexion with high-frequency phenomena, difficulties begin to appear. None of these difficulties has been shirked by Mr. Moullin. Throughout his volume the physical principles are clearly interpreted, and every page bears witness to his wide experience in dealing with students' difficulties. As an example of this we may quote the practical details and advice he gives concerning the use of low-power valve generators for laboratory experiments. The instructions he gives for designing, setting-up, and adjusting for maximum output a valve generator to meet given requirements could scarcely have been improved.

The older books on wireless telegraphy have dealt with measurements of high-frequency resistance, capacity, and inductance, but Mr. Moullin has much to say that is new. In the sections on the measurement of frequency and of signal intensity all the newer methods are given, including an account of Mr. Dye's very important work on the multi-vibrateur. In view of the importance of the use of quartz crystals as frequency controllers in a wireless spectrum already crowded, it is unfortunate that the work of the same author on this subject was published too late to be included.

There is no doubt that Mr. Moullin's book will be widely read by wireless engineers, but we must very reluctantly point out that the price of the volume is too high for it to be used as a text-book in university classes and thus assist in missionary work among the younger generation of physicists. E. V. A.

Our Bookshelf.

Handbuch der biologischen Arbeitsmethoden. Herausgegeben von Prof. Dr. Emil Abderhalden. Lieferung 204. Abt. 9: *Methoden zur Erforschung der Leistungen des tierischen Organismus,* Teil 1, Hälfte 2, Heft 2. Spezielle Methoden: *Tierhaltung und Tierzüchtung.* Pp. 215 + 484. (Berlin und Wien: Urban und Schwarzenberg, 1926.) 12·30 gold marks.

NOTICES of successive fascicules of this comprehensive work edited by Prof. Abderhalden have frequently appeared in our columns. The present instalment is concerned with the biology of insects and the technique of breeding and rearing those animals for purposes of scientific observation. Several groups have already been dealt with in Lieferung 182, and in the part before us most of the larger orders are considered.

Dr. C. Börner discusses the Homoptera with special reference to the aphides. His contribution includes a useful list of numerous members of the latter group in different parts of the world, with their known primary and secondary hosts. This is followed by a section dealing with the transmission of mosaic and other plant diseases through the agency of various Homoptera. The Lepidoptera are dealt with by Dr. E. Fischer, whose account is divided into two parts. The first is concerned with methods of collecting, and is followed by a larger section on the technique of rearing, including pairing, counteracting disease, and conducting experiments under varying conditions of heat and cold.

Dr. F. Heikertinger contributes the chapters on Neuroptera, Trichoptera, Mecoptera, Coleoptera, and Diptera. The accounts of the last two orders mentioned are in considerable detail, each family being considered separately. The concluding part is on Hymenoptera, by Dr. J. Fahringer. This is more curtailed than the preceding sections, and we think might have been expanded to advantage considering the specialisation of technique often required, especially with regard to the parasitic members of the order. A. D. I.

Chemistry and Recent Progress in Medicine. By Prof. Julius Stieglitz. (The Johns Hopkins University School of Medicine, The Charles E. Dohme Memorial Lectureship, Second Course, 1924.) Pp. viii + 62. (Baltimore, Md.: Williams and Wilkins Co.; London: Baillière, Tindall and Cox, 1926.) 7*s*. net.

THE subject matter of this little volume is indicated by its title and does not follow any very novel path. The work referred to is mainly trans-Atlantic and its presentation suffers somewhat from the fact that more than a year has elapsed between the delivery of the lectures and their publication. About one-third of the book is devoted to the subject of oxidation, in which the author develops the theory that oxidation is a loss of one or more electrons, and reduction, correspondingly, their gain, by atoms or ions of the molecules taking part in the reaction; in this connexion reference is made to glutathione.

Among other applications of chemical or physico-chemical principles to medical problems to which reference is made, are the conditions necessary for the deposition of calcium phosphate in bone and the study of blood as a physico-chemical system. In the earlier part of the book the author reviews the progress made in preparing synthetic drugs for therapeutic purposes and in isolating the active principles of the internal secretory glands of the body. Among the substances mentioned were noticed ethylene as an anæsthetic, certain of the arsenical derivatives and dyes used clinically, the secretions of the pancreas, pituitary gland, and ovary, and the isolation of purified principles from antibacterial sera.

Heredity. By Prof. A. Franklin Shull. (McGraw-Hill Publications in the Zoological Sciences.) Pp. xi + 287. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1926.) 15*s*. net.

THE author, who is professor of zoology in the University of Michigan, states in his preface that this volume represents a course of lectures delivered for several years to large classes of students who were admitted "without prerequisite." Doubtless for this reason the presentation of the subject matter is more or less popular, and in consequence somewhat dogmatic and superficial. Besides the phenomena of heredity proper, it deals with such topics as problems of population, immigration, and eugenics. Though by no means a poor book, it is rather mediocre and lacking in distinction. Probably it is better adapted to the audience for which it was planned than to an English one, but if it should help to stimulate interest in such matters it will have served a good purpose.

Letters to the Editor.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Wireless Communication and Terrestrial Magnetism.

Dr. Chree's letter in Nature of Jan. 15 alludes to the names which might be associated with that upper portion of the atmosphere the aid of which is so often invoked to account for many of the facts of wireless telegraphy. May I explain why I happened to choose the name "Heaviside layer" some sixteen years ago?

In the spring of 1902 I was writing from time to time on wireless telegraphy in the pages of the *Electrician*, and one day Mr. Tremlett Carter, the editor, showed me a letter from Mr. Oliver Heaviside which, while discussing other things, asked if the recent success of Mr. Marconi in telegraphing from Cornwall to Newfoundland might not be due to the presence of a permanently conducting upper layer in the atmosphere. I believe this letter was shown to various friends of the editor, but I think it was not published. The substance of the suggestion was repeated by Heaviside in his article in the new edition of the "Encyclopædia Britannica" which appeared in America and in England in 1902. The suggestion was gradually approved during the years that followed; and about 1910 I used the convenient name 'Heaviside layer' in a paper, to indicate the portion of the atmosphere that functions so usefully for the purposes of wireless telegraphy.

The existence of a conducting stratum in the atmosphere, and the probable connexion of the stratum with the aurora, must have been surmised by every observer of electric discharge in rarefied gases even before the date of Cavendish; and as Dr. Chree points out, Balfour Stewart suggested that a conducting layer might have to do with certain variations of the magnetic elements. Schuster, I believe, first gave definiteness and substance to this suggestion. Later, G. F. Fitzgerald calculated the period of electric oscillation of the earth supposed surrounded by a sharply defined conducting layer in the upper atmosphere, thus for the first time introducing the conception of a relationship between electric waves and an upper layer. But, so far as I know, there is as yet no evidence that the auroral layer is the same as the Balfour Stewart or Schuster layer, or that this is the same as the Fitzgerald layer, or that any of them are the same as the physically present layer called for convenience the Heaviside layer. Therefore it seems to me that to call the wireless layer by the name of Cavendish or Balfour Stewart or Schuster, or even Fitzgerald, would assume too much. Why not let well alone until there is proof that the Heaviside layer is the same thing as one or other of the hypothetical layers?

May I take this opportunity of referring to another matter. I wish to urge that full advantage should be taken of the solar eclipse next June for learning more about the Heaviside layer. The map given in Dr. Lockyer's excellent article in Nature of Jan. 15, leads one to suggest that a wireless transmitting station near London and another in the north of Scotland should be devoted to transmitting signals continually throughout the eclipse period, so that receiving stations scattered about Great Britain might observe the intensity of signals which have crossed the path of the moon's shadow. Galvanometric measurements of a continuous stream of waves from the transmitters would be the ideal type of observation; but aural observations of the intensity of a code signal, if the time of each observation were accurately registered, would also be valuable.

In the latter case the method devised by the British Association Committee for use in 1914 may be recalled. Each transmitting station—one in Russia, one in France, and one in Ireland—was assigned a sequence of Morse letters for continuous transmission, the sequence of letters being such that no succession was ever repeated. A chronographic record of the transmitted sequence was to be made at each transmitting station, and observers had no other task than to write down the letters heard, heavily when the signals were strong, lightly when they were weak.

It was hoped that analysis and comparison of the records would show the effect of the shadow cone on waves passing through it; but the War came, and the organisation which had been built up for making observations throughout Europe immediately collapsed. Would it be possible, on the occasion now approaching, to arrange similar wide-spread European observations of signals proceeding from a special station in the north of Scotland? Indeed, if short waves were used, observations at a number of selected distant points of the globe would probably yield highly interesting results.

Buckingham Gate, S.W.1, Jan. 17.

The Beginning of Agriculture.

May I be allowed to make a few remarks on some of the points to which reference is made in Prof. Elliot Smith's letter on "The Beginning of Agriculture" in Nature of Jan. 15, p. 81?

The observation that "The statement that barley was the staple article of diet in Egypt from the earliest pre-dynastic period has passed without any notice whatever during the last fifteen years," would scarcely be made by any one acquainted with ancient cereals. That barley was an important cereal in Egypt in pre-dynastic and dynastic times is quite certain, for samples of this grain from these periods are well known. Its importance, however, was shared with Emmer wheat (*T. dicoccum*), and from the frequent 'finds' of the latter, often mixed with barley, I think it is probable that both were of equal importance for a long period, after which other races of wheat probably derived from Emmer took foremost place in the diet of ancient Egyptian and Babylonian populations.

The opinion expressed in the letter of Prof. Netolitzky that wheat was not eaten by the pre-dynastic people of Egypt, if based, as it appears to be, on the results of his examination of the material taken from the intestinal tracts of the Naga-ed-Dêr specimens, is of little value. The microscopic analysis of Prof. Netolitzky revealed the presence of barley husks in this material, and the discovery was confirmed by Frau Gherasim. Wheat husks were not found, and their absence Frau Gherasim asserts "definitely establishes the fact that pre-dynastic people did not eat wheat." Such a conclusion, based on the evidence given, is, to say the least, unwarranted. Two explanations may be given of the absence of wheat husks in the intestinal material examined, namely, (1) the human beings concerned had not recently eaten wheat; (2) in barley the husks (glumes) are closely adherent to the grains, and portions of them are consequently consumed with them, whereas in wheat the husks or glumes are free from the grains and must be removed before the latter can be used as food. That the husks were removed from Emmer wheat before the grains were used in ancient Egypt is amply proved by the frequent discovery of dehusked grains and the separate empty husks.

In regard to the antiquity of Emmer in Egypt, the following samples have passed through my hands: (1) From an undisturbed site of Badarian people (3500 B.C. or 5500 B.C., Petrie), sent by Mr. Guy Brunton; (2) a sample sent by Miss Caton Thompson obtained from a settlement of the second prehistoric period, near Qau; (3) from straw-lined pits found in the Fayum area by Miss Caton Thompson and dated by Sir Flinders Petrie at least 10,000 B.C. With these Emmers, barley was also found, and in the excavations which revealed sample (3) were also found the naked grains of a race of wheat which cannot be determined with certainty.

During the last week I examined a sample of naked grains of wheat discovered by Prof. Langdon in a vase on the site of an old Sumerian house in Mesopotamia and estimated by him to date from a period at least 3500 B.C. These, in my opinion, belong to a variety of Rivet wheat (*T. turgidum*), a race showing affinities with Emmer and doubtless derived from it. This is the first authentic sample of Rivet wheat which I have seen from ancient Babylonia or Egypt.

The present distribution of wild barley and wild Emmer suggests that even in the beginning of agriculture, primitive man would have the choice of both, and I doubt if ever there was a time when barley only or Emmer alone was the cultivated cereal. All the trustworthy evidence we possess shows that both barley and wheat were grown by the earliest agriculturists of whom we have any definite knowledge, and it appears to me likely that by the time agriculture had become sufficiently advanced to provide for even a comparatively small population, the merits of both these cereals would have been well established.

Into the question whether civilisation originated in Egypt or Babylonia I am not competent to enter, but I may point out that unless climatic conditions have undergone considerable changes in these regions, it may safely be concluded that Emmer wheat and possibly barley were taken there from Syria and Palestine, where they occur in a wild state.

The origin of the all-important bread wheat (*T. vulgare*), which has almost entirely supplanted Emmer and barley as human food, remains obscure; so far as trustworthy evidence goes, it was unknown to the ancient Egyptians and appears to have been a discovery of agriculturists accustomed to a cooler and more northerly climate.

In conclusion, I should like to take the opportunity to urge that small samples, or as much as can be spared, of all ancient cereals, as well as other crops and their associated weeds, discovered by archæologists, should be sent to one central museum—Kew, the British Museum, or the University, Reading, where we have a collection of some 2000 species, races, and varieties of wheat grown annually—where they would be easily accessible for study by experts and their nature more accurately determined than is possible at present, scattered as they are in large and small museums throughout Europe. In the past the naming of ancient cereals, and the wheats in particular, has been appallingly inaccurate, and it is not an exaggeration to say that three-fourths of the published statements about their botanical nature are worthless and misleading, many of them having been made by persons who have had no knowledge of more than one race of wheat, and only recognised wheat grains as distinct from those of barley or oat.

JOHN PERCIVAL.

The University, Reading.

PROF. ELLIOT SMITH has done good service in publishing Prof. Netolitzky's letter in NATURE of Jan. 15, for many must have been puzzled by the discrepancy between the statements made in 1911, and have not had the advantage of the private information with which Elliot Smith very kindly provided me. Frau Hedwig Gherasim's paper has definitely established that barley, and not wheat, was the food eaten at their last meals by the pre-dynastic people of Naga-ed-Dêr, the contents of whose stomachs had been sent to her for examination. To say, however, that this discovery "definitely establishes the fact that the pre-dynastic people did not eat wheat," is more than the facts available warrant.

That barley was used, and presumably cultivated, by the pre-dynastic folk of Naga-ed-Dêr at an early period is quite clear, though precisely how early must remain undetermined until there appears the full report of the excavation of Cemetery 7000, with details of the grave contents. As this was explored in 1901 this publication is long overdue. It has generally been thought that wild barley, *Hordeum spontaneum*, did not grow in Egypt, and no actual occurrence of this plant has been reported. I am indebted, however, to my friend Dr. O. Stapf for the information that during the closing decade of the nineteenth century it was reported from two sites in Tripoli. It is probable, therefore, that at an earlier date it grew also in the north of Egypt. I should be glad, however, to learn the evidence on which Elliot Smith bases his statement that barley is found wild in the regions to the south and east of Egypt.

We can well believe, therefore, that wild barley was brought under cultivation by people living on the banks of the Nile or at the edge of the Delta. Whether they were the only people thus to cultivate wild barley, still more the first to do so, must remain for the present a matter of uncertainty.

Evidence of the occurrence of wheat before the time of King Sahure has been accumulating of late years. In the tomb of Zer, the third king of the first dynasty, Petrie found a carving in wood of an ear, which was at the time described as of 'bearded barley.' It is now accepted by all grain experts as being an excellent representation of an ear of Emmer (*T. dicoccum*). But wheat was known, too, in pre-dynastic times. It is true that the grain found by Legrain and Lampre with a contracted burial between Kawamil and Silsileh, and claimed by them to be Emmer, has been declared by Schultz to be barley, but in the winter of 1912–13 Prof. Peet found at Abydos a range of large pots which had been used for drying grain, and he pronounced them to be undoubtedly of pre-dynastic date. In these were small caked masses of carbonised grain. Some of these grains were examined by Prof. Harvey Gibson, who found them to be wheat (*T. vulgare*). Near by a similar series of pots were found, but containing no grain; these, however, held sherds of decorated pottery belonging to the Middle Pre-dynastic Period.

One may, perhaps, question the identification of this grain as *T. vulgare*. All the grains from Dynastic Egypt so far found have been Emmer, or members of the *dicoccum* group. So far as we know, *T. vulgare* first made its appearance in Egypt in Roman times. It is by no means easy for one who is not a grain specialist to distinguish between *T. vulgare* and *T. dicoccum* in the carbonised state, but Prof. Harvey Gibson is too good a botanist to have mistaken barley for wheat. It is very desirable, however, that this carbonised sample should be submitted to grain experts for determination.

It would appear, then, that during the Middle Pre-dynastic Period, wheat of some kind, almost certainly *T. dicoccum*, was cultivated at Abydos. Yet no one has claimed wheat as native to Egypt. The distribution of wild Emmer, *T. dicoccoides*, is fairly well established; it ranges from Mount Hermon in Syria to the mountains of Moab. A single plant was found by Strauss in the Zagros mountains between Bagdad and Kermanshah. It would seem, therefore, that wheat and the practice of cultivating it must have been introduced from Asia. May not the cultivation of barley have been similarly introduced, for wild barley has a wider distribution in Asia than in Africa?

I have not yet seen Prof. Breasted's new book, but the passage quoted by Elliot Smith is rather surprising. The tablets he refers to are evidently the Nippur tablets and the Weld-Blundell prism. When publishing the latter, Langdon deduced from it that the date of the first dynasty of Ur was about 4000 B.C., though at the last moment in the preface he reduced this by fifty-six years. If from the same source Prof. Breasted deduces that the date of this dynasty is about 2900 B.C., it is clear that these tablets do not determine the maximum age of the earliest written documents with precision. The difference of more than a thousand years is not negligible.

It is quite likely that the second layer at Susa is contemporary with the first dynasty of Ur. The lowest layer, which contained the painted pottery, was succeeded by another layer containing a different type of ware, and this again by a sterile layer, 1 to 2 metres in thickness, before the layer known as Susa II. was deposited. How long it would take for such a thickness of soil to accumulate on an unoccupied hillock it is impossible to compute, but it is clear that the people of Susa I., who were cultivators of grain, lived very long before the first dynasty of Ur.

One sentence in Elliot Smith's letter has somewhat surprised me: "We know that people lived in Egypt at this time, many centuries before the metal copper was known." It is usually conceded that copper objects occur, rarely it is true, in the very earliest predynastic graves; moreover, Brunton has told us that in graves of the Badarian culture, which are earlier still, he found beads made of narrow copper ribbon and a stout copper pin or borer.

I should like to explain that the reason why the facts adduced by Elliot Smith relating to the early use of barley were not mentioned in recent discussions at meetings of the British Association and at the Royal Anthropological Institute was not that they were unknown to many of those present, but that both discussions were confined to the early cultivation of wheat in Egypt, and the question of barley did not arise. I trust, however, that these few lines, giving items of information apparently not very well known, may help to remove some of the widespread misunderstanding of which Elliot Smith quite rightly complains. I hope to deal with the question more fully at the Royal Anthropological Institute next week.

HAROLD J. E. PEAKE.

Westbrook House,
Newbury, Jan. 17.

Biological Fact and Theory.

ON returning from a holiday, my attention has been directed to an attack upon my book "The Physiology of the Continuity of Life," which appeared in NATURE on Dec. 25.

Fortunately an author is not expected to defend himself from criticism, just or unjust, but there is one point in the article which requires attention. The reviewer quotes the statement, "The F_2 shows all gradations from bar-eye to normal eye," and calls upon me to withdraw it. The words occurred as one of the following sentences:

"There are many examples of failure to show the clear-cut differentiation expected in the F_2 generation: Morgan cites the case of the cross between the normal and bar-eyed *Drosophila*. The F_1 generation is intermediate. The F_2 generation shows all gradations from bar-eye to normal eye. Here the segregation does not seem to be complete."

Morgan's words in his "Physical Basis of Heredity," page 31, are: "A mutant eye shape of *Drosophila*, called 'bar' (Fig. 7, *a*), has an intermediate hybrid type (Fig. 7, *b*). The F_2 group may be represented (Fig. 8) in the following scheme:

"Fig. 8.—Relation of bar-eye to normal eye, as shown by the F_2 classes.

In this case the hybrid, intermediate type overlaps the bar type, so that in F_2 these two latter types give a nearly continuous class. At the other end of the F_2 series the round-eyed normal (or wild) type can be distinguished without difficulty from either of the other classes."

I think that my interpretation is justified.

D. NOËL PATON.

University of Glasgow,
Jan. 7.

PROF. PATON's letter is another instance of what I complained of in my review—failure to grasp the fundamentals of genetics before proceeding to attack and criticise its conclusions.

What are the facts about bar-eye as revealed by Prof. Paton's quotation from Morgan? They are: (1) That bar is a partial dominant; (2) that the variability of the heterozygote is greater than that of either homozygote; (3) that the heterozygote's eye-type overlaps that of the dominant; (4) but that it does *not* overlap that of the recessive (wild-type or round eye).

Three further important points not quoted by Prof. Paton are as follows: (5) In F_2 the frequency curve for facet-number (eye-size) is definitely trimodal. There is a discontinuity between the round-eye mode and the rest; but the "nearly continuous class" comprising bar and heterozygote types shows two well-defined modes. (6) The overlap only occurs in the females. This, however, does not mean that the males show segregation, the females not, but is of course due to the fact that no heterozygous males can exist, since Bar is sex-linked (the frequency curve for males alone is therefore bimodal, while that for females alone remains trimodal). (7) We can therefore, as regards overlap, consider only females. But if *any* female from the "nearly continuous class" be taken and crossed with a wild-type (round-eyed) male, one of two results will invariably be seen in the female offspring: either (*a*) they will all be of heterozygous type, with a unimodal frequency curve; or (*b*) they will be half round-eyed and half of heterozygous type, *with no overlap*. Further (*c*), if enough individuals be tested, the ratio of those giving result (*a*) to those giving result (*b*) will approximate 1 : 2.

This can only be explained if the female parents are either of constitution BB or Bb, and that therefore segregation did occur in the germ cells of F_1, as well as in their own germ cells.

Even apart from these additional points, however, the quotation from Morgan definitely shows that segregation exists. For F_1 was all of the heterozygous type, not overlapping with the recessive round eye; and yet in F_2 this recessive wild-type eye was recovered pure, and without overlap!

It should, however, be strongly emphasised that this question of phenotypic overlap has of itself nothing to do with the question of segregation; and this is the graver error into which Prof. Paton appears to have fallen. Segregation—I also quote from

Morgan ("Mechanism of Mendelian Heredity," p. 1)—consists in this, that "the units contributed by each parent separate in the germ-cells of the offspring without having had any influence on each other." The *expression* of any unit in phenotypic characters will of course (again an elementary fact) vary with (*a*) environmental factors; (*b*) the presence or absence of other genetic factors affecting the same character (*i.e.* multiple or modifying factors). The overlap of the heterozygote type with that of one homozygote (which was of course complete in Mendel's original experiments) has *no bearing* on the question of segregation; nor indeed does its overlap with both homozygotes. In such cases, as Mendel showed sixty years ago, breeding tests must be used to discover the constitution of the organisms. For example, in Mendel's tall × dwarf cross there is considerable height-variation of the tall F_2 class (due to environment); but breeding-tests to F_3 (or back-crosses as in my point (7)) show at once that all the tall individuals are either pure talls (TT) or heterozygotes (Tt); some TT's will be taller, others shorter, than the average Tt, and vice versa. The same procedure will prove segregation even when the heterozygote phenotypically overlaps both homozygotes.

I must apologise for going into such elementary facts in the columns of NATURE; but I can only repeat what I said in my review, that the course of biological progress is impeded when distinguished men in positions of authority attack whole disciplines of biology without having understood their data and principles sufficiently well to avoid elementary mistakes.

It may, in conclusion, be mentioned (what again Prof. Paton appears not to be aware of) that in the last few years Zeleny and his pupils have shown, by using purified inbred stock under well-standardised environmental conditions, that the high variability of bar-eye and its heterozygote depends partly on temperature during a 'critical period' of development, partly on specific modifying genes. The pure stock under standard conditions loses the large phenotypic variability described by Morgan, just as a chemical substance ceases to behave irregularly when purified and when experimental procedure is improved.

In this purified stock at 25° C., the mean facet-number (which is directly proportional to eye-size) for females of the classes in question is as follows (Morgan, 1925, "Bibliographica Genetica," vol. 2, 31-32):

Homozygous bar (pure stock or extracted in F_2)	68
Homozygous round-eye (pure wild-type or extracted)	779
Heterozygous bar (F_1 or F_2)	358

It is obvious to my mind that Mendelian theory is far from complete. We know, *e.g.*, very little about the way genes act during development to influence phenotypic characters, and still less about the causes of mutation. But progress will be achieved by building on the ample foundation already obtained by tens of thousands of breeding-tests, not by going elsewhere to erect a superstructure without adequate foundations.

J. S. HUXLEY.

King's College,
Strand, W.C.2.

IN NATURE of Dec. 25, there appears a long review of Prof. Noël Paton's book, "The Physiology of the Continuity of Life," by Prof. Julian Huxley, who criticises the book severely because its author attacks from the point of view of the physiologist the whole edifice of the theory of genes or factors in heredity. I do not propose to intervene in order to support Prof. Paton, who is perfectly capable of defending himself, but Prof. Huxley has seen fit to attack the work of Tornier and to blame the author, and incidentally myself, for holding that it has any bearing on the question of heredity. It was I who gave to Prof. Huxley the references to Tornier's work, and I hold that this work is the most important, and indeed the only work on the causes of mutations which has yet appeared, and that it is worth all the factorial analyses put together. As this work is little known to readers of NATURE, may I briefly summarise its principal features?

Tornier investigated the conditions under which 'fancy races' of goldfish were bred in China, which is the original home of the species. He found that there was nothing recondite in the methods of these breeders; the fish were exposed to insanitary conditions and deposited spawn in these circumstances. The greater part of the eggs died. What survived gave rise to fish of varying degrees of abnormality, and *when these fish were bred these abnormalities were transmitted in some degree to their offspring*. By selection, a reasonably 'pure' 'fancy' could be produced in a few generations.

Tornier analysed the physiological causes of the development of these abnormalities, and showed that they could be reduced to a weakening of the developmental energy of the germ at a critical period of development, and that this weakening was transmitted to posterity and produced in each generation the same results. He imitated as nearly as possible the Chinese breeders' methods with the eggs of Amphibia and got similar abnormalities. He does not give details of experiments on breeding, but he expressly states that all these abnormalities are inherited. Anyone who asserts that Tornier's experiments have no bearing on the inheritability of mutations is, in my opinion, wilfully blind.

As to the inheritance of acquired characters, which is the other great factor in inheritance, Prof. Huxley refers to Dr. Noble's communication to NATURE of Aug. 7 on the subject of Kammerer's Alytes as if that closed the controversy. He does not refer to my answer to Dr. Noble. Since I wrote this, however, new light has been shed on this painful matter. The American journal *Science* has published verbatim the last pathetic letter which Kammerer wrote. In this letter, addressed to the University of Moscow, he explains the reason for his intended suicide. He gave full permission to Dr. Noble to examine his specimen of Alytes, believing that it would prove conclusive. He was greatly shocked at Dr. Noble's conclusion that it had been 'doctored' with Indian ink. He examined it himself and confirmed Dr. Noble's finding, and sadly acknowledged that the evidential value of this particular specimen had been destroyed. But he found also *that many others of his specimens on which Dr. Noble had not reported had been similarly treated*, and that all the fruit of his pre-War work, which would require twenty years to repeat, was gone. He did not feel the energy to begin all over again and so ended his life.

Dr. Przibram and the colleagues who knew Kammerer best, continue to have full confidence in him and are getting up a fund to perpetuate his memory. Perhaps Dr. Noble could throw light on the source from which he obtained the information that he would find the specimen of Alytes treated with Indian ink, as that might help us to discover the miscreant who, to damage Kammerer's credit, destroyed his life-work behind his back.

In conclusion, I should like to say to Prof. Huxley that the game of the mutationist opposition to

Lamarckism is up. Evidence in favour of Lamarckism is pouring in from all quarters. I direct his attention to the recent work of Metalnikoff in the Institut Pasteur, who, experimenting with the caterpillars of the genus Galleria, showed the inheritability of acquired immunity. This work was continued for nine generations under standardised conditions with adequate controls. E. W. MACBRIDE.

Imperial College of Science,
South Kensington, S.W.7.

DURING the past twenty years I have made several contributions to the evidence in favour of the chromosome theory of heredity, the last in 1926. I am not nearly so sure as I was of the universal validity of that theory, and I hope that even in my callow youth I was never so dogmatic about it as is Prof. J. S. Huxley in his review of Prof. Noël Paton's book (NATURE, Dec. 25, p. 902). I feel that some protest should be made lest the constant repetition of certain dogmatic statements by Prof. Huxley and others of the same school should lead to a general belief that these statements represent proven facts accepted by all biologists who are familiar with this particular branch of knowledge.

When the mode of distribution of the chromosomes to the daughter cells during the production of the gametes is compared with the manner in which the Mendelian characters appear in breeding experiments, the coincidence seems at first sight to be overwhelmingly in favour of the chromosome theory, so much so that it appears to have blotted out every other point of view to many people. To me, however, it appears to give us no more than the right to assume that the appearance of certain characters or groups of characters may possibly be determined by certain chromosomes. Prof. Huxley has stated before, and states again in his review, that the "hereditary constitution of at least all higher organisms consists of a number of units (factors or genes), each of which may exist in a number of forms (allelomorphs); these genes exist in definite proportions, and are arranged in a definite order; the whole gene-complex is divided up amongst the separate chromosomes." He states these as proven facts which are thoroughly established, and not questioned except by those who are unaware of these claims, amongst whom he apparently places Prof. Paton.

Anyone who has dissected a chimpanzee must have been struck by the extraordinary similarity between its characters and those of man, similarities that extend to small branches of particular blood-vessels and nerves and to folds in the skin. If we believe in evolution of any kind we must believe that the bulk of our characters have come to us from remote prehuman ancestors through countless generations, all the individuals of which developed these characters in turn, and that the appearance of these characters depended upon their "hereditary constitution." I must point out, at the risk of being platitudinous, that it is only the capacity for developing a character under certain very limited conditions, and not the character, that is inherited.

Now to me it is difficult to imagine how all the characters in a complicated organism such as man can be conveyed by units or genes which are contained in individual chromosomes. The very mechanism that makes the theory fit so well with the appearance and disappearance of certain characters in successive generations in Mendelian experiments, is an obstacle when the fact is kept in mind that most characters are common to all individuals of the race. In the one case a given character appears in a certain proportion of the offspring and does not in the rest; in the other the character appears in all.

It may be claimed that what I describe as characters are not characters in the sense intended by Prof. Huxley. In what, then, are they different except in degree? To me it appears that the presence of a head, of ten fingers, extra digits, the colour of the eyes, the shape of the section of the hair, the colour of the skin, and such diseases as hæmophilia in man are all of them due to the hereditary constitution of the fertilised ovum and the action upon it of the environment. But it also appears to me that we cannot place all these characters in the same category as regards their mode of inheritance. Some might be due to units carried by individual chromosomes, others would of necessity appear to be conveyed by a potentiality in the cell elsewhere than in the chromosomes, when we consider how these are distributed during the production of the gametes.

My own belief is that the Mendelian mode of inheritance is confined to comparatively recent variations, and this belief is the more acceptable to me in that it provides for the ready elimination of the useless variations, as important a factor in evolution as the preservation of the useful.

I see that Prof. Huxley in his review limits himself to "at least all higher organisms" as regards his view of the chromosome theory, a limit I have not noticed that he has made previously. I quite appreciate why he has done this, but I think that it would have been wise to have pointed out that there is a number of organisms in which the distribution of the chromosomes is such that they could not possibly convey a Mendelian character (Dobell, *La Cellule*, t. 35, 1 fasc. 1924, and others.) This being the case, the function of the chromosomes in these organisms must be something entirely different from what it is in the higher organisms, to me an entirely unwarrantable assumption. CHARLES WALKER.

Television.

THE article headed "Television" which appeared in NATURE of Jan. 15, contains the following statement: "a difference of phase of only one degree is capable of spoiling definition." Were this statement true, my television system, depending as it does on synchronism, would certainly, as the writer states, be faced with a very serious barrier. It is, however, a misstatement of fact. Phase difference between receiver and transmitter has no effect whatever upon definition, the whole effect being a displacement of the image as a whole.

Later in the article a statement is made: "The recent claims to have transmitted 'outlines' by infra-red rays mark no advance toward television with diffusely reflected light." This is an erroneous statement. I have on no occasion made claims to have transmitted 'outlines' by infra-red rays. What I have actually demonstrated is the transmission of real images of living faces in complete darkness, using diffusely reflected infra-red rays.

An open invitation was extended to members of the Royal Institution to witness these results, and on Dec. 30, 1926, some forty members of the Institution were given demonstrations at our laboratories. Among those who have witnessed demonstrations I may mention Dr. Russell, Mr. R. W. Paul, and Mr. Creed, who are, I think, sufficiently well known in the scientific and engineering world. In these demonstrations one party remained in a totally dark room; the second party, in a different, were then shown the faces of any of the first party who cared to sit in front of the transmitting apparatus in the dark room.

My discourse at the exhibition of the Physical Society is criticised and the statement made that it was "not the way to convince a sympathetic audience of experts." I was requested by Dr. Rankine, the secretary of the Society, to deliver a lecture suitable for a public audience interested in scientific matters generally, but not experts on television. The lecture was therefore of a semi-popular type and in no way intended for an "audience of experts."

While the writer of the article in Nature appears to be dissatisfied, judging by the reception which the lecture was given and the appreciative letters which I have received, I am assured that opinion was not shared by the bulk of the audience.

I am further criticised for withholding technical details. The writer of the article is surely aware that my inventions are the property of a limited company. The disclosures by me of technical details likely to assist competing interests would therefore be a grave breach of trust to the shareholders. I may further add that we have demonstrated the invention to Government experts, and have received a letter from the Government requesting us to withhold publication of technical details.

The writer states further that: "There are at least three pioneers in the field who appear to be on the verge of a complete solution of the television problem," and mentioned Belin, Jenkins, and Alexanderson. The results which, according to press reports, they have demonstrated should be mentioned. Belin and Jenkins have succeeded in transmitting crude shadowgraphs; and Alexanderson, within the last few weeks, apparently claims to have achieved the same feat. This is a long way from television, and does not justify the statement that they appear to be on the verge of a complete solution of the television problem.

John L. Baird.

Television Limited, Motograph House,
Upper St. Martin's Lane, London, W.C.2,
Jan. 19.

The further information given above by Mr. Baird is precisely the kind which physicists were waiting for. In the absence of a clear description in technical language, many misconceptions are bound to arise, and it would be well for Mr. Baird to consider the advisability of making such a communication at the earliest opportunity consistent with his other obligations.—Editor, Nature.

The Auroral Green Line 5577.

Messrs. McLennan, McLeod and McQuarrie have published in Nature, vol. 118, page 441 (Sept. 25, 1926) the results of some recent experiments on the origin of the auroral green line 5577. During July and August last, while a guest of the Nela Park Research Laboratory, at the kind invitation of Dr. W. E. Forsythe, I had the opportunity of investigating spectroscopically the electrical discharge in mixtures of (1) helium with oxygen, and (2) argon with oxygen. The relative proportions of the two gases in each mixture were varied as well as the current through the gases. In the case of helium with oxygen, traces of this green line were found on some plates, but its intensity was usually very feeble. In one experiment, however, with argon and oxygen, the line 5577 appeared very strongly, about one-half the intensity of the argon line 5559, the iron arc spectrum being used for comparison (Fig. 1. I am indebted to Prof. Lloyd for the enlargement).

The discharge tube was made of pyrex tubing 8 mm. in internal diameter, and was fitted with tungsten electrodes which had been 'outgassed' before introducing the mixture of argon and oxygen (argon pressure = 40 mm., oxygen pressure = 8 mm.). The tube was of H-form, and the discharge was viewed along the bar of the H with a Hilger quartz spectrograph of the D type. The current used was 80 milliamp./cm.^{2}, and the potential 800 volts.

When the tube had run for one and a half hours, a second photograph was taken on which the line 5577

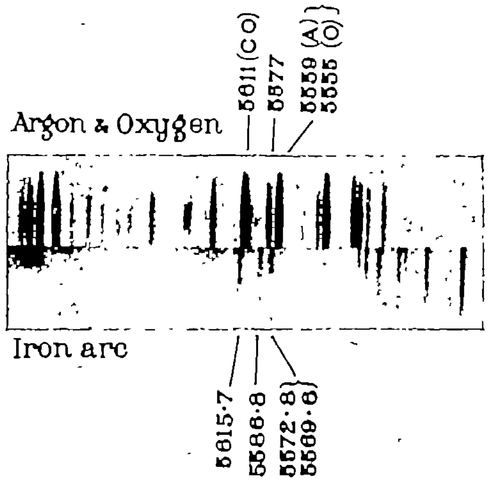

Fig. 1.

was entirely absent. The oxygen had combined with the tungsten, forming a bluish deposit of tungsten oxide on the glass near the electrodes. This result confirms the recent work of McLennan and his co-workers, and the absence of the line when the oxygen was removed is further evidence that the line is primarily due to the oxygen.

The Polishing of Surfaces.

Mr. Macaulay and Mr. Preston, in their letters in Nature of Sept. 4, 1926, and Jan. 1, 1927, raise the interesting question of the mechanism by which the surface layer is produced in the process of polishing. This layer, so thoroughly studied by Beilby, resembles a supercooled liquid so nearly that it has been suggested that the surface layers are liquefied.

It does not seem necessary to suppose that actual liquefaction occurs. An amorphous layer indistinguishable from a supercooled liquid will be formed by any mechanism which rearranges the surface molecules at random. The polisher adheres to the surface, and especially with the high coefficient of friction mentioned by Mr. Preston, will tear away the surface particles of the glass when it is moved. Hardy found the surface of solids to be torn by the mere motion of a slider. Some of these particles will naturally be redeposited elsewhere at random, thus forming the amorphous layer. Some of the particles torn away must be of molecular dimensions for the final result to be a completely amorphous layer.

Surface tension in the ordinary sense does not enter into the problem, but since the flat, liquid-like surface is that of least potential energy possible in the circumstances, molecules are more likely to be deposited as part of such a surface, and less likely to be removed from it, than otherwise. The crystalline state, of still less potential energy, will not be formed, as sufficient time is not allowed in the redeposition of particles. This mechanism is actually more likely to produce a completely amorphous layer than liquefaction, for the resolidification of a liquefied surface layer might result in the formation of small crystals.

In his article on 'Polish,' the late Lord Rayleigh concluded that the material is worn away 'almost molecularly.' Some redeposition seems necessary in order to account for the amorphous layer. Probably the polishing, as distinct from an abrading agent, tends to remove particles of molecular dimensions; and the yielding nature of the support frequently used assists the molecules or atoms adhering to the polisher to come frequently into close contact with the glass or metal, and thus promotes redeposition.

Fine Structure of the Balmer Lines of Hydrogen.

Using two optical trains, (1) two crossed Lummer plates, the larger of resolving power 670,000, and (2) an echelon of resolving power 660,000, with a vacuum tube of the Wood form having a 1 cm. diameter capillary, cooled with liquid air, we have determined the wave-length differences between the two well-known components λ' and λ'' of H_α, H_β, and H_γ ($\lambda' < \lambda''$), and have sought to obtain still further resolution. The doublet separations are shown in the subjoined table together with those given by Houston (*Astrophys. Jour.*, 64, 2, 1926, pp. 81-92), which latter are, in our estimation, the most trustworthy thus far obtained.

Our values are somewhat higher, but this possibly is not to be wondered at, because of the different current densities employed, 250 against 25 milliamperes per sq. cm. A very trustworthy Lummer plate spectrogram, taken at 13 milliamperes per sq. cm., yields 0·1391 for H_α, which is in harmony with such a current change.

The search for other components revealed a third on the longer wave-length side of λ'. This component is not fully resolved but is clearly present. Moreover, λ'' is distinctly narrower than λ', and under the discharge conditions employed is somewhat more intense. λ' of H_β also shows an asymmetry of the same nature but about one-half as great. Hansen (*Ann. der Physik*, 78-6, 22, pp. 558-600, 1925) has noticed asymmetries in both these cases.

$\Delta\lambda$ in Tenth-Metres.

Line	Houston. (250 ma./sq. cm.)	Kent, Taylor, and Pearson. (25 ma./sq. cm.)	(13 ma./sq. cm.)
H_α	0·1358	0·1370	0·1391
H_β	0·0782	0·0791	..
H_γ	0·0665	0·0669	..

Ionisation Phenomena in Active Nitrogen.

In some recent experiments with active nitrogen, it has been found that ionisation effects differ with the gases mixed with the nitrogen. When the active nitrogen alone was drawn past an ion trap into cylindrical condensers, the negative charges obtained were found to be proportional to the areas of the negative electrodes, indicating that the conductivity is due to photo-electrons emitted from the electrode and not to the production of free ions in the gas. The same observations were made when hydrogen and mercury were added to the active nitrogen before it entered the condenser. With iodine (ionisation potential 9·4 volts), however, a different ratio of currents was obtained, showing that ionisation is produced in the gas. This suggests that the phenomena associated with active nitrogen may be due to a metastable state of the nitrogen molecule with energy between 9·4 volts and 10·4 volts. The effect of various gases on the deviation of the after-glow was examined, the most important result being that it is not affected by helium when the helium is made ten times the density of nitrogen.

Ph. A. Constantinides.

Ryerson Laboratory,
University of Chicago,
Dec. 17.

It may be remarked that I showed long ago that the ionisation associated with the decay of active nitrogen was dependent on the gases mixed with it (*Proc. Roy. Soc.*, vol. 86, pp. 60, 61, 184, 1911–12). In particular, sodium vapour greatly increased the effect obtained with nitrogen alone, and oxygen or nitric oxide greatly diminished it. Mercury had little effect, as in the experience of Mr. Constantinides. The views expressed by him scarcely seem adequate to cover all the above facts. But the subject is doubtless well worth pursuing, with the much greater theoretical illumination of the present time.

The Problem of Secretion.

The summary of Bowen's recent discussion of the cytology of secretion in Nature of Jan. 1, p. 30, fails to do justice (as Bowen himself has done in his papers) to the contribution of other workers to this difficult subject.

The earlier work of Golgi, D'Agata, Cajal, and Da Fano, and the investigations of Bowen's immediate predecessors and contemporaries, Nassonov, Brambell, Ludford, and Cramer, contribute so materially to the establishment of our present state of knowledge, that the impression conveyed by the summary in Nature that this work is solely the achievement of Bowen is, we feel, unfair to the other investigators mentioned. As representing the institutes in which much of the work in Great Britain has been carried out, we think that this article should not be allowed to pass without comment.

Jan. 4.

Most of the short notice referred to was prepared as paragraphs for "Research Items," which accordingly were intended to be simply a summary of the position of the problem as presented by the author. The paragraphs were afterwards arranged, with little modification, in the form of a short notice. This was offered as a brief statement, not for the specialist but for the more general reader, of the present position as set forth in one of the latest accounts of the subject; it was not intended to be a review of the literature of the problem. Such a review, which would need to be much more extensive, would, of course, take full cognisance of the previous investigations referred to in the above letter.—Editor, Nature.

Popular Long-Range Weather Forecasts.

THE 50-day weather forecasts published in the *Daily Mail* have attained such popularity that an authoritative pronouncement from science as to whether they have or have not any real value has become desirable, and Capt. Cave is to be congratulated on opening an investigation on the subject.

The principles on which the curves are prepared are largely empirical, so that it is only by long-continued comparison of expectations with facts that their dependability can be estimated or improvement can be effected. Their preparation entails a large amount of labour and involves the maintenance of an office with technical assistance. They have never received the support of official meteorology, so that, without the public-spirited enterprise first of the *Field* and now of the *Daily Mail*, the work could not have been carried on. From the point of view of science, two consequences of this are unfortunate:

(1) The form in which they appear is popular rather than scientific.

(2) It has not been possible to publish full details of the methods used without disloyalty to those who have backed them.

Before trying to compare the expectation diagrams with facts, it is necessary to be quite clear as to what is aimed at in them. Since they are published for popular use and not for scientific study, the explanation given with them is not so complete as a scientist might wish. It is stated that—

(1) Nothing approaching infallibility is claimed.

(2) The diagrams indicate the expectation of rain; the higher the curve the greater the expectation.

(3) The curves are not intended as day-to-day forecasts, and their author is quite satisfied if the timing of his expectations is correct within 24 hours either way.

This was explained in some detail, but in popular form, in the *Daily Mail* of April 30, 1926.

For the benefit of more scientific readers their author would like to add:

(4) The datum line and the shaded and blacked areas are intended only as a guide to the eye and have no precise significance.

(5) While the curves primarily indicate degree of expectation, it is reasonable that they should also show some relation to rain amounts. At one time the investigations were based on rain or no-rain, 50 mm. being counted as exactly the same as 0·2 mm., but now (as from June 17, 1926) the factor of amounts has been introduced into the expectations, and their author aims at checking his results for each station by plotting the actual rain amounts to the vertical scale shown in the following table, which is roughly proportional to the logarithms of the amounts. It will be realised that this is an extremely searching test, and one which even 12-hour forecasts would not be able to stand.

(6) The diagrams for the British Isles as a whole show the extent to which rain is expected to be general over the British Isles.

Rain Amount	Vertical Scale.
Nil	− 2 units
Up to 0·1 mm.	− 1 ,,
,, 1·0 ,,	0 ,,
,, 2·0 ,,	+ 1 ,,
,, 5·0 ,,	+ 2 ,,
,, 11·0 ,,	+ 3 ,,
,, 25·0 ,,	+ 4 ,,
,, 56·0 ,,	+ 5 ,,

It is to be regretted that Capt. Cave did not study the *Daily Mail* of April 30, 1926, or communicate with the author of the diagrams before making his tests, for it will be seen that neither his "weather numbers" nor his "forecast numbers" are appropriate. Both his criticism and his diagrams, therefore, being based on those numbers, fail to apply.

Further, since the complete set of curves is made for the 50 days independently every week, each one has a character of its own, and should be considered as a whole. To select the fourth to the tenth days out of each 50 for criticism is like criticising a 12-hour forecast by examining the weather for an interval of 103 minutes out of each day. For this reason, too, the comparison made in Capt. Cave's diagrams is not a fair one.

The *Daily Mail* curves are based on the combination of fifteen cycles which are selected for each of the four stations every week. Some of these cycles are well known, and no originality is claimed for them; others have been developed for this special purpose, and have stood the test of time; others again are still in the experimental stage. The method of selecting the cycles depends partly on permanent factors, which can be anticipated for any length of time ahead, and partly on temporary factors, which may change from time to time. While, therefore, some of the cycles usually remain the same from week to week, often changing conditions introduce new ones, causing more or less variations in the expectation curves. Such variations do not seem unscientific or in any way unreasonable. They must be admissible even in a 12-hour forecast—if a forecaster at 8 A.M. expects a heavy shower at 2 P.M. and at noon modifies his forecast and expects a moderate shower at 3 P.M. instead, we do not regard him as a fraud or his forecasts as worthless. Whether or not the diagrams under discussion are invalidated by the modification is a question of degree which can only be decided by a careful comparison of a series of complete diagrams over a long period.

For this purpose two sets of diagrams are here shown. Fig. 1 is a series of ten expectation curves as published in the *Daily Mail* for the British Isles as a whole, covering the period June 18–Oct. 7, 1926. This series is a fair average sample, and it shows the extent of the weekly variation in the curves for the British Isles; at individual rain gauges obviously somewhat greater variation must be expected. As a convenient check on the results, a curve of facts has been added in which the ordinates are made proportional to the number of rain gauges, out of the 43 British reporting stations, which have recorded rain (0·2 mm. or more) during the 24 hours.

Fig. 2 is a series of five expectation curves for the Scilly Isles, covering the period July 2 – Sept. 16, 1926, together with a curve of facts plotted according to the logarithmic scale explained above. This series is selected from among those which Capt. Cave criticised, and is perhaps above the present average of achievement.

Such a juxtaposition of a series of expectations with facts seems to be the only fair and conclusive method of testing them; but it will be seen that the method is a severe one, and it will perhaps be agreed that, if any series of 12-hour forecasts were graphed in the same way and checked for every quarter hour, they would probably not compare with facts nearly so well as these do.

The diagrams for the Scilly Isles were also tested on the basis of day-to-day expectations checked with rain or no-rain facts, and the degree of success attained was compared mathematic-

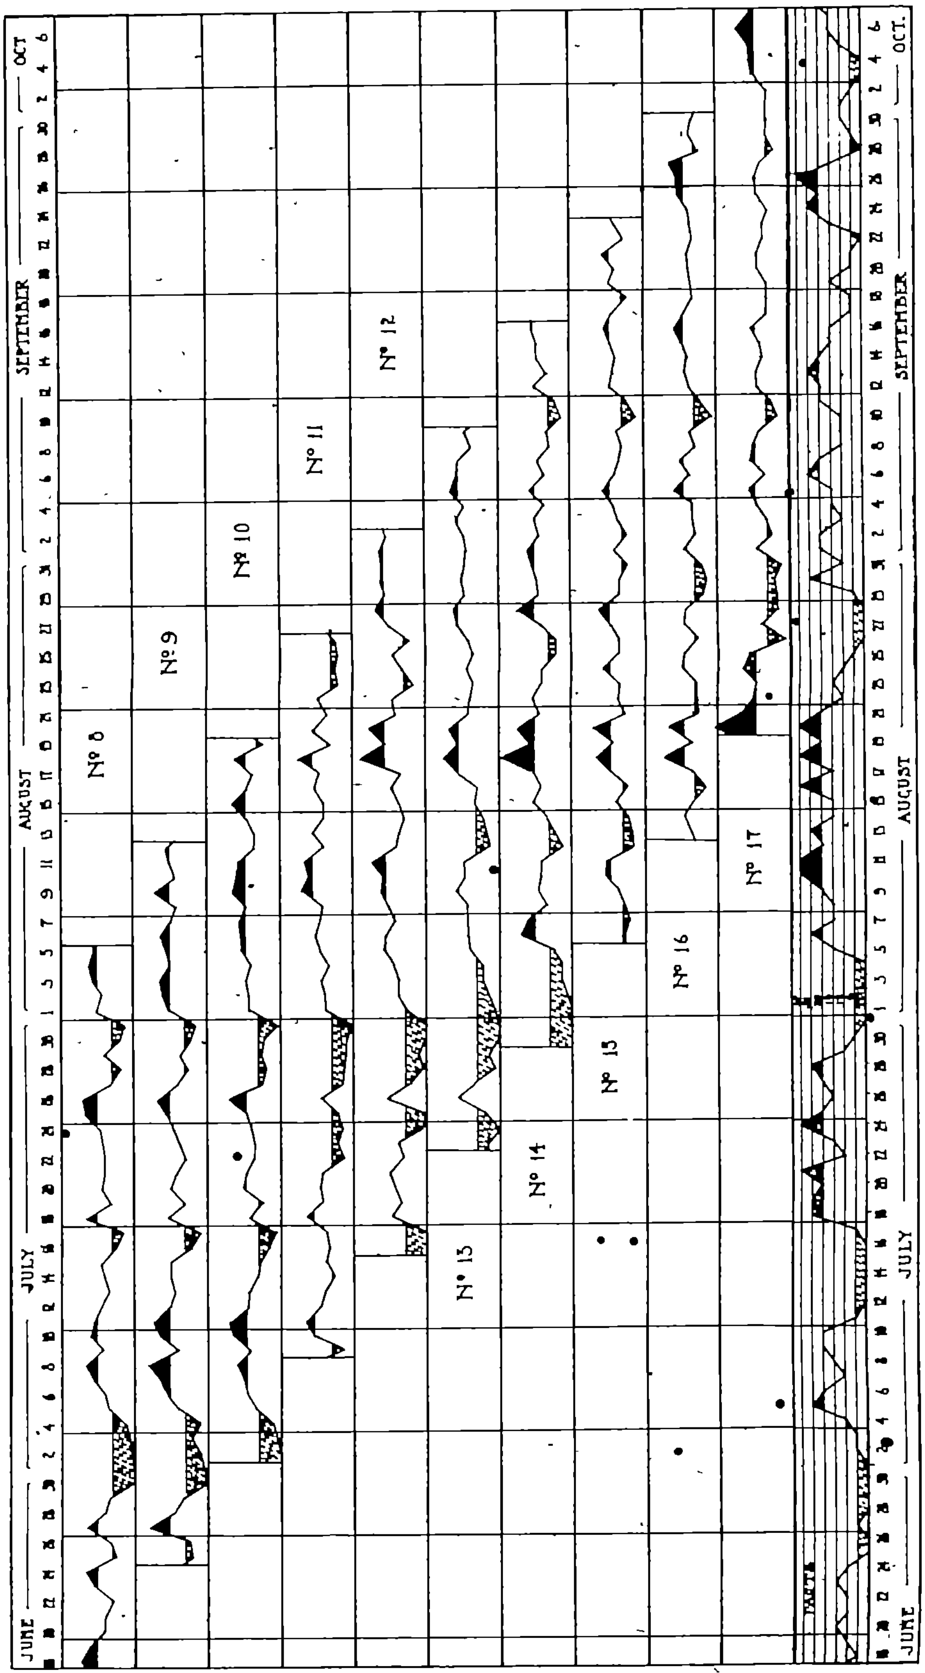

Fig. 1.—Great Britain and Ireland. Comparison of *Daily Mail* charts with observations of ten diagrams for 1926.

ally with what might be expected of a random guesser.

The data were obtained as follows: In each published curve, each day which was shown blacked was regarded as a rain expectation; if 0·2 mm. or more of rain was officially recorded that day, it was considered a success; if less than 0·2 mm. of rain, a failure. Similarly, each day which was shown shaded was regarded as a no-rain expectation; if less than 0·2 mm. of rain was officially recorded that day, it was considered a success; if 0·2 mm. or more, a failure.

In the diagrams for the Scilly Isles shown in Fig. 2, the rain expectations have been marked with an arrow pointed upwards, the no-rain expectations with an arrow pointed downwards. It should be mentioned that the published diagrams always begin on a Friday, but, since they are completed and leave their author's hands on the Wednesday, for the purpose of his own checking he always includes the Thursday's expectation, which is not published, and it has been done for the purpose of this check too. This is slightly to his advantage, for 12 definite expectations for the first Thursday are included in the series here considered, and of these 8 were successes and 4 were failures.

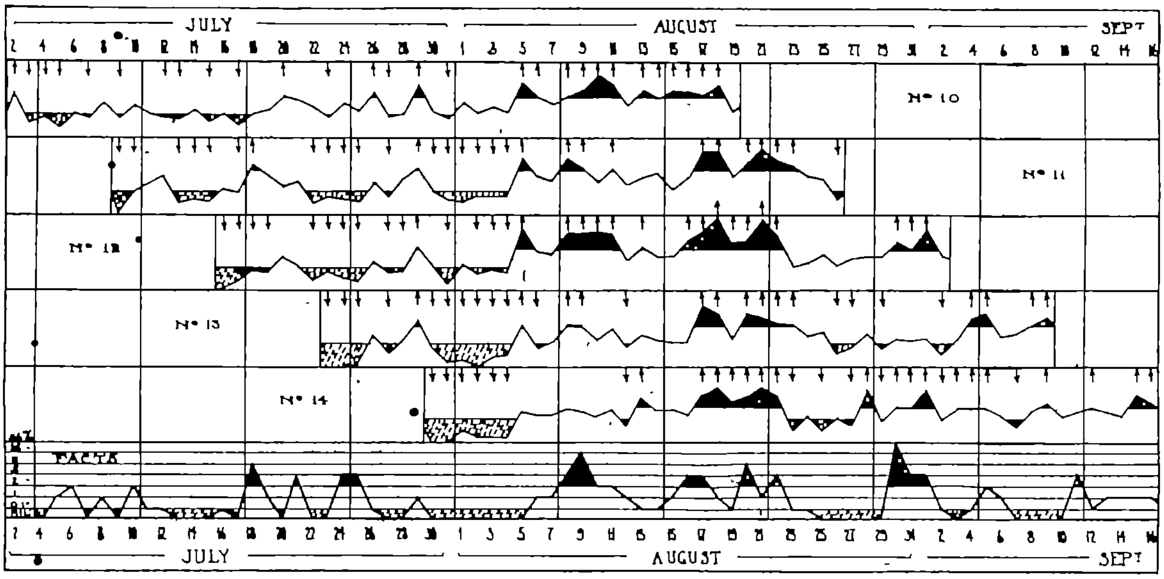

FIG. 2.—Scilly Isles. Comparison of expectations with observations, 1926

Over the period June 17–Dec. 3, 1926, for the Scilly Isles 640 definite expectations were made. Of these, 412 were successes and 228 were failures on the day-to-day basis explained above. At first sight this may not seem a very striking measure of success, and for a small number (say 12 expectations) such a proportion could reasonably be attributed to chance; but for 640 expectations, the odds against a random guesser making 412 successes are incredibly large. If any one doubts it, let him try spinning a coin 640 times, and he will find that he never gets anything approaching 412 of either heads or tails.

The odds against the random guesser were tested according to the theory of probability. Given that the facts for the days considered were 348 rain and 292 no-rain, also that the guesser makes 640 guesses, knowing that the normals for the period are 95 rain and 74 no-rain, so that he would guess rain 360 times and no-rain 280 times.

Assuming the above data only:

The chance that the guesser would get exactly 412 successes is

$$\frac{\underline{|348} \times \underline{|292} \times \underline{|360} \times \underline{|280}}{\underline{|240} \times \underline{|108} \times \underline{|120} \times \underline{|172} \times \underline{|640}} = 7{\cdot}00 \times 10^{-13}.$$

By adding the chances of more than 412 successes we get $1{\cdot}01 \times 10^{-12}$.

The odds are therefore $9{\cdot}90 \times 10^{11}$ to 1 against a random guesser scoring 412 or more successes under the conditions assumed.

These calculations were made by Mr. W. Hope-Jones, of Eton College, and confirmed by Dr. R. A. Fisher, of Rothamsted Experimental Station.

Admittedly there may be factors which perhaps ought to be included, and might, if included, reduce this figure, but it would appear that, in whatever way the problem may be tackled, the odds against a random guesser doing so well are practically infinite.

The expectations and facts may be tabulated as follows:

	Expectations.		
	Rain	No Rain	Total.
Rain Facts . .	243	105	348
No-Rain Facts .	123	169	292
Total	366	274	640

It has been the purpose of this article to show that—

A. Owing to the popular form in which these expectations are produced, Capt. Cave formed an erroneous conception of their aims, so that his arguments were unsound and his conclusions misleading.

B. A careful examination of a series of diagrams indicates that

(1) Variations from week to week are not great, and generally tend towards improvement as time advances.
(2) Although it is not claimed that rain amounts are correctly anticipated, the peaks and dips of the expectation curves correspond with those of the facts curve in many cases to the actual day, and in most cases to within 24 hours.
(3) There is a degree of correspondence between expectations and facts which cannot be wholly due to chance.

C. The above is confirmed definitely and conclusively by the calculations based on the theory of probability.

If these propositions are accepted, and it would seem hard to dispute them, then it must be agreed that the claims made in the *Daily Mail* are more than substantiated, and that what Capt. Cave condemns as no better than fortuitous prediction has been proved to be something of the order of a billion times better, and represents in fact a notable advance in meteorological science.

R. P. BUTLER.

CAPT. BUTLER complains that my weather and forecast numbers are unfair, and appeals to the *Daily Mail* for April 30. The only relevant sentence seems to be that the greater the height of the curve above the datum line the greater the probability of rain, but not necessarily the amount of rain; I do not think that this fact invalidates anything I have said. I have already explained the method of comparing the forecast diagrams with the weather, and I am quite content to leave it to the readers of NATURE to say whether the method is fair or unfair.

It is also said that the forecasts are not meant to be day-to-day forecasts; they are, however, given in a day-to-day form, and are, I think, generally so taken by the public; Capt. Butler, however, emphasises the point and says that the author is quite satisfied if the timing of his expectations is correct within twenty-four hours either way. The number of wet days with 0·04 inch of rain or more is about 120 in the year for the south-east of England, or one day in every three; any one forecasting rain for to-day and claiming a success if rain comes yesterday, to-day, or to-morrow, is putting his forecast in a very favourable position. If one were to forecast by drawing counters out of a bag, the successes under the above conditions would be very marked.

I do not understand Capt. Butler's complaint that I only took one forecast for each week for the purpose of comparing them with the weather in my diagrams. I took the complete week nearest to the actual happenings as being the most fair to the author. Capt. Butler says that each 50-day forecast has a character of its own, which is exactly what I maintained. I have selected one of the seven varying forecasts for each week and compared it with the actual weather, and I have done this for the whole period from April 15 to Oct. 27. To say, as Capt. Butler does, that doing this is like "criticising a 12-hour forecast by examining the weather of 103 minutes out of each day," seems to me to be a statement devoid of meaning. If the forecasts are in the main similar, there is nothing unfair in taking any one in preference to the six other forecasts for the same week; if they differ, it is reasonable to suppose that the one nearest to the period for which the forecast is made would be the most correct; I therefore took the first complete week of the latest forecast. Capt. Butler's diagrams show exactly what I maintained, that the forecasts for each week vary so materially as they are issued week by week that they cannot all be guides to the coming weather. Nor are his diagrams of facts compared with forecasts very striking. I pointed out that August was a particularly favourable month for the forecasts, especially in south-west England; I do not see anything very remarkable in the diagrams as extended to July and September.

The method of the forecasting is still wrapt in obscurity on the plea that to disclose the method would be an act of disloyalty to those who have backed the forecasts. Such an attitude to scientific truth has probably never before made its appearance in the pages of NATURE. It precludes one from examining the worth of the forecasts except in so far as the results declare it, and nothing that Capt. Butler has brought forward changes my opinion that chance operates largely, if not entirely, in the relation of forecasts to facts. His probability figures do not impress me very much. He has evidently treated each of the seven weekly forecasts as entirely independent, which he himself claims not to be the case. If they were not treated as independent variables, I fancy that the impressive figures he brings forward would dwindle to very modest proportions. In any case he has attempted to prove too much; if the forecasts are a billion times better than would be expected on pure chance, failures should practically never occur, whereas it is obvious, even from his own selected diagrams, that the method cannot be relied on by the farmer for his agricultural operations, or by the man in the street who wants to know whether or not to take out his umbrella.

C. J. P. CAVE.

Obituary.

GENERAL SIR CHARLES WARREN, K.C.B., G.C.M.G., F.R.S.

GENERAL SIR CHARLES WARREN, the distinguished soldier and archæologist, died on Jan. 21, in his eighty-seventh year. Born on Feb. 7, 1840, he was educated at Cheltenham College, Sandhurst, and Woolwich, passing into the Royal Engineers in 1857. He had a distinguished career both as technical officer and as a military commander in South Africa and Egypt. He commanded a column in the Boer War, and was afterwards in command of the troops at the Straits Settlements.

Like his fellow-soldiers, Gordon, Kitchener, Watson, and Wilson, Warren was greatly interested in research in Palestine. This brought him into touch with the founders of the Palestine Exploration Fund, and from 1867 until 1870 he conducted excavations at Jerusalem and made a reconnaissance of Palestine on behalf of that Society. Notwithstanding much opposition on the part of the local authorities and the difficulty of raising funds, he accomplished valuable work. This bore fruit in a number of publications. He was author of part of "The Recovery of Jerusalem: Underground Jerusalem," 1876, "The Temple and the Tomb," 1880, and the Jerusalem volume of the Survey of Palestine, with a portfolio of plates and excavations (1884). He had also devoted much attention to the question of ancient standards of measurement, and published "The Ancient Cubit and Weights and Measures" in 1903, and "The Early Weights and Measures of Mankind" in 1914. His connexion with the Palestine Exploration Fund continued throughout his life and he was for some years a member of the committee. This association had brought him closely into touch with Sir Walter Besant, secretary of the Fund. With him he founded the Quatuor Coronati Lodge of Freemasons, the object of which was masonic research, and Warren became its first Master.

WE regret to announce the following deaths:

Mr. W. M. Chauvenet, consulting chemist and mining engineer, who worked at the chemistry of ores and at structural and mining geology, aged seventy-one years.

Dr. Karl Hell, emeritus professor of general chemistry at the Technische Hochschule in Stuttgart, who died on Dec. 11, aged seventy-seven years. He was the author of numerous publications in organic chemistry.

Dr. Herbert A. Howe, dean of the college of liberal arts at the University of Denver and director of the Chamberlin Observatory at the University, who was known for his work on the positions of nebulæ and on comets and asteroids, aged sixty-eight years.

Mr. Daniel Irving, president in 1904 of the Institution of Gas Engineers, and chief engineer for many years of the Bristol Gas Company, on Jan. 12, aged seventy-one years.

Mr. John Webster, senior scientific analyst to the Home Office, who had published several papers on arsenical poisoning and on the toxicology of salvarsan, on Jan. 20, aged forty-nine years.

News and Views.

BEFORE publishing in NATURE of Jan. 8 the article by Capt. C. J. P. Cave on "Popular Long-Range Weather Forecasts," we sent an advance proof to Lord Dunboyne, whose fifty-day forecasts are published in the *Daily Mail* and formerly appeared in the *Field*. Lord Dunboyne desired to reply to the article but found himself unable to do so, and he therefore entrusted his case to his brother, Capt. the Hon. R. P. Butler, whose article appears elsewhere in this issue, together with Capt. Cave's comments upon it. Having now devoted a fair amount of our congested space to the subject we think no more can reasonably be expected, and our readers may safely be left to form their own conclusions upon the evidence which has been placed before them. We are, of course, glad to give Lord Dunboyne credit for a desire to discover principles by which long-range weather forecasts may be secured, and we should be sorry to discourage him or any one else working to achieve this aim. We must point out, however, that the appropriate place to present such principles is a scientific society, like the Royal Meteorological Society, where they would be discussed by people best able to express a judgment upon them. It is of no use to say, as Sir Theodore Cook, the editor of the *Field*, does, in a letter to us, that while Lord Dunboyne contributed the forecasts to the columns of that journal he received "the most satisfactory letters from farmers and correspondents of every kind in all parts of England." Science is not concerned with belief when processes of Nature are involved, but with evidence; and no principle or theory ought to be recognised in scientific fields unless it can survive critical discussion. When Lord Dunboyne's methods and results are submitted to such a bar of competent opinion, we shall be glad to render a further account of them.

OUR leading article of Sept. 4, 1926, on Prof. Graham Kerr's presidential address to Section D (Zoology) of the British Association at Oxford, has moved Mr. George H. Bonner to return to the subject of the advantages of a classical education in the *Nineteenth Century* for January. The author excuses himself for attempting to revive "so hoary a subject" on the ground that the question of the rival merits of 'classical' and 'scientific' is among the most vital that can be propounded, and that when the subject is thoroughly analysed it may appear that only the fringe has been touched and the real reasons for a preference overlooked. Education, as Mr. Bonner conceives it, is to confront the mind with truth in such a manner that it is immediately recognised and becomes a conscious possession. Broadly speaking, the line of argument taken is that science being confined to observed facts and 'laws,' which are merely theories subject to change with the advance of knowledge, does not deal with truth in the sense of the apprehension of 'purpose' and the ultimate realities of the universe and God—the essential element in the training of the higher faculties of man and the development of the power of reasoning.

MR. BONNER goes on to point out that even the 'practical' advantage, usually urged in favour of science, really lies with the classics, which induce an acquaintance with a wide variety of topics and a flexibility and adaptability of mind not to be acquired by a study of facts and the 'laws' of science. In this connexion it is of interest to refer to the closely parallel argument in favour of university education generally in a recent letter to the *Times* in reply to a criticism of the capabilities of university men in business, where it was pointed out that during the War it was pre-eminently a university training which produced the qualities of flexibility, adaptability, and ready accommodation to individuals and circumstance, requisite in the officer trained under stress of emergency. Whether or not we are prepared to follow Mr. Bonner in attributing the individual qualities of Greek literature to the influence of Egypt, it will be allowed that he takes up a strong position when he holds in relation to his main line of argument that the classics form collectively an expression of truth more complete than any literature in the world, enabling man "to see things as they are and not as they seem to be." Mr. Bonner, however, misunderstands our article if he imagines that we discount the value of the teaching of science. To point out where the discipline has failed is not to condemn it but rather to help it to achieve those results which, as a unit in a properly balanced system of education, we know it can produce.

THE Geological Society of London has recently announced the following awards: The Wollaston medal to Prof. W. W. Watts, who has distinguished himself by his work on the ancient rocks of the Charnwood Forest, the igneous rocks of the Midlands, and the stratigraphy of the Welsh border, especially Shropshire. The Murchison medal to Dr. G. T. Prior, Keeper of the Department of Mineralogy in the British Museum (Natural History), who is distinguished especially for his work on the chemical composition of meteorites. The Lyell medal to Sir Albert Ernest Kitson, Director of the Geological Survey of the Gold Coast, where he has distinguished himself by the discovery of manganese, bauxite (aluminium hydrate), and diamonds. The manganese proved to be of considerable importance, especially during the War. The Bigsby medal to Dr. Bernard C. Smith, of the Geological Survey, who has done good work in the Midlands, Cumberland, and north Wales, including some interesting researches on the former courses of rivers and on ancient swallow holes. The Wollaston Fund to Miss M. E. J. Chandler, who, both in conjunction with Mrs. Clement Reid and independently, has made considerable additions to our knowledge of Tertiary and Pleistocene plants by the separation and examination of seeds in sediments. The Murchison Fund to Dr. S. H. Haughton of the Geological Survey of South Africa, for his work on fossil vertebrates. One-half of the Lyell Fund to Dr. Leonard Hawkes, reader in geology at Bedford College, London, for his researches in petrology, especially on the igneous rocks of Iceland. The other half of the Lyell Fund to Miss Edith Goodyear, senior assistant in the Geological Department of University College, London, for her work on the stratigraphy and palæontology of the Carboniferous rocks.

DURING recent years city and suburban traffic has increased so rapidly that it is very difficult to provide transport facilities for it. The competition also between motor omnibuses and electric tramways has become very acute. The latter especially have been forced to improve the facilities they offer. In particular they run at higher speeds. Recent specifications for tramcar equipment demand a running speed of 25 to 30 miles an hour, which is practically double that demanded before the War. The length of the cars has greatly increased, and so also has their seating capacity. It is therefore necessary to use larger electric motors. It is usual to specify for two motors for each car, each being rated at from 50 to 60 horse-power. In pre-War tramway motors the armatures used to run at 600 revolutions per minute, whereas they now run at 900 revolutions per minute; also instead of being totally enclosed they are now self-ventilated. One important result of these changes is that the motors are both smaller and lighter, although they can exert nearly double the power. The design of tramway controllers has also been greatly improved, the large currents being broken by a powerful magnetic 'blow-out.' These controllers are used by the London County Council, and at Edinburgh, Manchester, Glasgow, and Newcastle-on-Tyne.

THE annual general meeting of the Royal Meteorological Society was held on Wednesday, Jan. 19, and Sir Gilbert Walker was re-elected president. The Buchan Prize, which is awarded biennially for the most important original papers contributed to the Society during the previous four years, was presented to Mr. C. K. M. Douglas. Sir Gilbert Walker delivered an address on "The Atlantic Ocean," in the course of which he directed attention to the value, when studying the movements of the atmosphere, of an understanding of oceanic circulations. He described the conditions of temperature, salinity, and density revealed by recent measurements in the Atlantic down to a depth of 10,000 feet or more. These throw light on the general character of the oceanic circulation, and indicate that though prevailing winds may set up surface currents, they probably produce no significant effect at a depth exceeding 700 feet. Icy water from the Arctic, and especially the Antarctic, flows towards and even beyond the equator at great depths, and as the air temperature is largely controlled by that of the sea, variations in the general circulation may provide the explanation of some of the big seasonal changes which occur in equatorial as well as in temperate regions.

PROF. A. S. EDDINGTON, Gifford Lecturer for 1927, who has chosen for the subject of his course "The Nature of the Physical World," gave the first of ten lectures at the University of Edinburgh on Friday, Jan. 21, on "The Failure of Classical Physics." The Earl of Balfour, Chancellor of the University, presided. Prof. Eddington said that in these lectures he proposed to explain some of the results of the modern study of the physical world which give most food for philosophic thought, and to show how we have been led to think of the material universe in a way very different from that prevailing at the end of the last century. He would not leave out of sight the ulterior object which must be in the mind of a Gifford Lecturer—the problem of relating these purely physical discoveries to the wider aspects and interests of the human soul. These relations cannot but have changed since our whole conception of the physical world has radically changed. He is convinced that a just appreciation of the physical world as it is conceived to-day carries with it a feeling of open-mindedness towards deeper significances behind it, which may have seemed illogical a generation ago; near the end of the course he would try to focus that feeling and make inexpert efforts to find where it leads. Prof. Eddington then proceeded to a consideration of some of the revolutionary changes in our views of space and matter resulting from the new theory of matter originated by Rutherford, and from Einstein's theory of relativity. Further lectures of the course will deal with time as a fourth dimension, the running-down of the universe, gravitation, the quantum theory, the nature of the stars, inorganic evolution, world building, the domain of physical science, and science and mysticism.

DR. R. CAMPBELL THOMPSON, in a lecture on Jan. 18 at Bedford College for Women (University of London) on "Conceptions of the Cosmos in Ancient Babylonia," pointed out that it is impossible to deal with the subject from any but a theological point of view. The early Babylonian ideas, like those of all early peoples of whom we have knowledge, were influenced by their view of the supernatural and by their geographic environment. The beliefs of the early Sumerian inhabitants of Babylonia appear to have been adopted by their Semitic successors without much change. After an introductory sketch of their mythological system between the approximate dates of 5000 B.C. and 2000 B.C., in the course of which he pointed out the traces of Babylonian influence in the New Testament, Dr. Campbell Thompson described, with the aid of a diagram, the cosmos as conceived by the Sumerian and Semitic inhabitants of the land. The earth, which was of course limited to the land of which they had knowledge, was surrounded by the ocean, which was again encircled by an enclosing dam. The three heavens above, with the lower earth and Hades beneath, comprised the universe. The sun god emerging from the mountains of sunrise in the east ran his course across the firmament and entered the earth again by the mountains of sunset in the west. A pastoral people inhabiting a flat land naturally had their attention turned to the sky and its heavenly bodies, and looked to them for omens. In the Babylonian cuneiform script, the sign for a god is the same as that for a star. Astronomical science, however, as opposed to astrology, developed at an early date. The Babylonian astronomers had sufficient knowledge to predict eclipses with some accuracy, though not the point from which they would be visible. Dr. Campbell Thompson illustrated his remarks by references to the creation and other myths preserved on the clay tablets which formed the libraries, and showed many beautiful slides both of the scripts and drawings. At the end of the lecture he delighted his audience by reading translated extracts from the Gilgamesh Epic on which he is at present at work.

SIR WILLIAM BRAGG'S discourse at the Royal Institution, delivered on Jan. 21, dealt with "Tyndall's Experiments on Magne-crystallic Action." In 1845, at the Royal Institution, Faraday made a great step forwards in the science of magnetism. He constructed a powerful electro-magnet; the core was formed from a link of a large chain cable and the heavy copper wire was wound for the occasion, because covered wire was not an article of commerce in those days. With this he showed that practically all substances have magnetic properties, and remarkable relations were found to exist between magnetic properties and crystalline structure. These results led to his conception of 'lines of magnetic force.' These lines he imagined to run not only through material substances when magnetised, but also through the space about a magnet; so that in his view it was possible to speak of the ether of space being magnetised and to measure its consequent energy. These discoveries of 1845 excited great interest and were widely repeated, extended, and discussed. Much work was done by Tyndall, whose results were interpreted by Faraday as supporting his own theories. Tyndall, however, preferred an interpretation, as did others of the same time, which laid much less stress on the part played by the ether and fixed attention on the material bodies concerned. In particular he subjected bodies to great pressure, and showed how their magnetic properties seemed to be changed thereby. The views of Faraday have now been wholly accepted; but all careful work has its value, and even in those days Tyndall was able by his discoveries of the effects of pressure to make a material advance in the geological interpretation of the planes of cleavage in the earth's strata. Quite recently the application of X-ray methods to the study of the crystalline structure of substances makes it possible to offer a more complete explanation of Tyndall's results. The effects of pressure are to rearrange the minute crystals which most ordinary substances contain; and so Tyndall's results form part, not so much of the branch of science for which they were intended, as for that which deals with the effects of stresses of all kinds in altering the internal arrangement and the properties of materials.

MR. E. BRUNETTI recently presented to the Department of Entomology of the British Museum (Natural History) a collection of some 60,000 specimens of Diptera (two-winged flies) especially rich in Indian and North American material. The collection is the result, in part, of the entomological collecting done by Mr. Brunetti during the last forty years. The same Department has also received, under the terms of the will of the late Lieut.-Col. F. R. Winn Sampson, an important collection of insects of the group Scolytidæ (bark-beetles). The collection consists of some 11,000 insects and 1400 microscopic preparations, and the bequest includes a selection of books and pamphlets, and two microscopes. Accessions to the Geological Department include three interesting fossils of flying reptiles: the long-tailed group is represented by a specimen from the Lias of Württemberg; the short-tailed pterodactyls by an excellently preserved wing-skeleton from the Lithographic Stone of Bavaria, and by a slab with several scattered bones of a small form from the Middle Purbeck beds of Swanage. This last was found and presented by Mr. S. L. Wood, who also gave the remains of a turtle carefully pieced together, and some unusually complete jaws and teeth of Anoodon, an ancient cloven-hoofed animal, all collected by him from the Hamstead beds of Yarmouth, Isle of Wight. The Lower Devonian slates of Bundenbach have yielded most interesting fossils beautifully preserved in pyrites. To the valuable series already in the Museum, some new forms of starfishes, crinoids, and trilobites have been added. An important purchase agreed to was a collection of Ammonites, mostly preserved in pyrites, from various openings, now closed, in rocks of Bavaria and Württemberg corresponding to the Kellaways rock of Britain. There was also laid before the trustees a plaster reproduction of the most complete nest of dinosaur eggs found by the American Expedition in Mongolia; this has just been received from the American Museum of Natural History.

THE purchase has been approved for the Department of Minerals of the British Museum (Natural History) of a 9-kilogram mass of meteoric iron from Chile, probably belonging to the La Primitiva fall, remarkable for the large inclusions of the phosphide of iron and nickel, schreibersite; also specimens of twelve meteorites not hitherto represented in the collection; and a cast of the wonderful 688-kilogram ring-shaped meteoric iron of Tucson, Arizona. An interesting book purchased for the Museum Library is the very rare first edition of an account by Linnæus of his scientific expedition through the Swedish province of Skånen in 1749. This edition contained an expression of approval of the burning up of the top-soil, a custom of the inhabitants of Småland, and a practice to which Baron C. Hårleman, the patron of Linnæus, was strongly opposed. Hårleman had paid the expenses of the expedition, and he caused the withdrawal of the first edition of this work and the publication of a second without the offending comment.

MR. W. G. LOBJOIT, Controller of Horticulture at the Ministry of Agriculture, is retiring from that honorary post, and Mr. H. V. Taylor has been appointed Horticultural Commissioner of the Ministry and chairman of the Horticultural Advisory Council.

AT the meeting of the London Mathematical Society, at 5 o'clock on Thursday, Feb. 10, at the Royal Astronomical Society, a lecture entitled "Some Problems of Terrestrial Magnetism" is to be delivered by Prof. S. Chapman. Members of other scientific societies are invited to be present.

AT its meeting in Philadelphia in December last, the Botanical Society of America elected Prof. Harley H. Bartlett, of the University of Michigan, as president, and Prof. Arthur J. Eames, of Cornell University, as secretary. The following were elected corresponding members: Prof. Erwin Baur, of the Agricultural High School, Berlin; Prof. Robert Chodat, of the University of Geneva; Dr. L. Cockayne, of New Zealand; Prof. V. Grégoire, of the University of Louvain; and Prof. W. Johannsen, of the University of Copenhagen.

AT the monthly general meeting of the Zoological Society of London held recently, it was reported that the number of visitors to the Society's Gardens during the past year was 1,937,935, the receipts for admission amounting to £61,325, an increase of £2728 as compared with the figures for 1925. The numbers of visitors to the Aquarium during the past year was 436,327, the receipts for admission amounting to £17,242, an increase of £483 as compared with last year.

THE council of the Institution of Electrical Engineers has made the sixth award of the Faraday Medal to Prof. Elihu Thomson, of Boston, U.S.A., honorary member of the Institution, who is well known as one of the pioneers in the development of electrical engineering. It will be recalled that the Faraday medal is awarded by the council of the Institution not more frequently than once a year either for notable scientific or industrial achievement in electrical engineering or for conspicuous service rendered to the advancement of electrical science, without restriction as regards nationality, country of residence, or membership of the Institution.

DR. THOMAS NELSON records in the *Lancet* for Jan. 1 (p. 16) the after-results of the treatment of ten cases of tuberculosis by Mr. Spahlinger's methods in a London hospital. The cases were selected and treated by the late Dr. Latham about twelve years ago, and comprised one case of lupus, one case of spinal tuberculosis, and eight cases of pulmonary tuberculosis. The spinal case and one of the pulmonary cases cannot now be traced. The lupus case is still alive, but all the remaining seven pulmonary cases are dead—six of them within three years of the commencement of treatment.

A SLIGHT earth tremor was recorded at the Royal Observatory, Edinburgh, between 5.20 A.M. and 5.30 A.M. on Jan. 24. A message from Nairn to the Air Ministry also reported a slight earthquake at about 5.20 A.M., and records of the shock were obtained at Kew and Plymouth. The Kew record indicated a distance of about 500 miles for the centre of disturbance, but the disturbance was of less intensity than the Herefordshire or Jersey shocks of last year. Messages from correspondents of the *Times* in various parts of Scotland state that earth tremors were felt in the Orkneys, Deeside, Perthshire, and Fifeshire.

Notices have been issued of the offer of three Beit Fellowships for Scientific Research in July next. These fellowships are tenable at the Imperial College of Science and Technology, and will probably be awarded for two years. Candidates must be graduates of a university of the British Empire, of European descent, and less than twenty-five years of age. The annual value of each fellowship is £250. Application forms must be returned to the Rector, Imperial College of Science and Technology, South Kensington, London, S.W.7, by April 19 next.

The Government of the Province of Buenos Aires, Argentina, has just distributed vol. 5 of the collected works of the late palæontologist, Florentino Ameghino, dated 1916. The volume consists of papers, chiefly on fossil mammals, published between November 1884 and May 1889, but unfortunately the original place of publication is usually omitted. A general account of the mammal-bearing deposits of Monte Hermoso is reprinted from the Buenos Aires newspaper, *La Nación*, and there is an interesting address on the "Phylogenetic Evolution of Mammals," which was given in 1889 to the Argentine Geographical Institute.

At the first meeting of the eightieth academic year of the Pontifical Academy of the Nuovi Lincei, held in the premises of the Academy in the grounds of the Vatican and attended by his Holiness the Pope, Cardinals Merry del Val, Maffi, Vannutelli, and Ehrle, the two secretaries of the Academy, Profs. De Sanctis and Martinelli, and a number of members and others, the inaugural lecture by the president, Prof. Gianfranceschi, was followed by several papers on scientific subjects. At the conclusion of the session the secretary made preliminary announcements concerning the arrangements for the year and for the commemoration this year of the Volta centenary.

The sixth annual report of the Industrial Fatigue Research Board contains details of the organisation, investigations, and researches for the year ending December 31, 1925, followed by an analysis of the work published by the Board up to date. The various reports issued during the last six years have been analysed and all the evidence relating to a particular problem collected into one section. The first section deals with the scope and methods of investigations, the second with hours of labour in various industries, the third with atmospheric conditions and lighting, the fourth with methods of work, and the fifth with miscellaneous points such as individual differences, learning and practice, human and mechanical factors in production. It is a very useful compilation, and should prove a valuable guide to present-day research in industrial problems.

The trans-Atlantic telephone service to towns outside London and to several of the American States was inaugurated on Saturday, Jan. 22, by the exchange of messages between the vice-chancellor of the University of Cambridge and the president of Harvard University, Cambridge, Mass. Mr. A. L. Lowell, of Harvard, spoke first; the Rev. G. A. Weekes, who replied from the Master's Lodge in Sidney Sussex College, recalled the fact that Harvard received its name from John Harvard, a student of Emmanuel College, Cambridge, nearly three hundred years ago. Sir Ernest Rutherford, and Dr. Peter Giles, Master of Emmanuel, also spoke to Mr. Lowell, while Mr. Moran, president of the Southern Atlantic Telephone Company, spoke from New Haven, Connecticut. The extended service now includes most towns within about 110 miles of London, and on the other side of the Atlantic the States of Maine, New Hampshire, Massachusetts, Vermont and Rhode Island, and Connecticut.

The January issue of the ***Marine Observer***, the monthly review of the Marine Division of the Meteorological Office, contains the first of a useful series of articles dealing with radio telegraphy and weather forecasting. The series previously appeared in the first volume of the ***Marine Observer***, when articles on weather forecasting that had formerly appeared on the monthly weather charts were replaced and extended. The first chapters deal with observation, scales, and the drafting of reports. The practical information it supplies should be of use to many besides sailors. There is now a total of 500 ships regularly contributing observations to the Meteorological Office. Many of these make daily reports to 'all ships,' and the others are invited to do so with the view of each ship-master being in a position to make his own weather chart and forecast.

The scientific staff of the Madras Government Museum "has had," says the Report for 1925-26, "to devote almost the whole of its time to investigations." Coins and bronzes have been catalogued, a guide to the flowering plants of Madras City and its immediate neighbourhood has been pushed forward, the littoral fauna of Krusadai Island has been surveyed, and the life-histories of local insects have been studied. This work has enriched the collections but has delayed the improvement of the exhibited series.

We have received the new edition of Messrs. C. Baker's (244 High Holborn, W.C.1) catalogue of microscopes and accessory apparatus. The B.L.M. series of microscope stands has been extended and includes mineralogical models, and the prices have been drastically reduced. A new $\frac{1}{6}$-in. oil immersion lens, N.A. 0·95, has been added to the series of objectives, which may replace the medium-power dry lens when oil-immersion high-power lenses are also being used, and is serviceable for dark ground illumination. A new series of eye-pieces has been computed by Lieut.-Col. Gifford, "Gifford ortho-chromatic," which are claimed to be an improvement both in field and in definition, the field being half as large again as with the ordinary Huyghenian type.

ANOTHER volume of "Alumni Cantabrigienses," compiled by the late J. Venn and J. A. Venn, is announced by the Cambridge University Press. It will complete the first half of the work and bring the biographical record of all known Cambridge men down to the year 1751.

MESSRS. Longmans and Co., Ltd., announce for early publication "Flame and Combustion in Gases," by Prof. W. A. Bone and Dr. D. T. A. Townend. The book will review the results of modern research and the present state of science regarding gaseous combustion and explosions. It will consist of five sections, dealing respectively with the principal discoveries from the time of Boyle to the end of the Bunsen era (1660–1880); ignition phenomena, flame propagation through explosive mixtures, detonation flame structure and temperatures; pressure development during gaseous explosions in closed vessels; the mechanism of combustion; and catalytic or surface combustion.

NOTICE is given that applications for the Government grant for scientific investigations for the present year must be received by, at latest, March 31, at the offices of the Royal Society, Burlington House, Piccadilly, W.1. The applications must be upon a printed form obtainable from the Clerk to the Government Grant Committee, c/o the Royal Society.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A demonstrator in bacteriology at University College Hospital Medical School—Prof. A. E. Boycott, University College Hospital Medical School, University Street, W.C.1 (Feb. 7). An assistant chemist under the Northern Coke Research Committee—Prof. Briscoe, Armstrong College, Newcastle-upon-Tyne (Feb. 7). A male medical inspector of factories—The Industrial Division, Home Office, Whitehall, S.W.1 (Feb. 21). A senior lecturer in anatomy in the University of the Witwatersrand, Johannesburg—The Secretary, Office of the High Commissioner for the Union of South Africa, Trafalgar Square, W.C.2 (Feb. 28). The Stevenson lectureship in citizenship in the University of Glasgow—The Secretary, University Court, The University, Glasgow (Feb. 28). A lecturer and demonstrator in organic chemistry in the University of Sydney—The Agent-General for New South Wales, Australia House, Strand, W.C.2 (Feb. 28). An assistant Government analyst in Nigeria—The Private Secretary (Appointments), Colonial Office, 38 Old Queen Street, S.W.1 (Feb. 28). A Director of Antiquities in Palestine—The Under-Secretary of State for the Colonies, Colonial Office, Downing Street, S.W.1 (March 14). A helminthologist at the Imperial Institute of Veterinary Research, Muktesar, P.O. Ritani, U.P., India—The Director, Imperial Institute of Veterinary Research, Muktesar, P.O. Ritani, U.P., India (March 15).

ERRATUM.—In NATURE of Jan. 22, p. 114, col. 2, line 20 ("The Life of a Nilotic Tribe"), for "effect" read "affect."

Our Astronomical Column.

COMETS.—Mr. H. E. Wood, of Johannesburg, has telegraphed the following parabolic orbit of the new comet 1927 *a* discovered by Mr. T. B. Blathwayt.

$$T = 1927 \text{ Feb. } 12{\cdot}720 \text{ U.T.}$$

$$\left.\begin{aligned} \omega &= 228^\circ\ 52' \\ \Omega &= 18\ \ 40 \\ i &= 90\ \ 31 \end{aligned}\right\} 1927{\cdot}0$$

$$\log q = 0{\cdot}02522$$

An ephemeris deduced from these elements shows that the comet is unlikely to be seen in Great Britain, for it will remain below the horizon until April, and after that will only be above it in a bright sky. Its track lies through Scorpio, Ara, Telescopium, Pavo, Indus, Toucan, Phœnix, Fornax, Eridanus. It is nearest to the earth, 106 million miles, in mid-February. It should then be a conspicuous telescopic object for southern observers.

The Comas Sola object of Jan. 10 is probably a minor planet. Its approximate position on Jan. 29 will be R.A. $7^h\ 51^m$, S. Decl. 3° 14′. There is not yet sufficient material to hand to deduce the orbit.

A NEW REFLECTING TELESCOPE FOR EDINBURGH.—An article in the *Scotsman* of Jan. 11 contains the welcome announcement that the Observatory at Blackford Hill, Edinburgh, is shortly to obtain a large reflecting telescope of Cassegrain type, together with a spectrograph. The exact dimensions are not stated, but as it will be "at least as great as any other in this country," its minimum aperture may be presumed to be 30 inches. The proposed field of work is stellar photometry and spectroscopy. The useful work that has been accomplished in these fields in recent years at Edinburgh gives rise to the hope of very important results being obtained when the new instrument is in working order. The article also gives an interesting sketch of the history of the Observatory, which started on Calton Hill about 1818, and was moved to its present site in 1889 as a result of the benevolence of the late Lord Crawford, who offered his valuable collection of instruments and books on condition that the State provided proper buildings and maintenance for them. The offer was accepted and the new department placed under the Scottish Office.

A LARGE SUNSPOT.—A large single sunspot which was seen with the naked eye was on the sun's central meridian on Jan. 19 and continued on the disc until Jan. 25. This is the third spot or group of spots large enough to be seen this year without telescopic aid. Other particulars are as follows:

No.	Date on Disc.	Central Meridian Passage.	Latitude.	Area.
3	Jan. 13-25	Jan. 19·3	25° N.	1/1100 of sun's hemisphere.

A number of other spots across the sun's disc and patches of bright faculæ at the east and west limbs have been located with ease in small refracting telescopes 2 in. or 3 in. in aperture.

Research Items.

Gypsy Marriage Customs in Eastern Rumelia.—In the course of a correspondence on the language and conditions of the gypsies of Eastern Rumelia which passed between Dr. A. G. Paspati and Smart and Crofton in 1879, when the first named was in Constantinople, some interesting details were given of gypsy betrothal and marriage customs. In one letter of the series, which is published in Part 3, vol. 5 of the *Journal of the Gypsy Lore Society*, it is stated that the friends, male and female, of the bridegroom go to his intended bride's residence and demand her of her father. If he consents, the bridegroom and his friends go again to the father's house the next day and each receives a present, generally a handkerchief. The bride and bridegroom are then left alone while the party adjourns to an adjacent wine-shop, where they remain until evening. The bride and bridegroom dine together, drinking out of the same wooden bottle as a sign of love. After dinner the bridegroom leaves and the betrothal is considered valid. On the Friday before the wedding, a friend of the bridegroom goes with a wooden bottle to the bride, offering the groom's congratulations, and then with a donkey goes to the forest to cut wood for the ceremony. In the evening of the same day paste is kneaded for a cake to be baked and eaten on the wedding day. On the following day relatives of the groom carry the dowry to the bride. On the Sunday after the wedding the transparent red veil worn by the bride is taken off her face by the bridegroom's man by means of two slender vine sticks and laid on a rose-bush. He then carries two buckets of water on his shoulders taken from any fountain, and these the bride oversets thrice. The fourth time she follows him to the house of the bridegroom, kissing the hands of all passers-by.

A Crystal Mask from Tibet.—Mr. H. C. Beasley has published in *Man* for January an illustration of a remarkable crystal mask from Tibet. The mask is that of the goddess Palden Lhamo, one of the Eight Terribles, as is shown by a third eye in the middle of the forehead. The body of her face is worked up from a lump of rock crystal, the features are applied in gilt bronze, and the teeth are probably human, while the eyes are of ivory. It is said that the mask was used to attract evil demons, who were then dealt with by the officiating lama. Palden Lhamo corresponds to Kali of Indian mythology, and in Japan appears as a goblin under the name Mitsume. The Chinese god of disease Yü-yüen, recognisable by his long teeth, also has a third eye, and is probably derived from Palden Lhamo. She was also believed by the Tibetans to have been reincarnated in Queen Victoria. As one of the Eight Terribles, Palden Lhamo rides a chestnut mule, the offspring of a winged mare, and the gift of the goddess of the sea. She carries a string of skulls, and she feeds on corpses given her by the goblins who haunt graveyards, while her scanty garment is a girdle made of the skin of a recently flayed man. She is often shown drinking blood from a cup formed of a human skull.

Cocaine.—Prof. E. Poulsson contributes an article to the *World's Health* for December last (which appears in a new and more attractive cover than formerly) on the properties, use, and abuse of cocaine. The coca plant, coca chewing, and the properties of cocaine as an anæsthetic are described. The effects of cocaine upon the drug addicted are then summarised. These consist of a first stage of well-being or happiness, followed by a condition of restlessness and anxiety in which self-control may be lost. Continual snuffing of the drug causes nasal catarrh and ulceration of the nasal septum. An extremely characteristic effect is an intense pricking and creeping sensation in the skin, so that the habitué has the impression that it harbours worms or lice, and seeks to get rid of these by digging with his nails or the point of an instrument, so that the body may become covered with sores and ulcers. This form of drug abuse is very widespread, but the author considers that it will be more easy to combat than the use of opium and its products. Coca plantations are of comparatively recent origin and are far from possessing the economic importance of opium plantations. It is possible also to prepare synthetically drugs which possess the paralysing power of cocaine on the sensory nerves but have little or no effect on the brain. The more these are used, the less will become the medical need for cocaine itself.

Protection of the Great Skua.—Few birds have so restricted a range as the great skua, which in Britain formerly nested only in the Shetland Isles. Its present position is discussed in the *Scottish Naturalist* (1926, p. 169). It is shown that as a result of protection, first because it kept away the sea-eagle, and more recently under the Wild Birds Protection Acts, the great skua has extended its breeding range to several new areas. It is suggested that protection has now gone far enough, and that some restraint might well be placed on the further multiplication in certain areas of this robber and pirate. Its spread in one locality is shown to have been responsible for the complete disappearance there of black-headed gulls, arctic terns, red-throated diver, kittiwakes, and whimbrel, and even the strong herring gulls and lesser black-backed gulls have been reduced to a few pairs on ground which they formerly dominated. Strange to say, the only bird which seems to hold its own in face of the aggression of these great skuas is the common snipe.

The Warble-fly in Denmark.—Denmark is pre-eminently a cattle country, and on this account the damage done by the warble-fly had in 1903 reached the immense sum of £275,000. The matter had become so serious that the legislature took up the question, and in March 1923 passed a first law compelling stock-holders to rid their cattle of warble maggots, or failing such action to submit to the destruction of the pests by representatives of the parish councils at the owners' expense. An account of the legislation and its effects, by Harald Faber, Agricultural Commissioner to the Danish Government, appears in the *Journal of the Ministry of Agriculture* (Jan. 1927, p. 905). The results are striking. Of the 793,250 cattle herds in Denmark, 124,893 were freed from maggots in 1923; in 1924 178,044 herds were examined by authorised inspectors, and in 29·6 per cent. of these maggots were found and exterminated. The policy of the Government has been very satisfactorily reflected in the condition of Danish hides. Before the first law was passed in 1923 (it has been continued by subsequent enactments) the ratio of hides damaged by maggots in 1922 was 20 per cent.; in 1923, after a partial application of the law, damaged hides represented 15 per cent.; in 1924, with the law in full force, the number had fallen to 4·5 per cent., and in 1925 it was 4 per cent. The monetary saving has naturally been very considerable.

Small Holdings and Forestry.—Several of the papers read before the subsection of Forestry at the Oxford meeting of the British Association last year are reprinted in the half-yearly issue (Oct.) of the *Transactions of the Royal Scottish Arboricultural Society*. Perhaps the most important of these is the presidential address by Lord Clinton, entitled "Small Holdings in Relation to State Forest Policy." Much of the ground covered is well known to the scientific forester, especially on the Continent of Europe. It is satisfactory to British foresters to recognise that this aspect of a forest policy is now beginning to become appreciated in Great Britain. It is, in fact, the recognition of the absolute dependence of the forest for the bulk of its labour on some system of small agricultural holdings which afford a certain amount of occupation to the agriculturist at certain seasons of the year, full-time employment being obtainable at other seasons in the forest. Under the scheme adopted by the Forestry Commission, holdings are limited to 10 acres, and 150 days' work in the forest is guaranteed, but more may be granted. The advantages on both sides are obvious. The smallholder, cultivating a small area of land and with a small herd of stock for which grazing at specified times may be available, finds his main occupation in the forest. The State, outside the comparatively small full-time staff it is possible to employ in the management of forest areas, has at hand a labour supply which becomes increasingly skilled in forest work. Finally, the country acquires a settled, contented, and hardy community settled on the land. Small holdings, from the purely agricultural development point of view, are still a doubtful policy to follow. From the forestry viewpoint their successful inauguration in Britain is essential to the future progress of the afforestation work.

Russian Work on Microbiology.—The Bureau of Agricultural Microbiology of the State Institute of Experimental Agronomy at Leningrad, which is under the directorship of Prof. S. P. Kostychev, has commenced the publication of a *Bulletin*. The first volume has recently appeared, and it contains an interesting series of papers on biodynamics of soils, comprising results of extensive studies of the bacterial population of various soils and its chemical activities. Other papers include a study of the chemical conditions of fixation of atmospheric oxygen by *Azotobacter agili* (Kostychev a.o.); results of a detailed research in the symbiosis of various bacilli of milk (Ulrich), and two papers on the bacteriological method of control of rodents. Unfortunately, none of the papers is provided with a summary in a western European language, and this will restrict their usefulness to scientific workers of other countries.

Local Coast Submergence.—An example of local and relatively rapid submergence of the coast of Galveston Bay is described by Prof. D. W. Johnson and Mr. W. E. Pratt in the *Geographical Journal* for January. In 1917 an oil-field was started near the mouth of Goose Creek, not far from Houston, Texas. Since then, several million barrels of oil have been taken from the field with the result that the Gaillard peninsula, near the centre, and adjacent low coastal areas, have become submerged. In an area two miles and a half long by one mile and a half wide the maximum subsidence is now more than three feet. The ground involved consists of recent sands and clays only slightly more compacted than sea-bottom muds, and the oil is extracted mainly from depths between 1000 ft. and 4000 ft. Prof. Johnson is convinced that the subsidence is purely local and has nothing to do with any general sinking of the gulf coasts. Moreover, its area corresponds with the area of extraction, it is bordered by earth fractures, and it sinks steadily as extraction continues. Prof. Johnson cites this case as a rare, if not unique, example of subsidence of the earth's coast following the exploitation of an oil-field.

Exploration of the Russian North.—The Institute for the Scientific Exploration of the North at Leningrad (*Sjezdowskaja* ul., No. 1-3) is publishing a series of its transactions in separate parts, each part containing either one complete paper, or several papers dealing with the same subject. So far, in the interval 1920–1927, thirty-four parts have appeared, dealing with widely varying aspects of the country under exploration. More numerous than any others are the reports on geography, geology, and mineral resources, which include accounts by A. E. Fersman on the tundras of Kola Island (Part 29), and on the Chibina Range of the same island (Part 16); by A. A. Grigoriev on the geology and geological history of the Bolshezemelsk tundra (Part 22); by A. A. Tchernoff, D. I. Stcherbanoff, D. Beliankin, and others, on the mineral deposits of various regions of northern Russia (Parts 10, 18, 20, 24, 35); by V. A. Lindholm on the post-Pliocene mollusca from Murman (Part 12), etc. Another valuable set of papers deals with fish and fisheries of north Russian seas as well as of the Petchora River. These papers include keys to the sea-fishes by Prof. N. M. Knipovitch (Parts 27 and 31); an exhaustive study of the White Sea herring by A. J. Rabinerson (Part 25); a description of fishes and fisheries of the Petchora River by Prof. W. K. Soldatoff (Part 17), etc. Part 19 contains studies of hydrology, currents, and fauna of the Barents Sea by Prof K. M. Derjugin (including descriptions of some new species from various orders). Ornithologists will find an interesting account on the nesting colonies ("loomeries") of *Uria troille* L. in Novaya Zemlya, in Part 26, by G. P. Gorbunoff. Several papers deal with the economic aspects of the country, these comprising papers by N. Volens on the industries, and especially the agriculture, of the Petchora region (Part 21) and of the Murman coast (Part 28), while S. V. Kerzelli deals specially with reindeer breeding (Part 13). One paper, by V. G. Bogoraz, is devoted to the problems of ethnography in northern Russia.

Tar-distillate Sprays.—The Ministry of Agriculture and Fisheries has issued (Dec. 1926) information based on experimental evidence as to the best use of tar-distillate sprays for fruit trees. These new 'proprietary' washes, which are rapidly superseding the caustic sprays, are made by emulsifying a certain part of the tar-distillate. Carbokrimp, Chafers' No. 1 Winter Wash, Ialine Tar Oil Winter Wash, and Mortegg, applied in January at 7½-10 per cent. concentration, were found successful in controlling Rosy Apple aphis and Apple Sucker, while 6 per cent. solutions satisfactorily reduced both aphis and 'brown rot' on plums. Apple and plum trees may also be considerably freed from the caterpillars of the winter and tortrix moths, but these washes are ineffective in reducing apple scab and 'red spider'; if, however, this latter pest occurs on gooseberries, it can be successfully checked by the same sprays. In order to ensure success, the instructions issued must be carefully followed, especially as regards the time at which to carry out the operation. Spraying can only be done with safety when the buds are dormant, *e.g.* up to the end of January for plums, and somewhat later for apples. Further, the washes should not be applied before December, in order to ensure that the various pests have laid their eggs. Fine, but not frosty, weather is the most suitable. If the water of the district is very hard, an addition of 1 lb.-2 lb. powdered size or glue per 40 gallons is advised. An annual treatment is recommended, as the effect may be more marked in the year following the season of application. Besides the destruction of insect pests, a luxuriance of foliage produced in the succeeding year is noticeable, although any green leaves in actual contact with the spray will be liable to scorch.

THE MERCURY-ARC POWER RECTIFIER.—Great progress has been made recently in improving the mercury-arc power rectifier for converting alternating current into direct current. It is now very widely used. In the December issue of the *Review* published by the Brown Boveri Co. of Baden, in Switzerland, we learn that one of their rectifiers was tested at a direct current pressure of 8000 volts. It produced a pressure of 12,000 volts between the anodes of the device when the transformer was connected for three-phase working. No disturbance occurred when the rectifier was interrupted under a load of 900 kilowatts. This shows that the voltage limit has not yet been attained. The main difficulty that has to be overcome is to disperse by artificial means the heat produced in the rectifier, as it is a stationary piece of apparatus. In the same *Review*, Mr. Seitz writes a valuable paper on the methods employed for cooling rectifier sets. The methods generally employed are direct cooling by water, indirect cooling by water, and cooling by natural or forced draught. When a continuous water supply cannot be guaranteed, a water flow alarm is supplied so that serious trouble can be avoided. When the water is very hard or when it is impure, indirect water cooling is employed, a special pump being used to keep up the circulation. Natural draught is only used when the load is very small or intermittent and when the room temperature does not exceed 15° C., thus permitting a temperature rise of about 35° C. for the rectifier. For medium and large-sized rectifiers, forced draught is used, centrifugal fans being employed to cool pipes containing circulating water. For a direct current of 1000 amperes and a mean temperature rise of 25° C., the power expended in the fan and circulating pump does not exceed one horse-power.

ESTIMATION OF PHOSPHATES IN CALCAREOUS SILOS.—In the Chemical Series of the *Memoirs of the Department of Agriculture*, India, 8, No. 6, S. Das shows that in the case of highly calcareous soils, Dyer's citric acid method for the estimation of available phosphoric acid is unsuitable, and if the calcium carbonate content of the soil ranges from 1 to 7 per cent., is equally unsatisfactory for potash determinations. After experimenting with various salt solutions, a new and trustworthy method for use with such soils is described. A 1 per cent. potassium carbonate solution is employed for the soil extraction, the proportion of soil to solvent being as 1 : 10, and after shaking for 24 hours at laboratory temperature, the dissolved P_2O_5 in the extract is estimated by the ammonium molybdate method. The underlying principle of the action of 1 per cent. potassium carbonate solution on calcareous soils is twofold; a reaction takes place with any dicalcic or such other phosphates present, with the production of insoluble tricalcium or other phosphates and of soluble potassium phosphate; and, further, any phosphorus in organic combination in humus is also dissolved.

MARINE STEAM TURBINE PROGRESS.—Marine engineering practice sometimes leads, sometimes follows, land practice. In power stations ashore, advances have been made in the matter of higher steam pressures, the highest on record being 1200 lb. per square inch. The use of steam at 300 lb. to 400 lb. per square inch is fairly common, and considerable economy has been obtained by the utilisation of such pressures. Attempts are now being made to adopt higher pressures in ships, and an account of the latest advance is contained in a paper on "Progress in Economy of Turbine Machinery on Land and Sea," by Sir Charles Parsons, Mr. R. J. Walker, and Mr. Stanley Cook, recently read to the North-East Coast Institution of Engineers and Shipbuilders. Accompanying the discussion of the value of higher pressures, superheating, and other features of modern practice, are some historical notes and tables giving important details of the various turbine installations, both ashore and afloat, which have in turn created records, and at the end of the paper there is an account of the notable vessel, *King George V.*, launched on the Clyde last summer. Though Loftus Perkins more than forty years ago crossed the Atlantic in the *Anthracite*, using steam at 350 lb. per square inch pressure, general marine practice hitherto has demanded no more than 200 lb. to 250 lb. per square inch pressure in the boilers. In the *King George V.*, however, a vessel of 3500 horse-power, the Parsons-geared turbines are supplied with steam at 550 lb. per square inch superheated to 750° F., the steam being generated in Yarrow boilers. After the builder's trials the *King George V.* was placed on service on the Clyde and ran for three weeks to the end of the season. Consumption trials were then carried out, when with coal having a gross calorific value of 13,880 B.T.U., the fuel consumed worked out at 1·1 lb. per shaft horse-power per hour, thus easily beating all previous records hitherto obtained at sea.

ELECTRIC TRACTION.—In the *Journal of the Institution of Electrical Engineers* for January, F. Lydall gives a review of the progress of electric traction throughout the world which puts the progress made in Great Britain in a much more favourable light than has been generally accepted. Broadly speaking, we can divide railway electrification schemes into suburban and main line schemes. In Great Britain electrification is almost wholly confined to suburban schemes. The Southern Railway utilises it largely. It recently extended the electrification of the south-western section by the addition of about 70 miles to the length of track equipped, and the conversion of about 250 miles of suburban lines on the south-eastern section. The 127 miles of track on the Brighton section already equipped with overhead wires are being gradually converted to the third rail system. Considerable additions are also being made to the electrified portion of the line. The Southern Railway will soon have 854 miles of track electrified on the same third rail system. In France suburban electrification is much less prominent, the principal schemes being the main line electrifications on the Paris-Orléans and the Midi railways. In Switzerland electrification of the main lines has been carried out on a large scale. In Italy electrification has been in progress for the past twenty-five years, and the mileage of track equipped exceeds 600. In Germany the electrification of railways, especially in Silesia and Bavaria, is proceeding very rapidly. By the end of the year the electrified track will be about 700 miles. In Austria the progress has not been so rapid, owing to financial stringency. It is, however, in the United States that much the greatest progess has been made. As electric operation can provide facilities greatly superior to those obtainable from steam operation in respect of schedule speed, and volume of traffic, it is natural that all the great cities in the eastern states have extensive urban and suburban services. In no less than fifteen cities of the United States steps have been taken towards the elimination of smoke from locomotives by electrification or other means.

Researches on Sex-Change in the European Oyster.

THE fundamental fact about the breeding of the edible oyster is that the manifestations of this function may vary individually and in gross from season to season in a given locality, and, in general, differ also in different localities roughly according to the degree of warmth of their environment.

A modern research on the breeding of this mollusc should therefore include (*a*) adequate records of the environmental conditions, of which—if the animals are living under healthy conditions—temperature variation may be postulated as one of the most important; (*b*) a significant amount of healthy material the age of which has been unimpeachably determined by experimental methods; and (*c*) experimental observations on the successive sex-conditions during one or more years of a significant number of individuals which are living under conditions as nearly natural as it is possible to attain. The modern standard of research is very high, and it is impossible for any one worker to attain it on this problem without lengthy and large-scale operations.

During late years considerable attention has been again given by workers in various parts of Europe to an inquiry on the sex-conditions and sex-changes of the European oyster (*O. edulis*). In 1925, R. Spärck, a young Danish biologist, published a valuable paper[1] on the subject, giving the results of several years' work (1919 to 1923) on oysters obtained from the Limfjord. In a useful review of the literature on this subject, Spärck clearly shows the confusion which existed even down to recent years with regard to our ideas of sex-phenomena in one of the commonest economic molluscs. The difference in opinion which existed amongst well-accredited workers in the nineteenth century is well brought out by Spärck, who finds in the literature that oysters are described variously as comprising hermaphrodite, male, and female individuals (Davaine), all potentially hermaphrodite (Lacaze-Duthiers), all mainly male or female (Mobius and Hoek), that oysters are simply protandric hermaphrodites (a popular conception even in recent years); that they do not spawn until three to four years of age; that they do spawn at one year; that sex-change does occur (Davaine) or does not (Lacaze-Duthiers); that there are always 100 times more males than females (Davaine); that figures given show that there is a higher porportion of females than Davaine states (Mobius and Hoek). From these details there can be no doubt that the earlier workers had found out or surmised most of the facts, but the difficulty at the present time is to sort them out and place them in their true order; hence the need for modern critical research.

The confusion in the past has been largely due to the failure of workers to produce experimental facts, and also to the failure to differentiate fact from opinion; and indeed, until more biological work is stated in the order, experiment, observations, inference, the cycles of words used in the oyster literature of the nineteenth century are likely to be repeated in the twentieth.

In Spärck's work the difficult subject of inshore temperature variation is accounted for with a daily record at 8 A.M. of the water at Oddesund, at a position not precisely stated and the daily temperature-variation of which is not given, nor its relations to the variation on the beds whence oysters were taken for examination. Charts of the Limfjord show the 3-fathom line to lie close to the shore at Oddesund itself, but about half a mile to a mile off shore in other parts. It is well known that the temperature of shallow water on such an extensive foreshore will follow that of the air closely, and in summer the mean temperature will rise to a varying degree above the mean temperature of the air (compare when plotted together, the author's Fig. 15, which is apparently *mean* air, and Fig. 11), unless replaced by tidal water sweeping in directly from the open sea. It might easily happen, therefore, that while the temperature at 8 A.M. at Oddesund on a given day were 14° C., at another position a mile away and half a mile from the shore the temperature might easily at some period of the day be 16° C. or more (compare the author's statements on pp. 41 and 21). It is not sufficient to assume that the surface readings at Oddesund at 8 A.M. in the morning will give a correct picture of the variation in temperature over the oyster beds; the assumption is unjustifiable, but if it were justified the proof should be given. The author's treatment of temperature records from other regions is mostly unconvincing in a similar manner. The oyster biologist should indeed command a good general and practical knowledge of hydrography, and ought to make constant use of thermometric instruments on the beds, or at least to have one up his sleeve.

Those conclusions which Spärck bases on the Oddesund temperature records—for example, that there is no fixed temperature limit below which oysters will not spawn—cannot, therefore, be regarded as substantiated by adequate observational data. His definition of the oyster as a *protandric alternating hermaphrodite* is, however, supported by an increasing body of evidence, and may stand the test of time. His observations on seasonal sex-condition lead him to a conclusion similar to that formerly propounded—apparently unknown to the author—by B. Helland Hansen, namely, that complete egg-development is a product of time and temperature (calories). There will no doubt be sufficient data accumulated in the near future to settle this interesting problem.

It is also stated that egg-development ceases at 10° to 12° C.; that at (sustained summer periods of) temperature of 20° to 22° C. each individual may become female once a year; or only every three or four years (at sustained summer periods) at 14° to 16° C.; but the two latter at least of these statements are debatably inferential and not founded on experimental or demonstrated data.

Three valuable cases of sex-change from male to female were observed experimentally, but the number of failures to observe change is not noted, nor are the sex-changes themselves critically discussed. An observation is made by Spärck, that in regions of low salinity (and relatively high temperature) in the Limfjord, oysters appear to grow much more slowly than in regions of high salinity and relatively low temperature (p. 21); one suspects that the author is arguing in a circle from size at breeding to age and age to size, but if experimental data could be obtained to verify these statements, an important addition would be made to our knowledge on shell growth. Besides interesting remarks on seasonal feeding, on greening, on enemies, and on the fluctuations in the local stock of oysters, Spärck discusses the general effect of external conditions on sex, and arrives at the conclusion that "an alteration in the surrounding conditions results in an alteration in the kind of sex."

J. H. Orton.

The Third Pan-Pacific Science Congress.

THE third Pan-Pacific Science Congress was held at Tokyo on Oct. 30–Nov. 11, 1926, under the auspices of the National Research Council of Japan and through the generosity of the Imperial Japanese Government. It must well have been one of the most remarkable scientific meetings ever held. The main objects of the Congress, like those of the first held in Honolulu in 1920, and of the second held in Australia in 1923, were (1) to initiate and promote co-operation in the study of scientific problems relating to the Pacific region, more especially those affecting the prosperity and well-being of the Pacific peoples; and (2) to promote a feeling of brotherhood and to strengthen the bonds of peace among Pacific peoples. It was laid down that all branches of physical and biological science formed proper subjects for discussion, provided that they bore upon some Pacific problem.

The Congress was attended by 150 delegates from countries outside Japan, and by 400 Japanese members. At the opening meeting, speeches of welcome were made by the Prince of Kan-in and by the Prime Minister of Japan. In addition to the general opening and final meetings, two joint meetings of all members of the Congress were held. At the first of these such papers were read as constituted a review of the present state of knowledge of the physical and biological oceanography of the Pacific, and at the second such papers as dealt with special plans for international co-operation. At five other sessions the different branches of science were grouped together so as to form two broad divisions, namely, the physical and the biological. At the remaining sessions simultaneous sectional meetings were held, there being sections for astronomy, meteorology and terrestrial magnetism, radio waves, geology, seismology, architecture, botany, zoology and fisheries, agriculture, geography, hygiene and medicine.

The object of the broad divisional meetings was an attempt to realise solidarity of feeling and action, and this attempt was eminently successful. At the meetings of the physical division the papers were grouped under the following headings: Meteorological and time-service by radio transmission and causes which give rise to its disturbance; form of the geoid as deduced from geodetic observations, measurements of gravity and plumb-line deviations; suitable projections for maps on different scales; crustal movements and geotectonics, earthquakes, crust-tides, and variation of mean sea-level; study of volcanoes in their various aspects; thermal springs; metallogenetic epochs and their bearing upon structural unity; distribution of rare elements.

At the meetings of the biological division the subjects were grouped under the following headings: Rational methods for the protection of useful aquatic animals and plants; genetics in relation to the improvement of important crops, more particularly rice, and of live stock; distribution of bonitos and tunnis and their ecological studies; distribution and life-history of freshwater eels; international co-operation in the investigations of pelagic fish eggs and larvæ; preservation of natural monuments; rational methods of storing cereals; scientific bases for plant quarantine.

In all, more than 430 papers were presented and briefly described, printed abstracts being provided in advance. The full text of the papers, when published, will be of enormous value.

At the final general meeting many resolutions were passed on the recommendation of divisions, sections, and special committees, and, in particular, rules were drawn up for the constitution of a permanent Pacific Science Association, the function of which will be to organise future congresses. An invitation from the delegation of the Netherlands East Indies to hold the next congress in Java in 1929 was accepted.

Before and after the Congress long excursions were made, covering the land from Hokkaido to Kyushu, while two days in the middle of the Congress were devoted to shorter excursions. In all, there were about twenty excursions, and practically all overseas delegates were shown the beauties and wonders of Nikko, Hakone, Kyoto, and Nara.

Throughout the Congress itself and during the excursions, all overseas delegates and their families were the guests of the Japanese. The extent of the hospitality was only equalled by the perfect organisation, and both were the wonder of all visitors. The president of the Congress was Prof. J. Sakurai, the vice-president Prof. A. Tanakadate, and the general secretaries Profs. N. Yamasaki and K. Matsubara. In consideration of the great importance of these congresses, from both the national and international viewpoints, the Japanese Government, upon the recommendation of the National Research Council, had made a grant to be used for defraying the expenses.

Social functions formed a prominent part of the whole proceedings. Three garden parties were given by members of the Imperial family, and others by the Minister for Foreign Affairs and Baron and Baroness Fujita. Dinners were given by the Prime Minister, the president of the Congress, and the Mayors of Tokyo, Kyoto, and Osaka, while luncheons were given by the presidents of the Imperial Academy and of the Pan-Pacific Association of Japan. Theatrical performances of distinctive Japanese type were provided by Baron and Baroness Mitsui, and by the directors of the Imperial Theatre, while there were entertainments at each of the mayoral dinners. In addition there was much hospitality and entertainment of a more sectional and private character. No delegate from overseas will ever forget the cordiality of the welcome received from all types of Japanese citizens. J. P.

Loutreuil Foundation of the Paris Academy of Sciences.

THE Paris Academy of Sciences received thirty-three applications for assistance under the Loutreuil Foundation, and has made the following grants:

(1) Establishments specially named by the founder. Muséum national d'histoire naturelle (15,000 francs), École nationale vétérinaire de Lyon (7000 francs), École nationale vétérinaire de Toulouse (7000 francs). These three grants are for the same purpose, to permit these establishments to complete the sets of foreign periodicals in their libraries which have been interrupted during and since the War.

Institut national agronomique. 3000 francs to Jean Guérillot, for the purchase of apparatus for carrying out researches on the action of radio-activity in plant biology.

(2) Establishments admitted for a year by the president.

Conservatoire national des arts et métiers. 15,000 francs to Léon Guillet for the installation of a radiospectrograph in the metallurgical laboratory. 2500 francs to Emilio Damour for the purchase of apparatus for the glass laboratory.

(3) Independent requests.

4000 francs to Charles Alluaud, as a contribution to a zoological expedition to Morocco.

6000 francs to Benjamin Baillaud, for the construction and installation, in the time signal department of the Paris Observatory, of a pendulum maintained by light rays and a photo-electric cell.

2500 francs to Jules Baillaud for carrying on experiments with the view of establishing a primary standard of light.

6000 francs to Henry Chabanier, for the purchase of apparatus for carrying out researches on nephritis, and particularly on the mechanism of oedema resulting from lesions of the kidneys.

3000 francs to Henri Chaumat for the construction of a new wattmeter with an arrangement permitting the determination of the angle of phase of a magnetic field and of the current producing it.

9000 francs to the Comité français de Géodésie et Géophysique (Section of Atmospheric and Telluric Electricity) as a contribution to the cost of the sixth expedition dealing with the new magnetic network of France.

3000 francs to Hipployte Janvier for his biological studies in the Chilian Hymenoptera.

2000 francs to Paul Nottin for the continuation of his researches on the saccharification of starch.

5000 francs to Jean Mascart for assuring the publication of documents concerning the study of the variable stars, centralised at the Lyons Observatory.

2000 francs to Paul Pallary for his researches on the fauna of Morocco and the extension of the glacial régime in the Moyen-Atlas and the upper basin of Oumer Rebia.

10,000 francs to Pierre Teilhard de Chardin as a contribution to a new palæontological expedition in China.

9000 francs to Jean Thibaud for extending his researches on the structure of the atom and the radiations of radio-active substances.

4000 francs to Henri Deslandres for the publication by the Meudon Observatory of synoptic charts of the upper solar atmosphere and the details characteristic of this layer.

2000 francs to Joseph Guillaume to assist him to continue, in his private observatory, the observations which he had pursued for thirty-three years at the Lyons Observatory.

6000 francs to the Comité de patronage de la faune coloniale française, for starting this important work.

6000 francs to the Faculté française de médecine de Beyrouth for contributing to the publication of the "Flore de Syrie."

University and Educational Intelligence.

Birmingham.—The subject of the Huxley Lecture to be delivered by Prof. Elliot Smith on Feb. 1 is "Science and Culture," the realisation of Huxley's ideals. The lecture will be open to all members and friends of the university.

Cambridge.—Through the University Association, a sum of £1025 has been bequeathed by the late Michael Emil Lange, of Christ's College, for the further endowment of the University.

Edinburgh.—The International Education Board of New York has given a sum of £74,000 as a contribution to the cost of the new Department of Zoology and in recognition of the work of Prof. J. H. Ashworth, professor of zoology in the University. The new Department will be at the King's Buildings, West Mains Road.

London.—The two following courses of free public lectures at University College are announced: "Reproduction," by Dr. A. S. Parkes (on Feb. 7, 14, 21, 28, Mar. 7 and 14), and "The Action of the Sense Organs," by Dr. E. D. Adrian (on Feb. 9, 16, and 23). The lecture hour in each case will be 5 o'clock.

Oxford.—Mr. A. G. Tansley, lecturer in botany in the University of Cambridge, has been appointed to succeed Sir Frederick Keeble as Sherardian professor of botany at Oxford. Mr. Tansley was president of Section K (Botany) of the British Association at the Liverpool meeting in 1923, and is the author of a number of papers and other works on plant ecology.

Five fellowships tenable for two years, each of the annual value of £200, will be awarded in 1927 to graduates of the University of Wales. Applications for the fellowships must be received before June 1, by the Registrar, University Registry, Cathays Park, Cardiff, from whom further information may be obtained.

The International Federation of University Women held its fourth conference at Amsterdam on July 28–Aug. 2, 1926. It has published a report (pp. 176, price 1*s.* 6*d.* post free, obtainable from the Secretary, 92 Victoria Street, London, S.W.1) containing much interesting information bearing on the various subjects discussed: international fellowships for research and travel, interchange of secondary school teachers, the problem of a language of international intercourse, the means of reconciling marriage with a professional career, and several others. The accounts given by ten distinguished members of the Dutch Federation of the work of university women in Holland and its colonies are of outstanding importance, indicating as they do, with considerable fullness, the place of university women in the national economy. Prominent among the sciences in which women have shown capacity for advanced work is biology. Of 245 women in Holland who have completed university studies in this branch of science, 45 are married and have no professional occupation, 129 are teaching, chiefly in secondary schools, and 41 are scientific workers in universities, including 21 in agricultural stations and 11 in museums, etc. Of 246 who have completed a medical course, 183 are practising doctors. Nearly half of them are married (59 to medical men) and 56 of these have full-time practices; 35 medical practitioners work in the Dutch East Indies, 19 holding government appointments. In pharmacy, women assistants (1698) largely outnumber the men (308), although there are only 217 fully qualified female pharmacists to 643 male. In dentistry there are 576 men to 132 women. In the Dutch colonies there are women physicians (35), dentists (22), chemists (10), biologists (9), doctors-in-law (9), teachers (16), and one theologian.

Calendar of Discovery and Invention.

January 30, 1826.—A great achievement was brought to a successful termination on Jan. 30, 1826, when Telford's famous suspension bridge over the Menai Straits was opened and the London mail-coach crossed to Anglesey. Hitherto the passage of the Straits by boat had often been difficult and dangerous. Among the most graceful of such structures, the bridge has a central span of 579 feet. Its main features are the sixteen chains formed of flat wrought iron bars 10 ft. long, 3½ in. wide, and 1 in. thick.

January 31, 1858.—In a decade which saw the Great Exhibition, the discovery of the first coal-tar colours, the invention of the Bessemer process, and the laying of the first Atlantic cable, there was no greater experiment than the building of a steamship to run between England and Australia carrying sufficient coal for the round trip. The *Great Eastern* was begun in 1854 and, after extraordinary difficulties, was launched in the Thames on Jan. 31, 1858. Though a commercial failure, she was a splendid specimen of naval architecture and a worthy monument to her designers, Scott Russell and Brunel.

January 31, 1895.—In a letter to NATURE in September 1892, Lord Rayleigh directed attention to a slight difference in the densities of nitrogen prepared from two different sources. This letter led to the collaboration of Lord Rayleigh and Sir William Ramsay. In April 1894, Ramsay wrote to his wife, "I am at work on nitrogen but not from the commercial point of view. . . . Nitrogen of air is heavier than nitrogen from ammonia in the ratio 251 to 250. That would correspond with the addition of some light gas to the heavy one, or of some heavy gas to the light one." In August 1894 he was able to say, "I have isolated the gas. Its density is 19·075." The new gas was named argon, and the full story of its discovery was told by Rayleigh and Ramsay at a special meeting of the Royal Society held on Jan. 31, 1895.

February 2, 1891.—In 1887, Lord Rayleigh pointed out how particles of silver might be deposited in layers half a wave-length of light apart. Four years later, on Feb. 2, 1891, before the Paris Academy of Sciences, Gabriel Lippmann explained the discovery of the process of colour photography by interference.

February 3, 1851.—The idea of using a swinging pendulum to demonstrate the rotation of the earth was due to Leon Foucault, who described his experiments to the Paris Academy of Sciences on Feb. 3, 1851. Some of his demonstrations were made in the Panthéon, but when, a year or two later, the Panthéon again became a church, the pendulum was shown in motion at the Champs de Mars.

February 4, 1812.—Preserved in the Deutsches Museum, Munich, is the apparatus by which Sömmering in 1809 sent signals by electricity. His attention had been attracted to the subject by the successful use of the semaphore during Napoleon's Austrian campaign. Commencing in 1809 with communicating between points 38 feet apart, on Feb. 4, 1812, he was able to send signals almost ⅔ of a mile.

February 5, 1870.—At the Academy of Music, Philadelphia, on Feb. 5, 1870, before an audience of more than 1500 people, Henry Heyl publicly exhibited on the screen a series of posed pictures showing the movements of a couple waltzing. The effect was obtained by placing photographs round the edge of a disc which was driven step by step in strict time with the music of the orchestra. This was the first public motion picture show, and the Academy has been popularly called "the birthplace of the movies."

E. C. S.

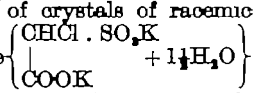
Societies and Academies.

LONDON.

Royal Society, Jan. 20.—J. Topping and S. Chapman: On the form and energy of crystalline sodium nitrate. The total potential energy has been found for a series of configurations of the ions of the crystal, by the addition of the potential energy due to the intrinsic repulsive forces between the various ions, to the electrostatic potential energy, which was calculated in a previous paper. The stable configurations of the crystal corresponding to a minimum value of this energy has been found for various values of the distance b between the N and O ions of an NO_3 group. The value of b suggested is about 0·96 Å.U., which is somewhat larger than the value of 0·72 Å.U. given in the former paper.

C. N. Hinshelwood: Quasi-unimolecular reactions—the decomposition of diethyl ether in the gaseous state. The decomposition of gaseous diethyl ether is a reaction which obeys the unimolecular law at high pressures, but becomes more nearly bimolecular at lower pressures. A sufficient amount of hydrogen completely stops the falling off in the unimolecular velocity constant at low pressures; helium and nitrogen have little or no influence, while the reaction products in considerable excess have a slight retarding influence. There are enough collisions to activate the molecules if the energy of activation is assumed to be distributed among about eight degrees of freedom. These and other 'quasi-unimolecular' reactions are most simply explained on Lindemann's theory.

W. G. Burgers: An X-ray investigation of optically anomalous crystals of racemic potassium chlorosulpho-acetate. In an investigation of crystals of racemic potassium chlorosulpho-acetate



$$\left\{\begin{matrix} CHCl\,.\,SO_3K \\ | \qquad\qquad + 1\tfrac{1}{2}H_2O \\ COOK \end{matrix}\right\}$$

by F. M. Jaeger, it was shown that these crystals exhibit an anomalous optical behaviour, and that variations occur in the angles between some of their faces. Investigation of the crystals by X-rays shows that the crystals are truly orthorhombic, and that the irregularities of their habit must be caused by a slight difference in orientation of successively crystallised layers. The optical anomalies may be due to strains in the crystals. The space-group of the crystals is Q_h^{14}, the underlying lattice Γ_0. The dimensions of the unit cell, which contains eight groups of the above formula, are $a=8{\cdot}58$ Å.U., $b=8{\cdot}60$ Å.U., $c=23{\cdot}76$ Å.U.

J. Topping: On the mutual potential energy of a plane network of doublets. The mutual potential energy of a set of coplanar doublets with their axes all perpendicular to the plane has been found at the net-points of (1) a square network, and (2) an equitriangular network. If the number of doublets per unit area be the same in both cases, the energy per unit area differs only by about 2 per cent. This result may be applied to a layer of polarised molecules on the surface of a fluid, so that a fairly definite estimate of the energy can be made for any probable mode of packing of the molecules.

D. Buchanan: Periodic orbits of the second genus near the straight-line equilibrium-points in the problem of three bodies. The particular problem considered pertains to periodic oscillations in the vicinity of the Lagrangian straight-line equilibrium-points, when the two finite bodies move in circles and the third body is infinitesimal. The first-genus orbits near these equilibrium-points were first obtained by Darwin. The orbits with which this paper is more particularly concerned are those of Class A of Moulton's 'Oscillating Satellite.' With respect to rotating axes, they have the shape of the figure 8, with the top and bottom of the 8 bent up from the page. They re-enter after one revolution. The second-genus orbits considered are in the neighbourhood of these figure-8 orbits, but re-enter only after many revolutions. The ratio of periods of orbits of the two genera is a function of distance between them at initial times.

L. F. Richardson: The deferred approach to the limit. This is an investigation of the validity of an arithmetical process, here called the 'h^2-extrapolation,' which has previously been used for solving differential and integral equations.

J. E. Lennard-Jones and **B. M. Dent**: Some theoretical determinations of the structure of carbonate crystals. Part 1. This paper provides data for the calculation of the potential energy of any crystal of the calcite type for which the forces between the constituent ions are known. Two crystals, namely, $MgCO_3$ and $CaCO_3$, are considered in detail, and theoretical determinations are made of the size and shape of the rhombohedral cells. In addition, the investigation determines an absolute value for the energy of these crystals is obtained. Part 2. A theoretical relation is obtained between the size of the rhombohedral cell of the carbonate crystals and the magnitude of the forces between the metallic and oxygen ions.

J. A. Gaunt: The first step in the approximate solution of differential equations by interpenetrating lattices.

J. W. McBain and **W. B. Lee**: Adhesives and adhesions: true chemical compounds as adhesives. Pure crystalline substances fully rival well-known adhesives in the strength of joint obtainable by them and may yield joints between optically polished metal surfaces the breaking strength of which may approach one ton per square inch. Pure liquids give results of a lower order of magnitude. In all cases the thinner the film, the stronger the joint. This rule holds for ordinary adhesives as well, provided that the film completely fills the space between the surfaces joined. There is direct parallelism between joint strength and the mechanical properties of the materials joined. Joint strength rises with tensile strength and elasticity, and falls with atomic volume and compressibility. Good lubricants with high spreading coefficients are poor adhesives. Joint strength is often much the same, whether tested in tension or in shear. Disorderly arrangement greatly enhances strength and joint strength.

W. L. Bragg: The structure of phenacite, Be_2SiO_4. The structure of phenacite, Be_2SiO_4, is examined, and an attempt made to find the positions of the silicon and oxygen atoms. The structure proposed resembles the simpler structure of the olivine group (Mg_2SiO_4, Fe_2SiO_4) in that its form may be explained as a packing together of oxygen atoms whose centres are 2·7 A.U. apart, with the atoms of metal and silicon between groups of oxygen atoms, but the arrangement is more complex. In phenacite, silicon atoms lie at the centre of tetrahedral groups, and similar positions are probably occupied by beryllium atoms. A rearrangement is achieved at the expense of slight increase in volume associated with each oxygen atom, when the structure is contrasted with such structures as $BeAl_2O_4$, where close-packing holds. The structure is determined by 21 parameters, 15 of which are measured.

P. A. M. Dirac: The physical interpretation of the quantum dynamics. To interpret physically calculations of quantum dynamics, a number of special assumptions are previously made; for example, that the elements of the matrix that represents the total polarisation determine the frequencies and intensities of the spectral lines, in analogy with the classical theory, or that the square of the amplitude of Schrodinger's wave-function determines a probability. A general method is given for obtaining physical results from a mechanics that uses non-commutative multiplication. The theory for any number of degrees of freedom is worked out. The results obtained in this way appear to be the most general that can be got from quantum dynamics, and probably give all the information that the physicist requires. For the mathematical investigation a general transformation theory of matrices of matrix mechanics is here worked out.

T. R. Merton: On measurement of intensity of spectrum lines. The wedge method of determining the intensities of spectrum lines is discussed, and a new technique is described. A comparator has been constructed for rapidly identifying spectrum lines, and at the same time determining their intensities in terms of a standard continuous spectrum.

T. R. Merton: On temperature and pressure regulation in prismatic photographs. The errors in measurement and the loss in definition in prism spectrographs, due to variations in the temperature and barometric pressure, are discussed, and a description is given of methods by which these errors have been overcome.

Geological Society, Jan. 5.—**Charles S. Elton**: The nature and origin of soil-polygons in Spitsbergen. Polygonal soils are divided primarily into mud-polygons and stone-polygons. The mud-polygons are formed in two quite different ways: there are larger ones produced by frost-expansion of the soil in winter, and smaller ones formed by drying of the soil in summer. There are probably several factors at work in the formation of stone-polygons. A new factor is described in this paper; mixed materials become differentially arranged in a vertical direction, so that there is mud below, grading into stones on the surface. The mud freezes in winter, expands, and forms regular mud-polygons, invisible from the surface at that stage. Later, as the overlying stones become disintegrated, the centres of the mud-polygons reach the surface, and when they freeze in winter exert a lateral pressure forcing the stones outwards, forming at first, rings, and later, stone networks.—**Frank Dixey**: The tertiary and post-tertiary lacustrine sediments of the Nyasan rift-valley. The series of lacustrine sediments extending along the north-western shores of Lake Nyasa, formerly thought to be of recent age, are now known to include the deinosaur beds of late Jurassic or early Cretaceous age, as well as six groups of beds ranging through Tertiary and post-Tertiary times. These sediments extend over an area 78 miles in length and 12 miles in maximum width, and they occupy the floors of several minor rifts that run parallel with the main rift-valley. The beds extend increasingly farther inland according to their age, and the oldest group (the Sungwa beds) rises to a height of 1000 feet above the present level of the lake. The different groups rest upon the worn edges of the deinosaur beds and all older rocks, and they are themselves separated by a series of unconformities; moreover, the sediments all dip towards the floor of the main rift, and each group is inclined in this direction at a steeper angle than that of the group immediately overlying it.

Edinburgh.

Royal Society, Jan. 10.—**Miss Frances M. Ballantyne**: Air-bladder and lungs: a contribution to the morphology of the air-bladder of fish. A large mass of material, embryological and adult, of ganoids, lungfish, and teleosts has been examined. The facts brought forward help to complete the evolutionary history of the air-bladder of modern fish from the right lung of the primitive ancestral form.—**George Slater**: The structure of the disturbed deposits of Moens Klint and Lonstrup, Denmark. The disturbances of Moens Klint are local and superficial and extend for 4 miles. They may be divided into two groups, in each of which the structure shows a definite relationship to a 'core' of chalk, of asymmetrical or drumloid form of roche-moutonnée outline. Thrust planes are developed on the iceward limbs of the 'cores,' and these are associated with drift-deposits intercalated in the chalk. To the south of the area seven squeezed anticlines occur separated by thrust planes. The disturbances south-south-west of Lonstrup extend for 2¼ miles. The material involved consists entirely of drift of two types, 'clay and sand,' constantly repeated, and associated with thrust-planes. The structure differs from that of the Möen area in the fact that the beds have a uniform direction of dip to the north-north-east, but agrees with the phenomena seen at Möen on the iceward limbs of the 'cores.' The Lonstrup sections represent the tectonics of a stagnant glacier as reflected in the lower englacial material.—**Errol I. White**: The fish-fauna of the cementstones of Foulden, Berwickshire. This fauna consists chiefly of fishes, which, with the exception of a few large, widely distributed species represented by odd scales and teeth, are small local forms not previously described. Five new species are recorded, and of these four belong to new generic types of palæoniscids to which the names Fouldenia, Aetheretmon, Carboveles, and Strepheoschema are given: these are interesting on account of the specialisation they show in various directions, and specially to be noted are the degeneration of the squamation in Carboveles and the platysomid-like deepening of the body in Strepheoschema.

MANCHESTER.

Literary and Philosophical Society, Dec. 14.—**F. E. Weiss**: Some recent advances in our knowledge of inheritance in plants In the main, Mendel's work has been confirmed, but irregularities and exceptions have made subsidiary hypotheses necessary. The numerical ratios obtained by Mendel in the segregation of characters have been satisfactorily explained by the separation of the chromosomes in the reproductive cells, and Prof. Morgan and his collaborators in America have worked out a very complete theory of the actual distribution in the chromosome filaments of the material carriers or genes of the unit characters. Though Morgan's views have been generally adopted, they must still be regarded as open to criticism. Recently it has been shown that it is difficult to reconcile them with the fact that in different, closely allied species of Crepis the number of the chromosomes is different, yet without apparent loss of important characters. Variation in the number of chromosomes occurs in many plants. Certain giant races possess twice the number of the nuclear constituents, whereas in other cases varying numbers of chromosomes do not appear to have caused fundamental differences in the plant. Very variable genera such as Rosa, Rubus and Cratægus possess multiple numbers of chromosomes. Millardet's original discovery of complete inheritance in certain strawberry hybrids of all the characters of one of the parental plants, and an absence of subsequent segregation, has been confirmed, and occurs in a number of other plants. More attention will probably have to be paid in the future to the 'field' or environment in which the genes develop, and this may also throw some light on the conditions which produce changes of these genes and result in the formation of variations and mutations.

PARIS.

Academy of Sciences, Dec. 20.—**E. Goursat**: Some partial differential equations.—**Maurice Hamy**: Some experimental researches. A study of a method for evaluating the errors due to the eyepiece micrometer of meridian telescopes.—**L. de Launay**: The possible rôle of transmutations in geology. Outline of a theory concerning the formation of the chemical elements and their distribution on the earth.—**A. Desgrez, L. Lescœur, and Mlle. S. Manjean**: The influence of the ionic reaction on the decomposition of sulphide waters by a current of inert gas: hydrological applications. The effect on the rate of removal of hydrogen sulphide by a current of inert gas from a mineral water the pH of which has been changed by the addition of salts is shown in a series of curves.—**Benjamine Segre**: The generalisation of the transformation of Laplace.—**René Garnier**: Certain linear differential equations and the problem of Plateau.—**E. Vessiot**: Systems of equations and continuous transformations.—**Lainé**: An equation of the form $s = p\phi\ (x, y, z, q)$ integrable by the method of Darboux.—**Georges Valiron**: The values of the holomorph functions in a circle.—**Octave Onicescu**: The adjusting an ensemble of values.—**Paul Dumanois**: Concerning the use in internal combustion motors of slightly inflammable combustibles. A study of the conditions under which a petroleum product such as white spirit (boiling-point range 130°-180° C.) can be used in an aviation motor.—**P. Salet**: The constancy of the velocity of light. Reply to the criticisms of La Rosa on conclusions given in an earlier communication.—**P. Helbronner**: Results of the operations of the meridian chain of Corsica and of the junction of this with the islands of the Tuscan archipelago.—**Th. Vautier**: Forms and deformations of aerial waves.—**Pierre Bricout**: The value of the potential at the interior of a cluster of electrons in movement.—**G. Bruhat and M. Pauthenier**: The surface tension of insulating liquids submitted to the electric field. A thermodynamic proof that the surface tension of an insulating liquid is independent of the electric field.—**G. Colange**: The mechanism of the electrolytic interruptor. A description of a new type of electrolytic interruptor.—**A. Couder**: A new type of photographic telescope. An improvement of Schwarzschild's method, using two mirrors with a reflecting telescope.—**G. Vaugeois**: The influence of the nature of the support on the radon evolved — **Henri Belliot**: Photographic inversion by heat.—**E. Carrière and Ducasse**: Determination of boiling-point and dew-point curves of mixtures of hydriodic acid and water under a pressure of 746 mm. of mercury.—**Pierre Chevenard and Albert Portevin**: The influence of carbon and silicon on graphite formation in white cast irons. In the alloys studied the carbon varied from 1·7 per cent. to 4·5 per cent., the silicon from 0·2 per cent. to 6 per cent. The results are given in a three-dimension diagram, with silicon, carbon, and temperature of graphite formation as variables.—**H. Colin and Mlle. A. Chaudin**: The law of hydrolysis of saccharose by acids. A repetition of Wilhelmy's research with instruments of high precision on the inversion of sugar by acids (nitric acid, oxalic acid). The quantity $\frac{1}{t}\log\frac{a}{a-x}$ increased with time. From this it is concluded that the hydrolysis of sugar by dilute acids is not a simple monomolecular reaction, neither is it the resultant of two reactions one of which is instantaneous —**Mlle. Suzanne Veil**: The evolution of iron sulphide in contact with water. A study of the changes in the magnetisation coefficient of sulphide of iron produced by heating with water to various temperatures.—J. Cournot and Eugène Pérot: The cementation of aluminium by copper.—B. Bogitch: Concerning the granulation of scoria. In the process of granulating metals or slags by pouring the molten material into water, explosions are fairly frequent. These can be avoided or much reduced in number by taking certain precautions.—Charles Prévost: A closed cycle of reactions concerning some derivatives of erythrene.—Antonin Němec: The determination of the requirements of agricultural soils in phosphoric acid by the colorimetric method. The influence of lime and iron.—Ch. Brioux and J. Pien: The lime requirements of acid soils. Electrometric curves of saturation and the Hutchinson-MacLennan indices. Buffer action towards bases. Comparison of the results obtained by the Hutchinson-MacLennan calcium bicarbonate and electrometric methods showed good agreement. For soils of equal *p*H values, clay soils and soils containing much humus require more lime for neutralisation than light sandy soils.—Maurice Azéma: The mechanism of excretion in the Ascidiidæ.—Jacques Pellegrin: The disappearance of opposite fins in African fishes of the Clariineæ group.—Alphonse Labbe: An experimental phyletic line, Canthocampus ⟶ Cyclops.—Jean Jacques Trillat: The secondary action of the X-rays on micro-organisms. These experiments show the marked influence of the secondary radiations excited by the primary radiation on a metallic radiator placed near the micro-organisms. The bactericidal action is greater the higher the atomic number of the metal forming the radiator.—Henri Hérissey and J. Cheymol: The chemical composition of geine (geoside). The formula given is mainly based on the facts that hydrolysis with gease gives vicianose and eugenol in equal molecules, whilst hydrolysis with acids gives *d*-glucose, *l*-arabinose, and eugenol.—N. Bezssonoff: Is the antiscorbutic action due to two different substances?—J. Meunier and Mlle. G. Saint-Laurens: Human biliary calculi containing a high proportion of copper. Recent work has shown that the presence of copper in plant and animal tissues is fairly general, and its presence can now scarcely be regarded as accidental. The maximum amounts hitherto found are of the order of 60 mgm. per kilogram. The calculi examined contained 3 grams per kilogram.

Diary of Societies.

SATURDAY, JANUARY 29.

NORTH OF ENGLAND INSTITUTE OF MINING AND MECHANICAL ENGINEERS (at Neville Hall, Newcastle-upon-Tyne), at 3.—P. F. Hope: Steam and Electric Locomotives for Colliery Purposes.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—Prof. E. W. Tristram: English Medieval Wall-Painting (2).

INSTITUTE OF BRITISH FOUNDRYMEN (Birmingham, Coventry, and West Midlands Branch) (at Engineers' Club, Birmingham), at 6.30.—T. Teisen: Modern Gas-Fired Annealing and Other Furnaces.

WEST OF SCOTLAND IRON AND STEEL INSTITUTE.—Sir W. Larke: Steel Commercially Considered.

MONDAY, JANUARY 31.

CAMBRIDGE PHILOSOPHICAL SOCIETY (at Cavendish Laboratory, Cambridge), at 4.30.—Sir Joseph Larmor: What Determines the Resistance and Tilt of an Aeroplane?—L. H. Thomas: The Effect of the Orbital Velocity of the Electrons in Heavy Atoms on their Stopping of α Particles.—Dr. F. H. Constable: Surface Adsorption and the Velocity of Chemical Action at Gas-Solid Interfaces.—H. D. Ursell: The Evaluation of Gibbs' Phase Integral for Imperfect Gases.—*To be communicated by title only*:—Prof. G. H. Hardy: Note on Ramanujan's Arithmetical Function $\tau(n)$.—Prof. G. H. Hardy and J. E. Littlewood: Notes on the Theory of Series (iv.): On the Summability of the Fourier Series of a Nearly Continuous Function.—R. Vaidyanathaswamy: The Pedal (3, 2) Correspondence.—W. Hunter: Lines and Planes in a Metrical Space.

Institute of Actuaries, at 5.—V. P. A. Derrick: Observations on (1) Errors of Age in the Population Statistics of England and Wales, and (2) the Changes in Mortality indicated by the National Records.

Royal Society of Arts, at 8.—Dr. L. C. Martin: Recent Progress in Optics (Cantor Lectures) (3).

Royal Institute of British Architects, at 8.30.—Presidential Address to Students and Presentation of Prizes.

TUESDAY, February 1.

Royal Institution of Great Britain, at 5.15.—Prof. J. S. Huxley: Problems of Animal Growth and Development (1).

Institution of Automobile Engineers (jointly with Royal Aeronautical Society) (at Royal Society of Arts), at 7.—A. H. R. Fedden: The Supercharging of Aero Engines.

Institute of Metals (Birmingham Section) (at Engineers' Club, Birmingham), at 7.—Dr. G. D. Bengough: Corrosion.

Royal Photographic Society of Great Britain, at 7.—T. H. B. Scott: Presidential Address.

Institute of Metals (North-East Coast Section) (at Armstrong College, Newcastle-upon-Tyne), at 7.30.—C. E. Pearson: Methods of Measuring Temperatures.

WEDNESDAY, February 2.

Institution of Mining Engineers (Annual General Meeting) (at Institution of Mechanical Engineers), at 11 a.m.—H. E. Mitton: Miners' Dwelling-houses.—The Haulage of Men Underground. Report of a Committee of the South Yorkshire Coal Trade Association.—R. Clive: The Occurrence of Gas.—A. D. Brydon: Surveying Boreholes by the Briggs 'Clinophone' and 'Clinoscope.'—J. P. Rees: The Effect of Ventilation on the Cooling Power of the Air (Eleventh Report to the Committee on 'The Control of Atmospheric Conditions in Hot and Deep Mines').—Dr. J. S. Haldane: (a) The Maximum Efficiency of Heat-engines, and the Future of Coal and Steam as Motive Agents; (b) The Thermal Efficiency of a Carnot Engine.—At 2.30.—Dr. W. Hancock: (a) A New Hygrometer for Mines; (b) Local Air-conditioning Underground by Means of Refrigeration (Twelfth Report to the Committee on 'The Control of Atmospheric Conditions in Hot and Deep Mines').

Geological Society of London, at 5.30.—Prof. V. C. Illing: The Geology of the Naparima Region of Trinidad.—Dr. W. L. F. Nuttall: Tertiary Foraminifera from the Naparima Region of Trinidad.

Royal Society of Medicine (Tropical, Dermatology, and Therapeutics Sections), at 5.30.—Special Discussion on The Treatment of Leprosy.

Institution of Electrical Engineers (Wireless Section), at 6.—C. F. Phillips and others: Informal Discussion on The Purpose and Design of Broadcast Receivers.

Institution of Civil Engineers (Students' Meeting), at 6.30.—J. L. Hunt: Escalator Tunnels and other Works at Piccadilly Circus.

North-East Coast Institution of Engineers and Shipbuilders (Graduate Section) (at Bolbec Hall, Newcastle-upon-Tyne), at 7.15.

North-East Coast Institution of Engineers and Shipbuilders (Middlesbrough Branch, Graduate Section) (at Middlesbrough), at 7.30.—J. L. Taylor: Oil Tankers.

Royal Society of Arts, at 8.—N. Evers: Chemistry and the Supply of Drugs.

Society of Public Analysts and other Analytical Chemists (at Chemical Society), at 8.—T. H. Barry: Arsenic in Printing Inks.—G. D. Elsdon and J. R. Stubbs: The Immersion Refractometer and its Value in the Analysis of Milk.—Dr. P. Haas and Barbara Russell-Wells: Irish Moss Mucilage and a Method for its Determination.

Eugenics Society, at 8.

THURSDAY, February 3.

Royal Society, at 4.30.—Prof. W. A. Bone and A. Forshaw: Studies upon Catalytic Combustion. V. The Union of Carbonic Oxide and other Gases with Oxygen in Contact with a Fireclay Surface at 5000° C.—A. Egerton and S. F. Gates: (a) On Detonation of Gaseous Mixtures of Acetylene and Pentane; (b) On Detonation of Gaseous Mixtures at High Initial Pressures and Temperatures.—M. W. Garrett: Experiments to Test the Possibility of Transmutation by Electronic Bombardment.—F. C. Lay, W. Ll. Prichard, and J. A. Sutcliffe: The Latent Heat of Vaporisation of Benzene at Temperatures above the Boiling Point.—H. A. Fells and J. B. Firth: (a) The Function of Water present in Silicic Acid Gel. The Structure of Silicic Acid Gel, Part II.; (b) The Phenomena arising from the Addition of Hydrogen Peroxide to Silicic Acid Gel.—E. Newbery: Anodic Overvoltage Measurements with the Cathode Ray Oscillograph.—C. Cuthbertson: (a) Absorption of Radiation in the Extreme Ultra-violet by the Inert Gases; (b) On a Relation between the Refractive and Dispersive Constants of the Inert Gases.—Prof. C. V. Raman and K. S. Krishnan: The Diffraction of Light by Metallic Screens.—R. G. Fraser: The Effective Cross Section of the Oriented Hydrogen Atom.—Sir Richard Paget: The Nature and Artificial Production of the, so-called, Voiced and Unvoiced Consonants.—L. Pauling: The Theoretical Prediction of the Physical Properties of Many-Electron Atoms and Ions.—B. F. J. Schonland and J. Craib: The Electric Fields of South African Thunderstorms.—Prof. J. C. McLennan, J. H. McLeod, and W. C. McQuarrie: An Investigation into the Nature and Occurrence of the Auroral Green Line λ 5577 A.—Sir Almroth Wright: A Further Contribution to the Study of the Phenomena of Interaction.

Royal Institution of Great Britain, at 5.15.—Sir William Bragg: Acoustical Problems treated by Lord Rayleigh: (1) Æolian Tones.

Institution of Electrical Engineers, at 6.—Lt.-Col. K. Edgcumbe and F. E. J. Ockenden: Some Recent Advances in Alternating-Current Measuring Instruments.

Society of Chemical Industry (Chemical Engineering Group) (jointly with Bristol and Fuel Sections) (at Bristol University), at 7.30.—J. W. Reber and M. Scott: Production of Power from Towns' Refuse.

Chemical Society, at 8.—J. W. Baker and Dr. C. K. Ingold: The Nature of the Alternating Effect in Carbon Chains. Part XIV. The Directive Action of Some Groups of the Form $-CR'R''.CO.R$ in Aromatic Substitution.—J. W. Baker and L. S. Wilson: The Nature of the Alternating Effect in Carbon Chains. Part XVII. The Directive Action of the Groups $.CH_2.CH_2.NO_2$, $.CH:CH.NO_2$ and $.C(NO_2):CHR$ in Aromatic Substitution.—A. Ferguson and I. Vogel: (a) The Storch Equation, a General Dilution Formula and the Validity of the Law of Mass Action at Limiting Dilutions; (b) The Calculation of the Equivalent Conductivity of Aqueous Solutions of Strong Electrolytes at Infinite Dilution. Part II. Application to Data at 0°, 18°, and 25° C.; (c) The Calculation of the Equivalent Conductivity of Aqueous Solutions of Strong Electrolytes at Infinite Dilution. Part III. The Mobilities of the Hydrogen and the Hydroxyl Ions.

Röntgen Society (at British Institute of Radiology), at 8.15.—Dr. J. M. W. Morison: New Radiological Department, the Royal Infirmary, Edinburgh.—H. D. Griffith: The Physics of Carbon Arc Therapy.

Institution of Mechanical Engineers (Glasgow Branch).—Prof. A. L. Mellanby and Prof. W. Kerr: Use and Economy of High Pressures in Steam Plant.

Institution of Mechanical Engineers (Manchester Branch).—E. W. Tipple: Machine Tools.

FRIDAY, February 4.

Royal Society of Medicine (Laryngology Section), at 5.

Geologists' Association (Annual General Meeting) (at University College), at 7.—Presidential Address: Some Aspects of the Mountain Building Problem.

Society of Chemical Industry (Manchester Section, jointly with Manchester Section of Oil and Colour Chemists' Association) (at 16 St. Mary's Parsonage, Manchester), at 7.—C. W. Gamble: The Constants of Colour—Hue, Purity, and Luminosity.

Institution of Mechanical Engineers (Informal Meeting), at 7.—W. Reavell: Engineering Salesmanship.

Royal Photographic Society of Great Britain (Pictorial Group), at 7.—W. L. F. Wastell: Psychology and the Print.

Photomicrographic Society (at 4 Fetter Lane), at 7.—H. Wrighton: The Photomicrography of Metals.

Junior Institution of Engineers, at 7.30.—P. R. Jackson: The Theory of the Gyroscopic Compass.

Philological Society (at University College), at 8.—Prof. E. Weekley: Romance Notes.

Royal Institution of Great Britain, at 9.—Prof. E. V. Appleton: Wireless Transmission and the Upper Atmosphere.

Oxford University Junior Scientific Club.—Speaker—Mr. Hodges.

SATURDAY, February 5.

Royal Society of Medicine (Otology Section), at 10.30 a.m.—Dr. C. P. Symonds: Cerebral Abscess; Some Points in Diagnosis and Localisation.—Dr. Farquhar Buzzard: The Treatment of Traumatic Facial Paralysis.

Royal Institution of Great Britain, at 3.—W. de la Mare: Craftsmanship in Verse.

PUBLIC LECTURES.

SATURDAY, January 29.

Horniman Museum (Forest Hill), at 3.30.—Miss M. A. Murray: Some Invasions of Ancient Egypt.

SUNDAY, January 30.

Guildhouse (Eccleston Square), at 3.30.—Rabbi Dr. I. Mattuck: The Soul of Judaism.

MONDAY, January 31.

King's College for Women (Household and Social Science Department), at 5.15.—F. Hodges: The Future of the Mining Industry.

TUESDAY, February 1.

Bedford College for Women, at 5.15.—Sir Thomas L. Heath: Conceptions of the Cosmos in the Classical Period.

University of Birmingham.—Prof. G. Elliot Smith: Science and Culture (Huxley Lecture).

WEDNESDAY, February 2.

King's College, at 5.30.—Dr. O. Vočadlo: The Wends: The Ancient Slavonic Inhabitants of Northern Germany.

University College, at 5.30.—Major W. E. Simnett: Special Libraries.—At 6.—Prof. A. L. Bowley: Tests of the Trustworthiness of Public Statistics (Newmarch Lectures) (1).

THURSDAY, February 3.

King's College, at 5.30.—Dr. J. A. Hadfield: The Mind: Psychotherapy.

Northampton Polytechnic Institute, at 7.—R. Genders: Steel and its Thermal Treatment: Engineering and other Special Steels.

Royal Society of Arts, at 8.—Prof. C. H. Reilly: Developments in Building Methods (Chadwick Public Lecture).

Fulham Public Library, at 8.—Dr. J. R. Leeson: The Infinitely Small and the Infinitely Great: The Structure of the Universe from the Electron to the Nebula.

FRIDAY, February 4.

London School of Economics, at 5.—F. Debenham: The Economic Aspects of the Polar Regions. (Succeeding Lectures on February 11 and 18.)

SATURDAY, February 5.

Horniman Museum (Forest Hill), at 3.30.—V. Gordon Childe: The Aryans, our Linguistic Ancestors.

SUNDAY, February 6.

Guildhouse (Eccleston Square), at 3.30.—Maulvi A. R. Dard: The Soul of Islam.

SATURDAY, FEBRUARY 5, 1927.

Education of the Adolescent.[1]

TO form and to strengthen character; to train tastes which will dignify leisure; to awaken and guide intelligence, especially on its practical side: these are the three ends which the Consultative Committee of the Board of Education had in mind when framing the recommendations which have been embodied in its Report on the Education of the Adolescent, and, even though we may have some difficulty in discovering the exact dividing line between the qualities of the second and third, we must admit that they are ends which, if attained, would make formal education almost as vital to human life and activity as nutrition and reproduction.

There are, of course, many forces which operate against the attainment of such ends, and not the least is the attitude of mind of the very committees which make such valuable recommendations. Let there be no mistake: if, as we shall attempt to show later, the present Committee has not been infallible, there can nevertheless be no doubt that it has faced its problems with unusual breadth and clarity of vision. It has faced boldly—whether the revision and extension of school nomenclature it suggests receive approval or not—the inevitability of a regrading of education, and it has not lacked the courage to recommend the raising of the school leaving age. It has left no avenue unexplored, and it has neglected no statistical detail in order that, so far as it could see them, no factors of the present system should be avoided in its argument. Not forgetting that "a community must solve its . . . problems in accordance with its own traditions and customs," the Committee has carefully examined the history which has brought these factors into being, and has lucidly set forth the lines of advance which it believes will lead to a system capable of securing for its pupils the benefits we have described. Nor has it shirked the issue of demonstrating how its recommendations may be made administratively possible.

These points, in themselves, are perhaps sufficient to demonstrate with what sense of responsibility the Committee regarded terms of reference which not only requested attention to the organisation, objective, and curriculum of courses of study for children (other than those attending secondary schools) who will remain in full-time school attendance up to the age of fifteen, but also that regard should be had to their probable future occupations in commerce, industry, and agriculture—a feature which led the Committee at an early stage in its report to make a pronouncement so important that we need not apologise for its reproduction: "The educationalist, unless he would build his castles in the air, is bound at every turn to take into account the probable future of the children and the nature of the industrial society into which . . . the majority will enter." Or, again: "School and industry are different facets of a single society, and the habit of mind which isolates them is a habit to be overcome."

---

[1] Board of Education. Report of the Consultative Committee on the Education of the Adolescent. Pp. xxiv+339. (London: H.M. Stationery Office, 1926.) Paper, 2s. net; cloth, 3s. net.

Reading that, the technical teacher might well begin to congratulate himself that, at last, the liberal quality, as well as the importance of his work, was being recognised; and he would be strengthened in his view when he read, further, a recommendation which begins: "A humane and liberal education is not one given through books alone, but one which brings children into contact with the larger interests of mankind." If he read still further, however, he would discover that the Committee is discussing the proposed 'Modern' (at present 'Central') Schools, and that when it realises whither the argument may lead, seems to become suddenly fearful and is careful to point out that it is *not* suggesting any wide extension of Junior Technical Schools, but that the 'modern' school should develop with a 'realistic' or 'practical' bias and should not aim "at giving a technical or vocational education." He would see that the Committee's attitude towards technical education is one which fits but ill with the philosophical statements which preceded his search. A little puzzled, he would turn to the Committee's definition of this word 'bias,' and find his dilemma still further increased. Finally, he would lose the last vestige of his optimism when he discovered the Committee's view that a foreign language is regarded as necessary in the modern school, but its necessity in the Junior Technical Schools —even though its lack may be a barrier against matriculation and entry into the learned institutions—is set out in very guarded terms. He will not, therefore, be very much to blame if he thinks the work of technical education is still but little understood, and that the ancient and arid arguments between the values of 'arts' and 'sciences,' and between 'pure' and 'applied' science are not yet at an end. A crumb of comfort will fall to him, however, when he reads that, on suggested examination boards, "Technological teachers might be co-opted."

If, in its view and knowledge of the work of technical schools, the Committee has not been infallible, it is beyond doubt that it has been very largely influenced by the inevitable trend towards the linking up of education and industry. It has not failed to observe that the modern development of industry has resulted in a loss of craftsmanship and an increase in leisure, due to the lessening hours of labour, and it has therefore rightly regarded the school as an instrument which can do much to counteract the loss of craftsmanship and to secure that leisure may be wisely used. In this connexion it has laid some stress upon handwork, and, in addition, to recommending that a sufficient number of teachers must have the craftsman's interest and outlook; it has given evidence of its recognition of another important question by its suggestion that girls as well as boys should learn something of the use of tools, and should be allowed to take a short course in wood and metal work.

There is not, perhaps, much that is new in the Committee's suggestions on the teaching of science. The interdependence of the various subjects is clearly indicated. Not only is the science teacher to keep closely in touch with the teachers of drawing and mathematics, but also "simple apparatus might be made by pupils in wood and metal lessons." In the case of girls, the science courses of the Modern Schools should, in their later stages, have a biological trend; and the work should not, as is frequently the case, be confined to botany. The reasons given for this recommendation show that the Committee has taken care that the liberal qualities of science teaching shall be thoroughly understood, and that it shall not aim at the assimilation of unrelated facts. "The study of simple forms of animal life can . . . be made an admirable means of widening and disciplining the pupils' sympathies" and will increase happiness and efficiency. In the same way, for boys and girls, instruction in biology and elementary physiology "might well provide the basis for a right attitude to many social problems." To the initiated these suggestions may form part of an accepted philosophical attitude towards education—especially on its scientific side—which is almost a *sine qua non* of a rapidly developing society. For our part we welcome them, since we do not lack evidence that words and actions are often poles apart, and we realise that there cannot be too much examination and repetition of fundamentals.

If post-primary education is to be a unity in the full sense of that word, we may be pardoned if we refer to a subject sometimes (wrongly) regarded as outside our province. In dealing with the teaching of history, the Committee has dealt well with the view that it is a study of the organised life of a community, and has regarded part of its function as the enabling of the pupil to see the present as a development of the past. On our side we are tempted to regard the present as but a thin dividing line between the past and future. Doubtless the Committee holds the same view, but until the science section of the Report is reached we do not observe any suggestions which would mean the presentation of any historical view of what science has done for mankind. In these days of the cinema, aircraft, wireless telephony and broadcasting, it seems to us an essential part of a liberal education that the influence of science in breaking down the barriers of space, and in drawing together people who formerly were antagonistic because of their lack of mutual understanding, should have some definite part in the most formal teaching of history.

We willingly run the risk of being told that we are not aware of the correct place of such teaching. For the moment we regard it as sufficient that the point be made, and, while waiting for the later pronouncements upon such an important theme, we may leave it quite safely in the hands of the teachers of science.

Modern Occultism.

Der physikalische Mediumismus. Von Dr. W. v. Gulat-Wellenburg, Graf Carl v. Klinckowstroem und Dr. Hans Rosenbusch. ("Der Okkultismus in Urkunden," herausgegeben von Max Dessoir.) Pp. xiv + 494 + 15 Tafeln. (Berlin: Verlag Ullstein, 1925.)

THIS imposing volume is known in Germany and Austria as the "Dreimännerbuch." It is the first of a trio of books intended to deal exhaustively with modern representatives of those 'occult sciences' which have never ceased to occupy a certain type of mind since the days of Paracelsus. The increasing habit of civilised humanity to submit all such 'hidden' sources of knowledge to examination by modern scientific methods has driven their advocates and devotees to adopt at least an apparently up-to-date terminology.

Thus we do not hear much about the Secret Rose, the Elixir of Life, or the Fifth Essence. But we are told all the more about Psychophysical Energy, Metapsychics, Rigid Rays, Telekinesis, and Ectoplasia—imposing words which to many minds convey an irresistible suggestion of reality.

It would of course be impossible to deal in one book with the vast volume of occult literature, nor do the 'three men' make any attempt to do so. But they do pass in review what may be called the serious treatments of the subject, and the sporadic attempts to apply some scientific method to the study of alleged phenomena which seem to contradict well-known physical and biological laws.

Of the three authors of this book, Count von Klinckowstroem deals with the "Confessions of a Medium" as well as classical mediums like D. D. Home, Florence Cook, Slade, Guzik, and Mrs. Gilbert. Dr. Rosenbusch studies Eusapia Paladino, Stanislava Tomczyk, and Kathleen Goligher, while Dr. von Gulat-Wellenburg examines the claims of Marthe Béraud ('Eva C.'), Franck Kluski, Willy Schneider, Nielsen, and Laszlo.

It may seem a deplorable waste of time and energy to devote five hundred pages of close print to the criticism of alleged phenomena which have been almost unanimously rejected by the scientific world. But it is necessary to remember that we are here dealing with alleged happenings which, if authenticated, would necessarily change our whole outlook on the possibilities of life and even of non-living matter. Even in their unproven state these alleged observations are exerting a very wide influence on great masses of contemporary thought and feeling. To millions they form the basis of a new religion purporting to have a sound scientific basis. One cannot envy the fate of the few leaders of science whose names are perennially quoted as supporting and sanctioning spiritualist practices. The name most widely exploited in this connexion is that of the late Sir William Crookes, whose few experiments, undertaken without appropriate training and then abandoned, have formed a peerless model for all later investigators and imitators.

The truth appears to be that these 'supernormal' phenomena bring us face to face, not so much with a higher world of spirit as with an underworld of human credulity, based upon an irresistible appetite for the marvellous. This appetite or need has always existed; and it has always rebelled against the established order of things. It has always postulated the existence of beings superior to it, whether angels or jinns or the spirits of the dead. Who can wonder that men trained in scientific methods have sometimes shown a similar weakness! Physicists show this tendency perhaps more than others. But that may be due to the fact that their researches are the most fundamental as regards the structure of the universe. They work on the very frontier of the unknown, and their recent discoveries are so marvellous that a miracle more or less does not seem to signify.

The modern attempt to erect occultism into a science was supported, if not initiated, by Alexander Aksakof, whose "Animism and Spiritism" advocated the view that spiritistic phenomena were not due to disembodied intelligences but to unexplained powers of the human organism itself. It was he who coined the word 'telekinesis' for movement without contact, and one cannot help wondering how many conjuring tricks, clever or otherwise, have since been dignified by that beautifully fashioned Greek word. It was Dr. Ochorowick who invented 'ectoplasy,' though it did not become popular until F. W. H. Myers defined it in his work on "Human Personality and its Survival of Bodily Death." He called it "the power of forming outside some special organism a collection or reservoir of vital force or of vitalised matter which may or may not be visible or tangible but which operates in like fashion as the visible and tangible body from whence it is drawn."

Many attempts have been made to investigate this mysterious 'vitalised matter' and to define its properties. If we were to take the current spiritualist view, ectoplasy, or rather 'ectoplasm,' would be the substratum of all 'materialisations,' even of full figures like Crookes's Katie King, *plus* her calico dress. It would also constitute the 'rigid rays' emanating from the fingers of Mlle. Tomczyk, the 'psychic rods' of the Goligher circle, and the plastic structures described by Dr. v. Schrenck-Notzing. The latter were supposed to consist of amorphous material capable of assuming any form or appearance suggested by the medium's subconscious mentality. Thus they sometimes showed the structure of half-formed faces in plaster-of-Paris, which were ascribed to the frequent visits of the medium to a sculpture studio.

According to Schrenck-Notzing the ectoplastic structures are very sensitive to illumination and to touch. 'Katie King,' in Crookes's charmed circle, could cut off strips of her dress, and materialise them permanently enough to be examined in daylight. But ordinarily the material is fugitive in light, and contact is not allowed for fear of injuring the medium.

Here again it is difficult to arrive at any sort of consistency. Dr. Crawford was allowed to touch a 'psychic rod.' It felt like a stockinged foot, with toes complete, but the medium was neither hurt nor injured by the touch. Also, did not v. Schrenck-Notzing himself take a kinematograph picture of a materialisation without inflicting any injury ?

A biologist inclined to credit the existence of ectoplasm endeavoured some time ago to form some intelligible conception of it by supposing it to partake of the nature of pseudopods put out by unicellular organisms. But this would scarcely account for Katie King's obviously woven calico. The late Dr. Crawford's speculations concerning 'X' and 'Y' matter building up 'psychic rods' capable of lifting tables and adhering to carmine and other pigments cannot be taken seriously, in view of the total absence of scientific control of the Goligher circle. Nobody has as yet put forward a description of 'ectoplasm' which will cover the various forms of its alleged occurrence or permit of any consistent theory as to its properties. Even the assertion that it emanates from the epithelium of any natural orifice of the organism fails to cover cases where it is alleged to emanate from the fingers. The analysis of a fragment of the substance said to have been isolated by Dr. v. Schrenck-Notzing showed nothing but epidermis such as might have been peeled off a human heel.

The authors of the "Dreimännerbuch" must be congratulated on the minute and serious analysis of all 'supernormal' phenomena which have been vouched for by persons of any scientific standing. Their criticism is objective and temperate, and in all cases where a normal explanation is difficult or impossible they frankly admit its being so. One is therefore inclined to give all the more weight to their main conclusion, which is that the scientific proof of the reality of physical mediumistic phenomena has never yet been furnished, all the alleged phenomena being capable of a normal explanation based upon deception or inadequate observation. The only cases which they are inclined to leave in doubt are certain reports concerning D. D. Home and a few experiments with Eusapia Paladino. But even these are now of little value owing to the impossibility of repetition.

That the phenomena in question are rare and elusive does not in itself deprive them of scientific interest. But it is becoming increasingly clear that any hope of their substantiation depends upon the provision of competent observers. The qualifications of such observers must be very high, much higher than in the case of ordinary physical and biological investigations. Not only must the psychic researcher be acquainted with all the abnormalities of vision in a feeble light and under prolonged strain, but he must also be versed in the numberless possibilities of deliberate deception and trickery. The ordinary physicist or biologist is quite incapable, as a rule, of explaining a clever conjuring trick performed in a bright light. Yet he will sometimes assert that all possibility of fraud was excluded in circumstances which would make a conjurer smile.

No new observations can in future be taken seriously unless the observer shows a close acquaintance with the sources of error involved in these investigations. In this respect the "Dreimännerbuch" furnishes a valuable test of knowledge. Considering that the English-speaking world is more obsessed by spiritualism than the rest of civilised mankind, an English translation of this book would fill an important place by the side of Myers and Podmore.

German Handbooks of Physics.

1) *Handbuch der Experimentalphysik*. Herausgegeben von W. Wien und F. Harms. Band 2: ***Mechanik der Massenpunkte und der Starren Körper***. Von Prof. Dr. Arthur Haas. Pp. xiv + 355. (Leipzig: Akademische Verlagsgesellschaft m.b.H., 1926.) 30 gold marks.

2) *Handbuch der Physik*. Herausgegeben von H. Geiger und Karl Scheel. Band 1: *Geschichte der Physik; Vorlesungstechnik*. Redigiert von Karl Scheel. Pp. vi + 404. (Berlin: Julius Springer, 1926.) 31·50 gold marks.

THE progress of physics during the last few decades has been truly remarkable, and it is with a feeling akin to hopelessness that the present-day physicist vainly attempts to keep abreast of the times. As the science has developed, specialisation has become more and more necessary, and it is to this intensive specialisation that physics owes its present vastness. In such circumstances, the need for an up-to-date "Handbook of Physics" for purposes of reference has become increasingly urgent, and it was to be expected that sooner or later such a work would be forthcoming. In English, the "Dictionary of Applied Physics" serves a useful purpose in enabling physicists to have easy access to recent developments in the divers branches of their subject, and in German, apart from several excellent handbooks on special branches, Winkelmann's "Handbuch" has done valuable service, though it is now somewhat out-of-date.

The deficiency is now being rectified, and there are at present in course of publication two distinct 'handbooks' of physics. One of these, the "Handbook of Experimental Physics," is being edited by Wien and Harms. Its aim is to give a detailed presentation of modern physics and geophysics from the experimental viewpoint, and to introduce only that minimum amount of theory necessary for the intelligibility of the actual facts, in view of the tendency of modern theory to age as fresh experimental material accumulates. For obvious reasons of uniformity, the number of contributors to the work has been kept as low as is consistent with an authoritative treatment of the various branches of the subject. Geiger and Scheel are primarily responsible for the editing of the other "Handbook of Physics." The number of contributors is larger than in the work of Wien and Harms, and the scope of the 'handbook' is more comprehensive, for it aims at giving a complete survey of the current position of theoretical as well as of experimental physics.

The list of distinguished scientific workers contributing to these two 'handbooks' is a guarantee of the excellence of the finished products. Nevertheless, one cannot suppress a feeling of regret at the publication simultaneously of *two* monumental works, the expressed aims of which are so similar. Surely one such work would have sufficed to fill the gap in current literature. Each 'handbook' is to comprise some twenty or more volumes, at a total cost of anything from forty to sixty pounds. Few private individuals can afford such an outlay for a comprehensive work on physics, and whereas most scientific libraries will endeavour to procure one or other of the handbooks, it is equally certain that they will be unable to procure both. The volumes can, however, be obtained separately.

(1) Vol. 2 of the Wien-Harms 'handbook' is entitled "The Mechanics of Particles and of Rigid Bodies." This is probably the most difficult of the various branches to bring within the scope of a handbook of experimental physics, for in it experiment plays a much less predominant part than in other branches of physics, and it has reached such a state of development that it has fewer fundamental advances to record than have other departments of the subject. For this reason, and we believe wisely, Prof. Haas has departed from the acknowledged form of 'handbooks,' usually so full of detailed references to the literature, and the result is very pleasing.

The book is divided into three parts, the first dealing with the motion of a particle, the second with the mechanics of a rigid body, and the third being devoted to the mathematical treatment of the mechanics of rigid bodies. The first two parts are comprehensive, but essentially elementary in their mode of treatment, and only the most important results of theory are presented, in so far as they are of importance in experimental physics. The experimental foundations of the theory and the comparison of the results of theory and experiment are discussed, and particular attention is given to mechanical problems which are important in the physics of measurement. The mathematical development of the subject has been intentionally relegated to the third part of the volume, so as to simplify the task of the less mathematical reader.

In accuracy of thought, logical development, and clearness of expression, the author is a master, and it would be difficult to imagine a more admirable treatment of the fundamental conceptions of kinematics than we find in the opening chapter of the book. Equally good are the chapters on pendular motion, processes of motion on the rotating earth, celestial mechanics, and gyroscopic motion, to mention but a few.

Free use of vector notation is made in the third and essentially mathematical part of the book. As the various results are derived, the appropriate references to the earlier non-mathematical sections of the text are given. This last section of the volume is perhaps the most valuable of all, for the treatment, though brief, is masterful, and contains all the essential steps in the development of the numerous results.

The book is attractively produced, and contains more than two hundred illustrations, carefully done, which add greatly to its clearness. The volume concludes with a list of references to recent literature on the experimental aspects of such topics as general and terrestrial gravitation, gyroscopic phenomena, and friction between solid bodies.

We have learned from experience to expect something good from Prof. Haas, and once again we are not disappointed.

(2) Vol. 1 of the Geiger-Scheel 'handbook' is devoted to the history of physics and to the technique of lecture experiments. It comprises four chapters—rather an odd term, in view of the fact that the second and third chapters together occupy only twenty-eight of the four hundred pages in the book.

The history of physics (Chap. i.) has been admirably written by an acknowledged authority on the subject, Prof. Hoppe of Göttingen. In one hundred and eighty pages we are provided with a fascinating account of the progress of physical science from Babylonian times up to the year 1895. The first section deals with the contributions of the Babylonians, the Egyptians, the Greeks, and the Arabians, and concludes with a review of scientific advance in Christian Europe as fa as the year 1600. At this point was initiated period of sound progress, when men like Keple and Newton placed the subject on an exact basis and freed it from methods of idle speculation whic all too frequently characterised the work of thos who preceded them. The second section of th chapter is concerned with this period of intensiv growth, and brings us to the year 1842. In th third and final section, which ends with the yea 1895, we pass in review the work of Kelvin Helmholtz, Maxwell, and their contemporaries, an are led from classical physics to the fringe of moder atomic physics, for the chapter concludes wit the discovery of radium and polonium. Detaile references are to be found on almost every page This interesting account of the development physics through the ages arouses feelings of regre that more time is not devoted, in academic course to the history of physics. Text-book physics ofte tends to give us a wrong sense of perspective i the development of the subject, for it has frequentl happened that great advances have been stimulate by the use of hypotheses accepted at the tim but later shown to be untenable. Prof. Hoppe ha endeavoured to give a balanced treatment of th growth of physical knowledge, and to place th historical evidence in its right perspective; th result makes informative and instructive reading.

Prof. Scheel contributes a brief but interestin account (Chap. ii.) of the development of th research literature of physics, commencing wit the *Philosophical Transactions of the Royal Society* which first appeared in 1665, and ending with th "International Critical Tables" of the Nation Academy of Science and the National Researc Council, the first volume of which appeared i 1926. In Chap. iii., Prof. Timerding gives critical account of the teaching of physics i elementary and in high schools. Although hi remarks have particular reference to German conditions, many interesting and generally applicabl aspects of the question are discussed. Teachin and research in the universities are also dealt wit and an account is given of the establishment an development of scientific societies and researc institutes, and of research publications.

The importance of experimental lecture demonstrations in university courses of physics has lon been recognised, and although the main lines experimentation are more or less fixed, eac department of physics has its own little specialitie University teachers are constantly on the look ou for new or modified experiments for lecture courses, and the editors of this 'handbook' have wisely included a section (Chap. iv.) on the technique of lectures, by Drs. Mecke and Lambertz, both of the University of Bonn. Many hundreds of representative lecture experiments on all branches of physics are described, numerous tables of data are given, and the text is copiously illustrated by excellent diagrams, many of which can be obtained from Dr. Mecke in the form of lantern slides. This collection of lecture experiments well repays careful study, and should prove invaluable to university lecturers in physics.

The volume under review is nicely printed on good paper, and is remarkably free from misprints. On p. 235, Fig. 21 has been erroneously inverted, and on p. 268 the melting point of mercury is given as 39° C.! R. W. L.

Primitive Ferns.

The Ferns (Filicales): Treated Comparatively with a View to their Natural Classification. By Prof. F. O. Bower. (Cambridge Botanical Handbooks.) Vol. 2: The Eusporangiatæ and other relatively Primitive Ferns. Pp. vi + 344 + 1 plate. (Cambridge: At the University Press, 1926.) 30*s*. net.

> "On a far-looking tower I stood to watch,
> And three tribes I beheld, of war-bands three."

THE prologue of this second volume on the ferns, opening as it does with this apt quotation from Way's translation of Euripides' "Suppliants," serves well to define the author's position in dealing with his theme. For having in his first volume built for himself a basis of morphological criteria, drawn from the entire range of fern life, he now proceeds to use it as a point of vantage from which to view the group as a whole. As the armies in the Greek play were seen to be formed in three distinct columns, each moving independently, so also the author sees three main phyla of ferns progressing from geological time in an evolutionary march, at first distinct and mainly divergent, but later converging in character in the more recent stages of phyletic advance. As in the battle graphically described in the play, the several columns finally merged in an inextricable mêlée, so in the later phases of fern evolution does the writer find the advanced members of his group, and his task of complete segregation of the several phyla of descent, according to their detailed features, grows in difficulty.

The broad basis of comparison which Prof. Bower has raised in his first volume, with the view of phyletic seriation of the ferns, is skilfully built on the values which he assigns to morphological features, each of which he has sought to weigh truly. The external morphology of the shoot, the internal constitution of the plant body as indicated by segmentation, the architecture and venation of the leaf, the vascular system, the dermal appendages, the position and structure of the sorus, the indusial protections, the characters of the sporangium and of the spores, the spore-output, the morphology of the prothallus, and the embryology of the sporophyte, have all fallen under his critical judgment during his lifelong and intensive study. Each he has examined critically in the ferns at large, and his views have not passed unchecked by the fossil records.

As the analysis has proceeded the conclusions have become more acceptable that the simple shoot, radial in construction, and commonly unbranched, is primitive, while the prone, dorsiventral, and unequally branched shoot is almost undoubtedly derivative. In relatively primitive ferns there are several initial cells in the apices of stem, leaf, root, and sporangium, while in later derivative types there is usually a single initial cell in the apices of these organs. The primitive forms of leaf are characterised by a dichotamised distal region, sometimes with basal stipular growths, and by leaf-segments which may be all separate, and each provided with a single vein. The primitive venation is open with free endings. In advanced ferns the leaf may be webbed, the venation reticulate, and the lower pinnæ arranged monopodially. The primitive axis is protostelic, the more advanced solenostelic, dictyostelic, polycyclic, or marked by further complications. Dermal appendages in the form of simple hairs constitute a primitive feature, while branched hairs, and in particular flattened scales, are held to be indicative of advance from simple hairs themselves. The marginal position of the sorus, more frequent in early than in late fern types, has passed in several distinct phyletic series into the superficial, as the area of the leaf-blade increased. The individuality of the sorus has also been lost in many sequences by fissions or by fusions, or the sori have been obliterated in time by spreading of the sporangia generally over the leaf-surface. The most important variations are, however, those of constitution of the sorus, three types of which have been distinguished, namely, the simple, gradate, and mixed. The first is characteristic of Palæozoic ferns, though it survives to the present day. The last is to-day prevalent but is absent in Palæozoic ferns. The gradate sorus is an intermediate type in many, but not all, phyletic lines.

There is no indusial protection in Palæozoic ferns, nor is such found in certain modern advanced types. But between such extremes protection by various means is provided notably by different types of indusium. The indusiate sorus is thus considered a later and derivative type, while on the other hand there is good evidence that the modern non-indusiate state has often resulted from the abortion of an indusium previously present. In the progression from Palæozoic to modern times the sporangium shows consistent reduction in size, with increasing specialisation of the mechanism of spore dispersal, while the sporangial form, length of stalk, and the position of the annulus and the stomium vary likewise in close relation to the constitution of the sorus. A gradual diminution of the spore-number accompanies the reduction and specialisation of the sporangium from geological time onwards. There is little to be gleaned for phyletic purposes from the vegetative features of the prothallus, though a surer basis for comparison seems to be provided by the sexual organs, and in particular by the antheridia, which are not only deeply sunk in the prothallus of the primitive ferns, but are also there massive, while in the more advanced types they project and are relatively delicate. As to the embryology of the ferns, it is held that the primitive embryo was probably a spindle-like structure with suspensor and shoot, while the root is an accessory organ of later development. The presence or absence of a suspensor is regarded from the phyletic viewpoint as the most important comparative feature relating to the fern embryo.

With the field of comparison thus widened the author proceeds to the detailed consideration of certain families which are held to be the most ancient among known ferns. These are the Cœnopteridaceæ and Osmundaceæ, which have had undoubted Palæozoic existence. With them are closely grouped for comparative reasons the Marattiaceæ and Ophioglossaceæ, as they also are Eusporangiate ferns.

The remainder of the ferns, though prefigured in some measure by fossils of the Palæozoic period, first began to assume their ordinary characters in the Mesozoic period or later. Their relationship is clearly with two relatively primitive families, namely, the Schiziaceæ and the Gleicheniaceæ, both of which became firmly established in early Jurassic times. The former bears its sori on the margins of the leaves, the latter produces them superficially. With their allies they constitute tw consistently defined series, the Marginales and th Superficiales, and are regarded as having no improbably originated from some common earlie source.

To the discussion of these fascinating an primitive families this beautiful book is mainl devoted. With consummate skill in presentation c fact and argument, and with a wealth of illustratio to illumine the written page, the author carries th reader through the intricacies of form and structur which the ferns display. It is only when th closing chapters are reached and the general revie of the primitive ferns as a whole has been read, tha a full appreciation is gained of the power of th argument which has guided the author throughou the arduous task of phyletic grouping. The consideration of the more advanced series of ferns i delayed to a later volume, but to all who read thi book must come a growing desire for the productio at an early date of the remainder of this fascinatin narrative of the march of evolution.

Measurements of the Cubical Contents of Fore Crops: being a Critical Investigation into th Methods of Measuring Sample Plots, wit special reference to the Liability to Error. B M. D. Chaturvedi. (Oxford Forestry Memoir No. 4.) Pp. xv + 142. (London: Oxford Un versity Press, 1926.) Paper, 10*s*. net; cloth 12*s*. 6*d*. net.

Sylvicultural research is becoming more and mor dependent on observations made in permanen sample plots. These plots are marked out in th forest, treated according to the desired exper mental methods, and the volume of timber standin in them is periodically measured. The value such observations is entirely dependent on th accuracy with which the volume of standing cro can be measured, and even small errors in th measurement of any plot may lead to very fals results. Thus if the volume of a plot increase in five years by 20 per cent., an error of +3 pe cent. in the first measurement and −3 per cen in the second may reduce the increment, a measured, to about 13 per cent. Fair accurac in measurement can be assured if a large numbe of sample trees can be felled for detailed scalin but the felling of numerous sample trees is generall sufficient to upset the sylvicultural experiment i hand.

In order to obviate these difficulties, nearly ever forest research station in Europe has designed i own method of measuring standing timber, and i is claimed that many of these methods give ver considerable accuracy. In the memoir und review, Mr. Chaturvedi has collected together a available records of these methods, and by personal visits to many of the continental research stations he has equipped himself with the latest relevant information. He has subjected the various methods to mathematical analysis, and has applied most of them to the measurement of certain plots in which all the trees were felled to allow of accurate volume determination, by which means he has obtained useful empirical evidence as to their relative reliability.

Mr. Chaturvedi also propounds a new method which aims at combining the good points of several other systems. This method avoids felling any excessive number of trees, and is well worth testing carefully in the field. W. E. H.

Tables of Physical and Chemical Constants; and some Mathematical Functions. By Dr. G. W. C. Kaye and Prof. T. H. Laby. Fifth edition. Pp. vii + 161. (London: Longmans, Green and Co., Ltd., 1926.) 14*s*. net.

SIX years have elapsed since the publication of the fourth edition of these invaluable tables, and it is significant of the change in scientific outlook that the first page of the book is now devoted to atomic numbers and the last to a new table of isotopes. In the list of elements in the order of atomic numbers, three numbers only, 61, 85, and 87, are still unrepresented; the first of these gaps will now be filled by the new element illinium, the isolation of which was reported in NATURE of June 5, 1926, p. 792. New matter has been added on the mechanical equivalent of heat, a subject which Prof. Laby has personally investigated, and the weighted mean of the determinations of Joule's equivalent made since 1880 is given as $4{\cdot}182 \times 10^7$ ergs per 20° calorie on the scale of the hydrogen thermometer.

The reviewer turned eagerly to the value assigned to Planck's constant, h, only to find that the authors have made no attempt to discriminate between the various experimental values quoted. Even the critical discussions by Ladenburg and by Birge are not referred to. The true value is probably very near to Planck's original estimate, $h = 6{\cdot}55 \times 10^{-27}$ erg sec. The same cautious attitude is adopted in the value quoted for the fundamental electron charge, which is given as $e = 4{\cdot}77 \times 10^{-10}$ e.s.u., with a reference to Millikan, July 1917. It may be suggested that in future editions more attention should be paid to spectroscopic constants—even Rydberg's constant does not appear to be mentioned—and other important constants associated with the quantum theory. Scientific workers owe a debt to the authors of this volume, which only those who have attempted to collect such numerical results can fully appreciate. H. S. A.

The Evolution and Development of the Quantum Theory. By N. M. Bligh. Pp. 112. (London: Edward Arnold and Co., 1926.) 9*s*. net.

PROF. MAX PLANCK, whose photograph adorns its frontispiece, contributes a short foreword to this little book. The author sets out with the praiseworthy object of producing a "concise handbook" for the "general scientific reader." In Part 1 he sketches the classical arguments leading to Wien's radiation law and the Raleigh-Jeans law, and describes how their disagreement with each other and with experiment led Planck to his formula and law. Part 2 is a description, which does not profess to be complete, of some applications of the theory; band spectra, for example, are barely mentioned in two sentences. Planck's second hypothesis and a somewhat irrelevant discussion of Nernst's heat theorem, however, fill a whole chapter. The chapters on the light quantum hypothesis, specific heats, and optical spectra, though of necessity brief, are good.

Unfortunately, the author is much at sea in radiation theory and statistical mechanics. Chap. i., his introduction to radiation theory, is so involved that it would be almost unintelligible to any one unfamiliar with the arguments used, and the proof of Wien's displacement law in Chap. ii. is still worse. In Chap. iii., on statistical mechanics, the preliminary explanation is worthless, while the proof of Maxwell's distribution law contains ". . ., let δn be the number of molecules having velocities whose x-components lie between u and $u + \delta u$"; and later, "$\Sigma \delta n = 0$," no distinction being made between that number and its variation. There is a considerable number of mis-statements, such as "A complexion is thus the number of ways in which a particular arrangement can be carried out," and "Now since the mass of the helium nucleus is slightly greater than that of the hydrogen nucleus," and misprints are frequent.

Animal Ecology. By Prof. A. S. Pearse. (McGraw-Hill Publications in the Zoological Sciences.) Pp. ix + 417. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1926.) 20*s*. net.

THE science of animal ecology is relatively new, but a considerable amount of attention has been directed to this aspect of zoology since the beginning of the century. In this development American biologists have played a leading part. We recall Shelford's valuable work on the animal communities in temperate America and Adam's useful guide to the study of ecology in this connexion, both of which gave a tremendous impetus to the study of animals in relation to their environment. Most of our knowledge of the subject is, however, contained in short scattered papers through a vast range of periodical literature or in more specialised works dealing with particular groups.

Some guide to this maze of literature was clearly needed, and Prof. Pearse has rendered conspicuous service in undertaking this task. His book seeks to indicate the scope of the subject and to outline its various sub-divisions. The treatment is of necessity brief, but with the aid of a comprehensive bibliography the reader is directed to fuller details regarding any particular aspect of the subject. The book should serve a useful purpose as a work of reference to university teachers and students in presenting to them a broad and orderly survey of a very large field.

Atmospheric Circulation.

The omission of references seldom leads to intelligibility, and I fear I should have been unable to trace the review mentioned by Prof. W. H. Hobbs (Nature, Dec. 25, p. 915) had Mr. Bonacina not alluded to it in a letter to me. Prof. Hobbs asserts that my result (*Q.J.R. Met. Soc.*, 1926, 85-104) that the prevailing pressures around the poles should be low was explicitly stated by me to refer to an atmosphere circulating symmetrically over a uniform earth and unrestricted by friction. This is not the case. It is true that I worked out the solution of such a problem, but the result I obtained was that, with the highest temperatures over the equator, the pressure would increase all the way to the poles; this is diametrically opposite to Prof. Hobbs's attempted quotation. Prof. Hobbs omits to mention that I went on to examine which of the neglected factors was responsible for the chief difference between theory and observation; that I traced it to friction; and that my final inference of the existence of low pressures about the poles was the result of an argument depending essentially on friction. Incidentally, the despised frictionless theory, if adapted to cooled continents, would be in qualitative agreement with the facts as stated by Prof. Hobbs.

While this matter is under discussion reference must be made to a criticism by Mr. F. J. W. Whipple (*Q.J.R. Met. Soc.*, 1926, p. 333). I showed in my paper that if the prevailing circulation north of a given parallel of latitude is either easterly or westerly, it can be maintained against friction only by interchange of air with lower latitudes. Thinking that I had dynamical grounds for believing that this interchange would, in the conditions of the northern hemisphere, involve mainly south-west and north-east winds, I inferred that the polar circulations must be westerly. Mr. Whipple points out a weakness in the argument, and has led me to modify this conclusion. It seems clear that if there were no horizontal interchange of air, the effect of surface friction would be simply to make the air drift across the isobars until all differences of pressure at sea-level were annulled, and there would be no surface winds anywhere. Somehow this condition is forestalled by the development of irregular winds of cyclonic type, which maintain a continual interchange of air across the mean annual isobars, and the primary effect of such interchange, with an actual distribution of temperature, would probably be a transmission of angular momentum polewards, giving an equatorial belt of easterly winds with broad belts of westerly winds north and south of it. The winds at the southern boundary of the belt of prevailing westerlies in the northern hemisphere must be mainly north-east and south-west; but there seems to be no reason why they should persist all the way to the pole, and if the currents are deflected within this belt so as to become mainly north-west and south-east at its northern margin, they will be capable of maintaining an easterly circulation north of it.

Accordingly I see no great objection to anticyclonic circulations in Arctic and Antarctic regions. The main results that emerge from the discussion are that friction plays a dominating part in atmospheric circulation, and that cyclones are essential to the maintenance of any general circulation and are not disturbances superposed on it. Presumably the distribution of the belts of easterly and westerly winds would be affected by a change in the distribution of temperature in latitude.

Mr. Bonacina's quotation in his review (*Geog. Jour.*, Sept. 1926) expressed correctly the views I held at the time he wrote, but as a result of Mr. Whipple's note I have somewhat modified them in the sense indicated above. The question of the existence of glacial anticyclones strikes me as one to be settled by observation. I would only point out that the great majority of the observations quoted on the point are irrelevant. They refer to stations near the coast, where permanent outflowing antitriptic winds are to be expected whatever the winds in the interior of the continent may be. To infer an anticyclonic circulation over a glaciated continent on the basis of winds from the land at coastal stations is like finding out whether it is raining by turning the tap on. The observations in the interior of Greenland and Antarctica by Koch, de Quervain, and Scott, quoted by Prof. Hobbs in his book, are to the point, but none of the others are.

Harold Jeffreys.

The Significance of Phosphorus in Muscular Contraction.

An examination of the very extensive literature dealing with the function of phosphorus compounds in the chemical mechanism of muscular contraction reveals so many contradictory statements that it is evident that the technique in use must be subject to some serious fault. Since we have found what is probably the main cause of the discrepant results obtained in this field, it seems desirable to communicate our results without delay.

There appears to be in muscle tissue an organic phosphorus compound which, by reason of its great instability in acid solution, has been confused hitherto with inorganic phosphate, to which it gives rise in the course of the estimation of inorganic phosphates by the methods of Embden or of Briggs, or by any method involving the use of mineral acid. The confusion is increased by the fact that this substance, the organic phosphorus compound which we have designated 'phosphagen,' is intimately connected with the chemical mechanism of contraction; the estimation, therefore, of 'inorganic' phosphate by the above methods is hopelessly misleading, since by them one measures the sum total of two substances which vary independently in amount. It is possible, by avoiding the use of acid solutions, to estimate true inorganic phosphate, since 'phosphagen' appears to be stable in neutral or slightly alkaline solution. The following table, which concerns the gastrocnemius muscle of the frog, illustrates the changes in the amount of phosphate and 'phosphagen' in a muscle subjected to different treatments:

	Resting.	Rapidly Fatigued.	Heat Rigor.	Incubation in $NaHCO_3$.	
				Without NaF.	With NaF.
Inorganic phosphate . .	20	50	90	110	20
'Phosphagen'	65	25	0	0	0
Sum total .	85	75	90	110	20

The figures are given as milligrams of phosphorus per 100 gm. of muscle, and are representative of a number of experiments. The third row of figures corresponds to the 'inorganic' phosphate as estimated by the ordinary methods.

These facts suffice to explain many of the anomalies to be found in the literature. We will deal here with only one of these. Embden and his co-workers have noted a disappearance of inorganic phosphate in a suspension of minced muscle in sodium fluoride solution. They have attributed this to a synthetic action of the fluoride ion. Comparing the first and last columns in the above table there is an apparent synthesis of 65 mgm. of 'inorganic' phosphate into something not estimated by the Embden technique. The real state of affairs, however, seems to be that the true inorganic phosphate is not affected at all. Either the fluoride ion catalyses the conversion of 'phosphagen' into some acid-stable compound, or else it poisons a catalyst which normally causes its transformation into inorganic phosphate. Rapidly induced fatigue produces a similar but smaller effect.

One further point of interest worthy of note here is that while unstriated muscle contains about the same amount of genuine inorganic phosphate as does striated (skeletal) muscle, it appears to contain no 'phosphagen.' The heart muscle of the frog also gives about 20 mgm. of inorganic phosphorus per 100 gm. of muscle, together with a slight but definite amount of 'phosphagen.' One is tempted to correlate the 'phosphagen' content of a muscle in its resting condition with its ability to respond to sudden demands for violent activity.

Whilst we have at present no definite knowledge of the nature of this substance, it seems quite possible that it may be the unstable ('active') hexose monophosphate, the existence of which was inferred by Meyerhof in interpreting the phenomena of glycolysis in cell-free muscle extracts, and the fermentation of sugar by yeast.

Effect of a Large Number of Receiving Aerials on the Propagation of Wireless Waves.

In connexion with some experiments, I was led recently to estimate the extent to which a large number of receiving aerials would contribute to the absorbing effect of the earth's surface on wireless waves in resonance with them. A short calculation showed that, with a density of aerial distribution such as now exists in an urban district surrounding a local broadcasting station, the energy absorbed by the aerials should be the decisive factor in determining the surface attenuation. Since the aerials would naturally only effect those waves which were very close to wave-lengths to which they were tuned, it was not difficult to test this conclusion. A number of experiments have been made on the general principle of measuring the intensity of waves which have travelled across a considerable area containing large numbers of broadcasting aerials, the wave-length being gradually varied from just below to just above the normal wave-length of the local broadcasting station (2 LO) to which the majority of the aerials may be assumed to be tuned (that is, a wave-length of 364 metres).

These experiments, which were carried out with the assistance of Dr. Smith-Rose and Mr. Munro, with the kind co-operation of the B.B.C., have yielded results that constitute very definite evidence of a critical effect of large magnitude occurring at or near the resonant wave-length, and the phenomenon appears only ascribable to the selective action of the multiplicity of tuned aerials in the path of the waves. Thus, at Slough (see Fig. 1), when receiving from the 2 LO transmitter at Marconi House, an increase in intensity of the order of 90 per cent. was observed for a variation in wave-length of only 5 per cent.; while it will be seen that for a wave-length change of 120 metres a total increase of field strength of nearly five to one was obtained; that is, for a given power transmitted, the received power increased more than twenty-fold.

Now the hypothesis that this effect is mainly due to the transmitted waves passing in and out of resonance with the aerials in their path is confirmed by the fact that the effect was found to increase in proportion to the distance which the waves travelled over crowded residential districts, and was negligible when the wave path lay almost entirely over open country with only a small residential area round the transmitter. The hypothesis was further confirmed by the fact that the effect was shown not to be peculiar to a given transmitter or receiving site. On the other hand, it seems at first to be contradicted by the fact that the minimum intensity, and therefore apparently the maximum absorption, does not occur at the resonant wave-length but at a wave-length considerably below. In some cases the minimum had not been reached at 300 metres, below which wave-length experiments have not yet been carried. A brief study of the theoretical side of the problem, however, shows that this is not necessarily the case. If an electromagnetic wave is propagated in a medium containing resonators of all one periodicity, it is well known that, on varying the wave-length of the waves in the neighbourhood of the resonant value, there is a critical change in the medium, not only of its absorption factor but also of its refractive index, the latter being responsible for the optical phenomenon of anomalous or selective dispersion.

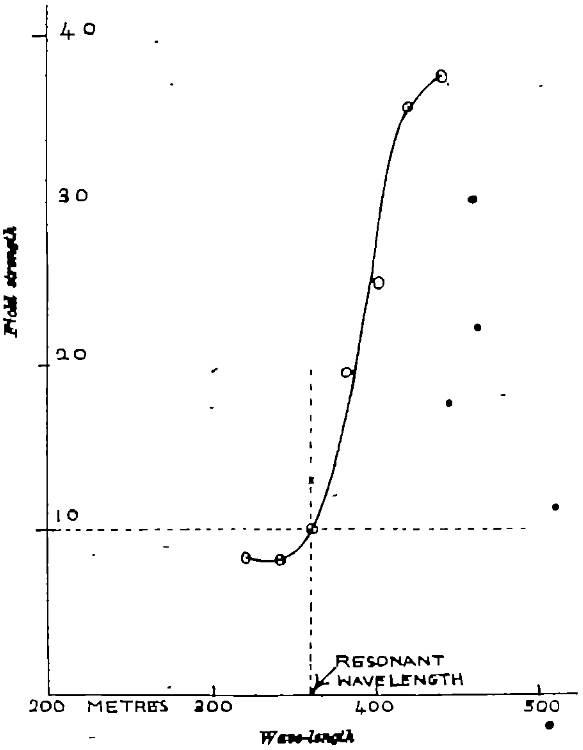

Fig. 1.—Effect of wave-length change on received field strength. Transmitter—2 LO. Receiver—Slough.

Now there is an undoubted analogy between this and the experiments under discussion. The medium containing resonators is in this case the layer immediately above the earth's surface containing the tuned aerials. We must, therefore, take into account the possible effect of a change in the refractive index of this medium as well as in its absorption factor. But the theory of wireless wave propagation as developed by Sommerfeld and others shows that the former factor may be as important as the latter in determining the attenuation which the waves will experience in passing over the earth's surface. Finally, the theory also shows that a variation of the refractive index with the wave-length in the manner demonstrated in theoretical and experimental optics in such circumstances (anomalous dispersion) would have a tendency to cause the point of maximum attenuation (and therefore minimum received intensity) to be shifted to the left of the critical wave-length line, as it was found to be from observation. This is manifestly only a tentative explanation, but it is enough to show that this unexpected feature in the experimental results does not invalidate the general conclusion that the large number of receiving aerials in the London area have a very marked absorbing effect on the waves passing over them.

The observations on which the above note is based were carried out as part of an investigation for the Radio Research Board of the Department of Scientific and Industrial Research.

Relation between the Reciprocal Impenetrability of Matter and Pauli's Exclusion Principle.

When the collisions between the molecules of an ideal gas are taken into consideration, then the motion of the gas does not appear to be multiply periodic. It is therefore impossible to quantise this motion by means of the 'classical' quantum theory. Moreover, in the treatment of the ideal gas by means of the new 'undulatory mechanics,' hitherto only the impenetrability of the walls of the vessel has been taken into account, and not the reciprocal impenetrability of the molecules (E. Schrödinger, *Phys. Zs.*, 27, 95, 1926). I propose to show here that, in the case of impenetrable moving *mass-points*, wave-mechanics gives an exact and very elementary solution. Simultaneously we arrive at the relation mentioned in the title.

For purposes of brevity we will limit ourselves to a 'one-dimensional' gas: N monatomic mass-points of equal mass M are enclosed in a tube, which extends from $x = -\frac{\pi}{2}$ to $x = +\frac{\pi}{2}$. If we first take into account only the impenetrability of the ends of the tube, then we have to look for all the solutions of the N-dimensional Schrodinger-equation:

$$\left[\frac{\partial^2}{\partial x_1^2} + \frac{\partial^2}{\partial x_2^2} + \ldots + \frac{\partial^2}{\partial x_N^2} + \frac{8\pi^2 M}{h^2}E\right]\psi = 0, \qquad (1)$$

which are equal to zero at the faces of the N-dimensional $\pm\frac{\pi}{2}$-cube. These solutions are:

$$\psi = \cos a_1x_1 \cos a_2x_2 \ldots \cos a_Nx_N, \qquad (2)$$

where $a_1 \ldots a_N$ are arbitrary positive integers and where $E = \frac{h^2}{8\pi^2 M}(a_1^2 + \ldots a^2_N)$. To the same E, and with the same numbers $a_1 \ldots a_N$, there belong also all the solutions obtained from solution (2) by exchanging all the co-ordinates $x_1 \ldots x_N$ with each other, at the same time keeping the numbers $a_1 \ldots a_N$ fixed. By multiplication of all these solutions by arbitrary constants and addition, we obtain the most general solution of this kind:

$$\Psi = \Sigma C(p_1 \ldots p_N) \cos a_1x_{p_1} \cos a_2x_{p_2} \ldots \cos a_Nx_{p_N}, \qquad (3)$$

where $p_1 \ldots p_N$ signifies *one* permutation of the numbers $1 \ldots N$, and the summation must be taken over *all* the permutations.

Now let us also consider the reciprocal impenetrability of the molecules. That can be done by means of the additional 'diagonal-restriction'; which in wave-mechanics corresponds to the impossibility of two molecules occupying the same point in space at the same time. Of all the solutions of the form (3), only those are allowed which are *also* equal to zero at all points of the $\frac{N(N-1)}{2}$ flat 'diagonal-spaces' of $N-1$ dimensions which are represented by the equations $x_h = x_k (h, k = 1, \ldots N)$. It can be shown now best by considering first the cases $N=2$ and $N=3$ that all the constants $C(p_1 \ldots p_N)$ must have values equal to each other or opposite in sign, according as the arguments $p_1 \ldots p_N$ are derived from the numbers $1 \ldots N$ by an even or an odd number of simple permutations. Or, in other words, ***because of the reciprocal impenetrability of the molecules*** only the ***antisymmetric*** solutions are allowed:

$$\Psi^{\text{antisym}}(x_1 \ldots x_N) = C \cdot \begin{vmatrix} \cos a_1x_1 & \ldots & \cos a_1x_N \\ \vdots & & \vdots \\ \cos a_Nx_1 & \ldots & \cos a_Nx_N \end{vmatrix}. \qquad (4)$$

Thus, just those solutions which, according to the researches of Heisenberg and Dirac, are connected with Pauli's exclusion principle (the exclusion of equal quantum numbers for two electrons in the same atom—in our case for two gas molecules in the same vessel), the determinant becomes identically equal to zero when two of the numbers a_s are equal to each other.

Finally, we may remark as follows:

I. For a three-dimensional gas contained in a vessel of *general* form, naturally $\psi_{\alpha\beta\gamma}(xyz)$ must be substituted for $\sin ax$; further, in the 'diagonal-restriction' the equations $(x_h - x_k)^2 + (y_h - y_k)^2 + (z_h - z_k)^2 = 0$ for $x_h = x_k$, and we have always to exchange a triplet $x_hy_hz_h$ with a triplet $x_ky_kz_k$.

II. In order to show that the impenetrability of the walls and for the molecules must really be expressed by the corresponding zero-conditions of the solutions of the Schrödinger equation, we approximate first this impenetrability by continuously varying forces of repulsion and then we go in the resulting solutions to the limit.

III. At the same time we get very simple models for the treatment of the question of how far the Pauli's exclusion principle holds for two electrons if they are in the same atom but not if they belong to distinctly separated atoms.

IV. The non-validity of Pauli's principle for 'light-corpuscles' should now perhaps be connected with their reciprocal *penetrability*, though the very provisional and symbolical character on one hand of the light corpuscles, and on the other of the multi-dimensional wave-equation (1), should specially be remembered here. These remarks and some connected statistical questions will be dealt with elsewhere.

The Imperial Forestry Institute.

SOME comment is called for on the note on the Imperial Forestry Institute which appeared in NATURE of Jan. 15, p. 96, and which is likely to produce a wrong impression in the minds of those unacquainted with the facts. With reference to a proposal to spend a sum of £75,000 on the erection of new buildings to accommodate the Imperial Forestry Institute at Oxford, the following observation is made: "On the face of it the scheme appears to be a laudable one. Nevertheless, it would seem to demand further careful consideration if this money or the bulk of it is to be provided from the Treasury." As there has been no suggestion that the Treasury should make any contribution towards the scheme, the fears expressed in regard to national expenditure may in this instance be set at rest.

The note concludes with the following passage: "Two points appear to demand a public and unbiassed inquiry before the Government is committed to the scheme; they are: (1) Are not the existing schools of forestry capable of giving all the education required, both up to the degree and post-graduate, and to undertake research? (2) Is it advisable to shut up forestry education in a water-tight compartment?" The writer is apparently not aware that such an inquiry was carried out a few years ago by an Interdepartmental Committee on Imperial Forestry Education, which issued in 1921 a report published as Command Paper 1166. In this report both the above questions are definitely answered in the negative. In proposing the establishment of a central institution for higher training and research in forestry, the Committee made it clear that there was no intention of interfering with the work done by university schools of forestry, and provided the training of these was maintained at a required standard, it recommended that selected students from these schools should be eligible for admission to the central institution. The Committee may be presumed to have conducted its inquiries in an impartial manner; it visited the universities of Oxford, Cambridge, Bangor, and Edinburgh, and also took evidence from other universities, as well as from institutions and societies interested in forestry, and in selecting Oxford as the site of the future forestry institute we may assume that it selected that place which it considered most suitable for the end in view.

Apart from the Interdepartmental Committee, the question was carefully considered by two separate Empire Forestry Conferences, one held in London in 1920 and the other in Canada in 1923. At both conferences the inadequacy of the existing arrangements for higher training and research in forestry was commented on, and the necessity for establishing a central institution for the needs of forestry in the British Empire was urged. The Interdepartmental Committee's recommendations were endorsed by the second Empire Forestry Conference and also by the Imperial Economic Conference held in London in 1923. The Imperial Forestry Institute was accordingly established at Oxford and started work in October 1924. Should any readers of NATURE be interested in the progress actually made so far, I shall be pleased to send them a copy of the second annual report.

R. S. TROUP.

Imperial Forestry Institute,
Oxford, Jan. 19.

IF under "Treasury" Prof. Troup includes the Colonial Office and Forestry Commission (the latter two offices defraying the bulk of the expenses of the Institute at present), the tax-payer, whether in Britain or overseas, will be relieved to have the assurance.

Prof. Troup's somewhat *ex parte* account of the proceedings leading up to the inauguration of the Institute in 1924 has in one form or another appeared on several occasions in the Press. He does not, however, appear to realise that a growing body of scientific opinion is at the back of the representations which the authorities of the Universities of Cambridge and Edinburgh placed before the Secretary of State for the Colonies and members of the Forestry Commission on the subject of the concentration of (State-subsidised) post-graduate forestry work of all kinds at one university. The authorities of the two universities stated quite definitely that they had no intention of giving up the post-graduate courses they had already inaugurated, and all they asked for was an 'open door.' It is understood that the Secretary of State accorded a sympathetic hearing, and intimated that whilst nothing could be done at the moment, the experiment was only made for a five-year period and would be open to a reconsideration at the end of the period.

THE WRITER OF THE NOTE.

Ionisation in Hydrogen Chloride Vapour.

BEFORE a meeting of the American Physical Society in April 1925, I reported some preliminary results of an investigation of ionisation by electron impact in hydrogen chloride vapour at low pressures, using the familiar method of mass spectrum analysis to identify the ions produced. I had observed in large numbers both positive and negative ions of which the ratio of mass to charge was about 36 times that of the hydrogen nucleus. At relatively high pressures I had also detected positive ions of *m/e* about 72 times the same unit. At all pressures the ions H^+, H_2^+, and $(H_2O)^+$ had been present, although in general there were fewer of these than of the other types.

Since then the study has been extended, using a new apparatus of higher resolving power. The ions at '36' were resolved into four separate types of positive ion, namely: $(Cl^{35})^+$, $(HCl^{35})^+$, $(Cl^{37})^+$, and $(HCl^{37})^+$; and only two types of negative ion, presumably $(Cl^{35})^-$ and $(Cl^{37})^-$. The ratios $(Cl^{35})^+/(Cl^{37})^+$, $(HCl^{35})^+/(HCl^{37})^+$, and $(Cl^{35})^-/(Cl^{37})^-$ were equal, within the limits of error, to the computed abundancy ratio of the isotopes based on the atomic weight of chlorine. The heavier ions previously mentioned were not observed at the lower pressures necessarily used in the new apparatus, and therefore could not be precisely identified.

Comparisons of the relative numbers of the different ions under many different conditions of pressure, energy of striking electrons, etc., have led to the conclusion that the only type of ion produced by an impact of an electron of between 4 and 75 volts energy on a hydrogen chloride molecule is $(HCl)^+$. This is the type of ion to which corresponds the ionisation potential of about 13·8 volts observed by others.

A widely held conception of ionisation by impact in hydrogen chloride assumes that the primary process consists of the formation of H^+ and Cl^- ions. The conclusion reached in these experiments is contrary to this assumption, though it was difficult to disprove the possibility, since both H^+ and Cl^- ions were produced. However, (1) it was observed that at low pressures there were always more H_2^+ ions than H^+; (2) neither of these showed any reproducible quantitative relationship to the $(HCl)^+$ ions; (3) their number was always small compared with the latter, except when the apparatus had been evacuated only recently; and (4) they diminished and *finally disappeared* with time, as the apparatus stood for days continuously evacuated.

These results and others led to the conclusion that the hydrogen ions came not from HCl molecules but from H_2 molecules formed probably by some process requiring the presence of the hot filament and of water vapour given off by the walls of the tube. Furthermore, the arrangement of the electrodes and fields in the tube permitted the discovery that the Cl^- ions observed came from close to the filament and that none came from any region in which electrons of more than three or four volts energy were available for impact. It thus seems possible not only to account for the existence of the H^+ and Cl^- ions but also to eliminate them definitely as the products of inelastic electron impacts of 13·8 or more volts with HCl molecules.

A detailed report of the experiments is being prepared for publication.

A New Pressure-Temperature Formula for Vapours.

ABOUT forty formulæ have been proposed to represent the relation between the pressure p and temperature t of saturated vapours. The suggested formulæ reproduce the experimental results only on a limited part of the vapour-pressure curve, and not on the whole of it. Many of them give inexact results at very low temperatures or in the proximity of the critical point. Finally, none of them reproduces the critical point as the singular point (end-point, *le point d'arrêt*) of the pressure-temperature curve.

I have succeeded in finding a formula which satisfies all the claims both in respect to precision and in respect to correct reproduction of the conditions on the limits.

The formula may be written as follows:

$$t+c=k\left(\sqrt[4]{p}-10^{\alpha-\frac{\beta}{\log p_k-\log p}}\right), \quad . \quad . \quad (1)$$

where p_k is the critical pressure, and c, k, α, β are constants, different for different substances.

At pressures p sufficiently high (for ordinary liquids, throughout the range from 1 - 3 atmospheres up to the critical pressure), the difference $\log p_k - \log p$ is small. The exponent $\alpha-\frac{\beta}{\log p_k-\log p}$ is therefore a negative number with a large absolute value, so that the exponential term practically does not differ from zero. The formula thus becomes simply

$$t+c=k\sqrt[4]{p}. \quad . \quad . \quad . \quad . \quad (2)$$

Such a linear relation between t and $\sqrt[4]{p}$ was found in 1883 by Jarolimek.

At $p=p_k$, t, as given by the formula (1), changes discontinuously; thus the formula reproduces the critical point. When p is extremely small (therefore at very low temperatures) the term $\sqrt[4]{p}$ disappears in comparison with the exponential term, and the formula becomes

$$\log p=\log p_k-\frac{\beta}{\alpha-\log\left(-\frac{t+c}{k}\right)}. \quad . \quad (3)$$

Formula (1) represents with sufficient accuracy the experimental data for the most varied substances; for example, for liquid metals (also for mercury in the whole explored interval from 0° to 880°), for organic liquids studied by S. Young, and for permanent gases.

The constant c has usually the values lying between 0 and 273. Helium shows a remarkable peculiarity: it has $c=273$; thus, for helium the fourth root of the vapour pressure, in virtue of formula (2), appears to be approximately proportional to the absolute temperature.

Water, as usual, shows an anomaly: the index of the root is here 13/3 instead of 4.

A detailed account will be published in one of the physical journals.

'Hard Seeds' in Leguminosæ.

IT may be of interest to Mr. Alexander Nelson and to other readers of NATURE (Dec. 4, 1926, p. 804) to know that sulphuric acid has been used industrially for the promotion of germination in hard leguminous seeds for some years. The substitution on an extensive scale of *Indigofera arrecta* for the previously cultivated *Indigofera sumatrana* by the indigo planters of Bihar during the early years of the century was, in fact, made possible largely by the introduction of the sulphuric acid method of seed treatment into their agricultural practice. The seed of *Indigofera arrecta* grown in Bihar was found to possess a very hard coat and to fail to germinate almost entirely under the conditions of soil moisture prevailing in northern India. Treatment with sulphuric acid led to perfect germination in a well-ripened sample of seed, and the method was used for many years and is, I believe, still used by the Bihar planters. The procedure differs slightly, however, from that indicated by Mr. Nelson in that concentrated, instead of dilute, acid is employed. A full description of the method as used in Bihar may be found in my report to the Bihar Indigo Planters' Association for the year 1906–7.

I reported the successful application of the procedure to other hard seeds, those of a series of fibre-yielding jungle plants not exclusively Leguminosæ, in collaboration with R. S. Finlow in the *Proceedings of the Asiatic Society of Bengal* (New Series, vol. 3, No. 10) in 1907. Some of these seeds withstood the action of the concentrated acid for surprisingly long periods and germinated satisfactorily after it.

In the same year a paper in which an attempt was made to explain the cause of hardness in the seeds of *Indigofera arrecta* was published by D. L. Day and myself (*Annals of Botany*, vol. 21, No. 81). Our findings, as regards hardness being due to a surface deposition on the seed-coat, were in accordance with those of Mr. Nelson; we were, however, unable to determine the precise nature of the coating. Information on this point will be most interesting.

Television.

As Mr. J. L. Baird, in NATURE of Jan. 29, mentions my name in connexion with 'television,' it may be of interest if I give a brief résumé of the demonstrations Mr. Baird has given to me at Motograph House. Last June he gave a demonstration of the transmission of the images of living people, showing gradations of light, shade, and detail. An account of this demonstration was published in NATURE of July 3.

The images, naturally, were not comparable with those shown on a modern cinema screen, but the likenesses were unmistakable. The person whose image was transmitted sat in a flood of brilliant light. Mr. Baird has now developed a method by which the image of the person is transmitted although he is in complete darkness. This result is obtained by flooding the 'sending' room by infra-red rays. On Nov. 23 last, Mr. Baird gave a demonstration to Mr. W. R. Crookes and me. One of us stayed in the sending-room with a laboratory assistant in apparently complete darkness. In the receiving-room, on another floor, the image of the assistant's head was shown brilliantly illuminated on a screen, and all the motions he made could be readily followed.

These images were not outlines or shadowgraphs, but real images by diffusely reflected rays. The application of these rays to television enables us to see what is going on in a room which is apparently in complete darkness. So far as I know, this achievement has never been done before.

We had the impression that the image on the screen was not quite so clearly defined as when visible rays were used, but we easily recognised the figures we saw, and made out their actions. The direct application of Mr. Baird's invention in warfare to locating objects apparently in the dark seems highly probable, but I hope that useful peace applications will soon be found for it.

Alexander Russell.

Jan. 28.

Relativity and the Observer.

In Mr. Bertrand Russell's article in the new volumes of the "Encyclopædia Britannica" entitled "Relativity: Philosophical Consequences," there occurs the following sentence: "The 'observer' who is often mentioned in expositions of relativity need not be a mind, but may be a photographic plate or any kind of recording instrument." I should like to know how far Mr. Russell can claim to be in agreement with physicists on this point. For my own part it would seem to make complete nonsense of the theory. As I understand the principle of relativity, every object which can be observed, including the measuring rods and clocks which are used to observe, not excepting the retina of the observer's eye, undergoes transformation when the observer passes from one system of reference to another. If it is not so, if there be one piece of matter which can claim to be privileged, be it only a single electron, what, I ask, is the use or meaning of the principle ?

However, I propose a simple test. Will Mr. Russell —and any one who thinks he is right—read the article by Mr. J. H. Jeans on "Relativity" which immediately precedes his own article, and wherever he finds the word observer, make the substitution "photographic plate or any kind of recording instrument," and see if he can make sense of the principle.

I agree that the observer need not be a mind if by mind is meant anything over and above the simple spiritual or ideal act of observing, but the observer most certainly cannot be the observer's body or a part of his body or the instrument he uses, for no particle of such material structure possesses any privilege in the physical world. Surely if it did the principle of relativity would be superfluous, for the privileged object would itself provide an absolute system of reference.

The Continuity of Existence.

Recently, in an address to the British Academy, Prof. T. Percy Nunn propounded the idea that the existence of an electron is not necessarily continuous, and that when an electron revolving in an orbit about a nucleus changes to another orbit, it is possible that the electron goes out of existence in the first orbit and comes again into existence in the second orbit. It is of interest that Planck's theory that action is not a continuous entity but consists of discrete quanta leads to a similar conclusion.

A point of our ordinary space has in Einstein's fourfold world a record that is called its world line. As a bundle of energy such as an atom or electron or nucleus has extension, it is appropriate to call its record in the fourfold its world-filament. Since energy integrated through an interval of time is action, this filament of the atom is action; and the atom or energy is the section in which our space cuts the filament.

In this picture action is represented as a continuous filament. This representation contradicts Planck's theory, and the picture must be amended in order to conform. The filament must be replaced by a series of quanta dotted along a line.

Consider now what happens as our space travels through the fourfold world. In some positions it will intersect a quantum of the series dotted along the line; in other positions it will miss. The atom or bundle of energy, being the intersection of the action by our space, will exist when our space intersects a quantum, and will not exist when there is no intersection with a quantum. In other words, as our space travels through the fourfold (that is to say, as time passes) the atom or bundle of energy keeps flashing into existence and out again.

D. B. Mair.

Double-Image Effect in Transparent Microscopic Spheres.

In a paper published by us in the current number of the *Proc. Roy. Soc.* on the "Scattering of Light by Individual Particles in Smoke," we have directed attention to a double image effect exhibited by transparent microscopic spheres. As a result of further experiments we have found that the explanation of the effect given requires some modification. One of the images is due to reflection from the surface of the sphere instead of to internal reflection. As was suggested to us by Prof. Tyndall, this can be seen by placing a small bulb containing a gold sol in the beam of light from an arc, when one image is coloured red and may be seen to be due to refraction through the sol, whilst the other is white and is produced by reflection from the surface of the sphere.

R. Whytlaw-Gray.

Helium or Helion ?

May I invite the opinion of readers of Nature as to the desirability of changing the name of element No. 2 from helium to helion ? This element was christened at a time (1868) when its existence was recognised on the strength of the D_3 line in the chromosphere, and when, in view of the proximity of this line to the D lines of sodium, it appeared not improbable that it was a metal. Now that helium has been isolated, liquefied, and even solidified, we know that it is typically non-metallic, exactly like argon and the other inert gases discovered in later years, and now placed in group 0 of the Periodic System. Its present name, therefore, is anomalous.

Birmingham, Dec. 9.

Changes in the Length of the Day.

By Prof. Ernest W. Brown, F.R.S.

At the present moment the answer to the question as to whether the rate of rotation of the earth is fluctuating, depends almost wholly on the interpretation which shall be given to certain differences between the observed positions of two or three bodies in the solar system and their positions as calculated from the laws of motion and gravitation. Owing to the unavoidable errors of observation, usually greater in the past than now, a detailed discussion of the astronomical data is necessary in order to discover, if possible, the extent to which the astronomical evidence is reliable. To me it has appeared to be sufficiently good to warrant full consideration of its consequences and to suggest further search for confirmation of the results.

Although these fluctuations appear to be physically independent of the well-known progressive change due to tidal friction, the latter is included with the former in the astronomical observations, and this fact requires a knowledge of the amount of the progressive change in order to isolate the fluctuations.

The progressive change is mainly determined from a comparison of material deduced from ancient eclipses with modern observations. Dr. J. K. Fotheringham's latest determination of the frictional portion gives an amount the cumulative effect of which at the end of a century is to change the apparent longitude of the moon by 4″·5; since it varies as the square of the time, the accumulation in a decade is less than a twentieth of a second of arc. An apparent displacement of the sun of the same character had been deduced earlier by Dr. P. H. Cowell; for this Dr. Fotheringham gets a century accumulation of 1″·5, but states that any values between 1″·1 and 1″·7 will satisfy the observational material.

The hypothesis that these amounts were due to tidal friction was first placed on a numerical basis by Prof. G. I. Taylor, who showed that shallow seas must be mainly responsible, and that, in particular, the Irish Sea produced about one-fiftieth of the observed amount. Shortly after, Dr. H. Jeffreys, from such data on tides, currents, and ocean depths as were available, deduced in the same manner from all the shallow seas of the globe an amount not very far from that obtained by astronomical observation; in fact, the two values agreed well within the errors due to the uncertainty of the data.

The apparent solar effect bears, however, a relation to the apparent lunar effect, which depends mainly on the amounts of the friction which are to be attributed to the solar and lunar tides respectively. Jeffreys showed that if we accept Fotheringham's figure for the apparent lunar effect, the maximum apparent solar effect in a century, namely, 0″·9, is obtained when we attribute all the friction to the lunar tides. This is somewhat less than the least figure, 1″·1, admitted by Fotheringham.

While the discrepancy exists and is in need of explanation, too much stress should not be placed upon it in view of the uncertainty of much of the material used to deduce the results. The hypothesis of continental drift has some bearing on the question. Practically the whole of the ancient astronomical observations were made in a restricted area on the earth's surface. If this region had drifted relatively to the rest of the earth in the direction opposite to the tidal drift, that is, east, by a sensible fraction of the total tidal retardation, the discrepancy would disappear. In this sense the drift could scarcely be tidal; if its existence be postulated, an internal source seems to be necessary.

In extrapolating these results into the past or future, it is to be remembered that the astronomical observations cover less than 4000 years, while the frictional calculations depend only on modern data. The discussion of the latter by Jeffreys showed that two-thirds of the whole amount was due to the Bering Sea alone. This sea is bordered on the south by the Aleutian Islands, which now constitute a region of considerable seismic and volcanic activity. From what we know of changes of ocean depth in such regions, there is no security that changes in the depth of this sea may not have taken place, even within historic times, sufficient to modify sensibly the total amount of tidal friction. While a retardation of the rate of rotation by tidal friction has certainly existed throughout the geologic history of the earth, its amount has probably been subject to considerable variations, and the same may be said of the future.

The results contribute nothing to a hypothesis which demands a sliding of the crust as a whole over the nucleus if the assumed angular velocity of relative shift be constant. While a retarded or accelerated effect is not excluded, the substantial agreement of the observed and computed friction indicates that it is probably, if existent, quite small. The same reasoning can be applied to other frictional effects; for example, that of an assumed general average circulation of the atmosphere relative to the earth's surface.

We now come to the fluctuations in the earth's rate of rotation which are indicated by the astronomical evidence. There are accelerations and retardations of an order of magnitude quite different from that of the frictional effect. There have been decades in which the accumulated apparent change from uniform motion has been several seconds of arc, while that due to friction in similar periods is less than one-twentieth of a second, as pointed out above. Since the frictional effect has always the same sign, while these fluctuations have both signs, they cannot be due to variations in the amount of friction, or indeed to any frictional effect caused by attractions of bodies outside the earth. Before discussing their origin further, however, I shall give some indication of the evidence on which their existence is postulated.

Briefly stated, the astronomical evidence comes mainly from a comparison of the deviations of the moon and sun from their gravitational orbits, with confirmatory evidence from the transits of Mercury. The earth is the clock by means of which the rates of motion of these bodies are measured. If the rate of the clock varies, the apparent changes in the rates of motion of other bodies will be substantially proportional to the rates themselves. The best test of the clock is the fastest moving body which has been sufficiently observed, namely, the moon. The latter exhibits apparent variations which are much too large to be attributed to defects either in the observations or in the gravitational theory. When we examine the observations of the sun, after applying all known corrections, including the secular acceleration, we find a similar set of variations of the right order of magnitude. But as the angular motion of the sun is less than 1/13 that of the moon, the variations are less in this proportion, and consequently are observable with a corresponding degree of uncertainty. In fact, it is only by combining all the existing material that we can feel any degree of confidence in their existence.

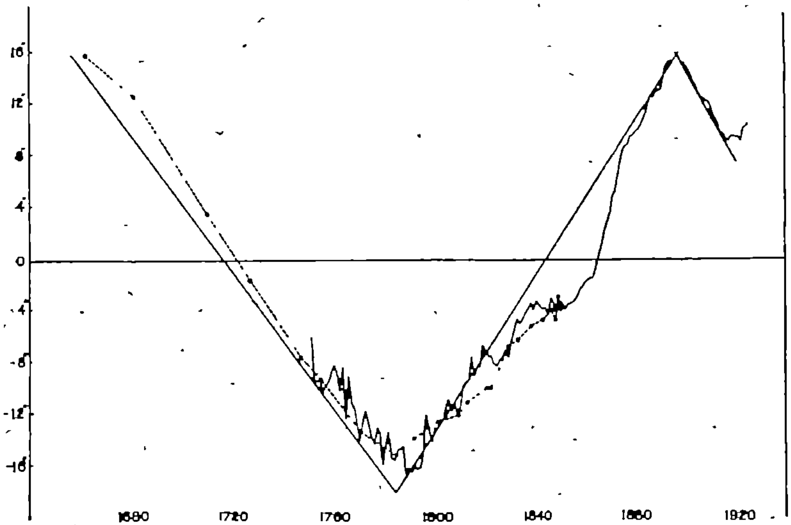

FIG. 1.—Fluctuations of the moon's mean longitude from Greenwich meridian observations (full line), and from occultations (broken line). The inclined straight lines are guides for the eye.

While the motion of Mercury round the sun is four times as fast as that of the earth, the relative lack of observational material more than offsets the advantage gained by the speed of motion. Nevertheless, the valuable work done by Mr. R. T. A. Innes in discussing these observations, the results of which led him to revive Newcomb's original hypothesis, constitutes an important addition to the evidence furnished by the moon and sun.

Fig. 1 exhibits the deviations of the moon in longitude from its gravitational orbit (which latter includes the frictional effect) as judged by the Greenwich meridian observations (full line) and the occultations (broken line); the inclined straight lines are merely guides for the eye. After 1850, the two sets and other observations so nearly agree on the scale of this figure that the Greenwich material is alone shown. The main outlines of the fluctuations with a minimum near 1790, a maximum close to 1898, and a marked change near 1917, are evident. Details before 1850, and in particular between 1810 and 1850, are doubtful; it seems that one set was subject to systematic errors which lasted for many years.

Fig. 2 shows (full line) the corresponding deviations of the sun as obtained from Greenwich, on a much smaller scale; the broken line is the full line curve of Fig. 1 with each ordinate divided by 13·3—the ratio to be used for the hypothesis of a change in the earth's rate of rotation. The coincident changes about 1898, 1917, are well marked; that at 1790 is doubtful, on account of the large deviations which follow this date. Comparison with observations from other places appears to indicate defects in the Greenwich material for the sun in this period, and, judging by the occultations, for the moon also. The same comparison indicates systematic errors of observation throughout the whole range which, while not large enough to change the principal correlations, are large enough to account for the differences between the second halves of the curve in Fig. 2.

The evidence thus favours the hypothesis of changes in the earth's rate of rotation rather than that of unknown forces affecting the motions of the bodies in this particular manner. If it be adopted, it is easy to prove that, owing to the nearly spherical distribution of the earth's mass, the causes of the change must almost certainly be internal. Since the angular momentum of the earth remains constant, we are reduced to the consideration of changes in the distribution of its mass, with respect to the axis of rotation. An idea of the magnitudes involved can be obtained from the supposition that

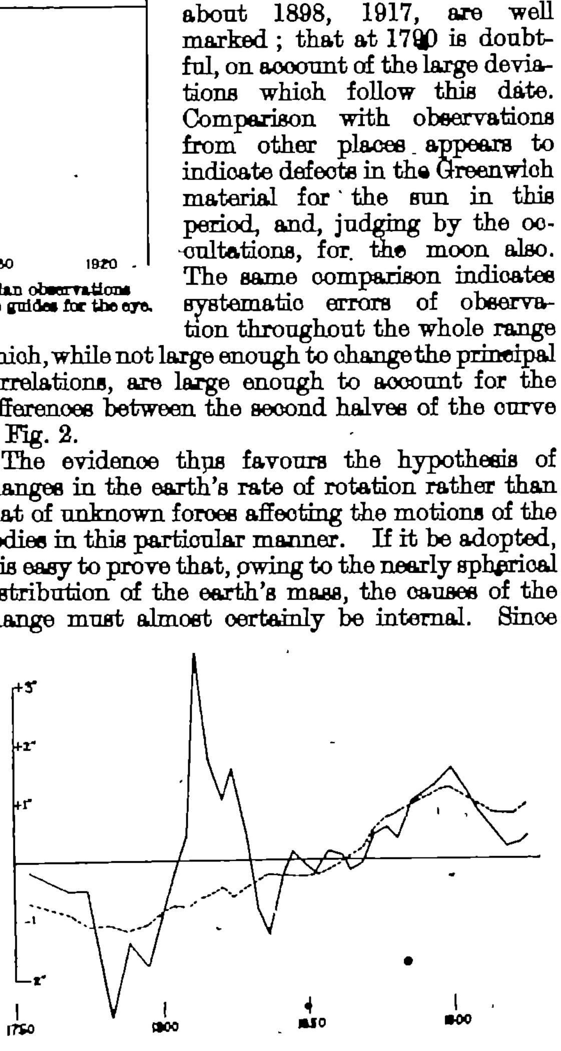

FIG 2.—Full line curve: Greenwich tabular minus observed errors of the sun, including the secular acceleration. Broken line: 1/13·3 of the lunar fluctuations.

the effects are due to successive raising and lowering of the whole crust. If the maximum change of the outer radius be twelve feet, the thickness of the crust which must be moved vertically by this amount, in order to explain the astronomical observations, is fifty miles. If uniform expansions and contractions throughout the whole earth be assumed, the maximum change of the external radius necessary is five inches. An assumption somewhere between these extreme limits appears to be the only way of explaining the fluctuations. It will be seen at once that, while local oscillations may be present, they cannot be invoked to account for the main phenomenon.

If oscillations of the whole crust take place, a natural procedure is to search for evidence of them in terrestrial phenomena. With a crust formed of uniform and unbroken material like that which composes the surface, detection would be difficult, because the resulting strains and pressures are far within the elastic limits. From the actual crust, of unequal heights, fissured in all directions and undergoing constant change from erosion, something observable may be expected. Adjustments, especially those needed for isostatic compensation, are continually taking place, and might be expected to be more frequent with or soon after a change of radius. The interpretation given here requires the earth's radius to be below its mean value from about 1790 to 1898, and a change near this latter date from the minimum to the maximum value taking taking place within a very few years, as well as a further sudden change to the mean value about 1917. Other sudden changes may have occurred in the past, but the observations lack the accuracy needed for definite statements.

Some attempts to correlate the observations with seismic phenomena have been made. Prof. H. H. Turner some years ago deduced a period of between 200 and 300 years from the records of Chinese earthquakes, and suggested that it might be related to the lunar deviations. In this connexion it must be remembered that the curve of Fig. 1 represents nearly all our present knowledge; we do not know the extent to which the period or amplitude as deduced from this curve may represent what has taken place in earlier centuries. I have attempted a comparison with the frequency of British earthquakes from the material collected by Davison in his "History of British Earthquakes." There are indications of some correlation, but as they depend partly on the curvatures at different places of the curve in Fig. 1, there is doubt as to their reality. Correlation with the intensity of volcanic action was also briefly examined without success. The records of Kilauea as gathered by Dana and others would probably have served as a test if the material had been as complete and continuous as that gathered by Dr. Jaggar since 1911.

One remarkable correlation seems to be well founded, namely, the close correspondence between the frequency of British earthquakes on one hand and the difference between the Greenwich observations and the occultations on the other. Since the occultations are gathered from observations in widely different places and are nearly free from systematic error, it would seem that the Greenwich observations are subject to a small systematic error which depends on local earth-movements. This same difference is also correlated with the lunar deviations. Closer examination of these correlations has not furnished any explanation for their occurrence.

The applications of the hypothesis, assuming that the oscillations have existed for long periods, to the formation of the surface features of the globe are far-reaching. Their source must obviously be sought in the physical and chemical conditions of the earth below the outer crust. It follows that a large supply of energy is available for external use. Adjustments to relieve the strains indirectly caused by erosion will be more frequent than without the oscillations; and the accumulated strains will be smaller. General statements of this character, however, do little more than furnish a basis for detailed investigations of specific problems. Can such oscillations, for example, constitute a factor of importance in the building of a mountain chain bordering a deep depression, as in the Pacific area? Will there be vertical or horizontal differential movements of continental areas, and, if so, can such movements be detected in variations of sea-level or of deposition of sediments? As to the latter, an inch of deposit in 200 years is 400 feet in 1,000,000 years, or 80,000 feet in 200,000,000 years, so that the magnitudes involved are of the right order for observation if the phenomenon exists. Many other questions of a similar character will occur to the geologist and the geophysicist.

The Principles of Biological Control in Economic Entomology.[1]

By Dr. R. J. TILLYARD, F.R.S., Chief of the Biological Department, Cawthron Institute, Nelson, N.Z.

I.

THE CONTROL OF INJURIOUS INSECTS.

IN considering the possibilities of success of the method of biological control of injurious insects, we have to take into account a number of factors, the most important of which are the climatic conditions and the amount of economic disturbance in the affected area. The most striking successes in control have been made in countries with a warm and equable climate, in which new beneficial insects can be introduced with greater ease and, when introduced, flourish and spread more rapidly, than in countries in which either a marked change of seasons or a severe winter has to be faced. But this climatic factor, important as it is, must rank only second to another factor, which may be termed the *amount of disturbance* of the affected area. To illustrate this point, let me take the case of an apple orchard in Australia or New Zealand. Ecologically speaking, one is no more a part of Australia than the other is of New Zealand; both are little pieces of Old England translated to a new environment with the same plant, the apple-tree, attacked in the same manner by the same pests, codlin-moth, woolly aphis, and the rest (fortunately by no means all of them are present either in Australia or New Zealand), and the same problems of cultivation, spraying, picking, and marketing. The same is true of a dairy farm or a planted forest area of exotic pines. In all these cases, before man came on the scene, the same piece of soil presented an entirely different ecological problem, with only native plants and native animals in the picture. Thus these apple orchards, these dairy farms and forest plantations, are pieces of *disturbed country*, and the amount of disturbance might, perhaps, be mathematically expressed by a formula which would show the percentages of original plants and animals remaining on the area.

---

[1] From the Trueman Wood Lecture of the Royal Society of Arts, delivered on Oct. 27, 1926.

Now the crux of the whole problem, of course, is the difference between the ecological interplay of various factors in their natural habitat and in the disturbed country. Take, for example, the case of an apple orchard in New Zealand, attacked, let us say, by the woolly aphis, *Schizoneura lanigera*. The original home of this pest was North America; in many countries it is still called 'American blight.' The pest, when studied a few years ago in New Zealand, was found to be almost unbelievably virulent, and was really threatening the continuance of the apple industry. In America, on the other hand, it has never attained anything like the same degree of severity. The more favourable climate of New Zealand is evidently one of the factors making for increased severity of the pest; but the main cause of it is clearly to be seen as arising from the incomplete balance of Nature in a piece of thoroughly disturbed country. In other words, man, after destroying the original association of plants and animals on the area, had proceeded to introduce (1) the apple tree, and (2) (unwittingly of course) the woolly aphis, without balancing this association by (3) the natural enemies of the woolly aphis in the form of parasitic and predatory insect enemies.

Let us now note carefully the effect of the scientific attempt to redress this lack of balance. The task was given to me six years ago, as the most pressing problem of the moment, when I joined the staff of the newly formed Cawthron Institute in Nelson. In the course of a visit to America, undertaken with this as one of its main objects, I found that there were three kinds of insects which attacked woolly aphis successfully enough to make them worthy of consideration. These were (1) syrphid flies of the genus Pipiza, (2) the Californian ladybird beetle *Hippodamia convergens*, and (3) the chalcidoid wasp *Aphelinus mali*. In considering which of these to introduce into New Zealand, I rejected the syrphid flies because of the abundance of allied native forms in New Zealand and their inability to make headway owing to severe parasitism from Ichneumonidæ. As regards the other two insects, all the evidence seemed to point in favour of *Hippodamia convergens*. It had a wonderful record in California and was rightly regarded as one of the most valuable of known beneficial insects. Large sums of money have been spent in rearing, collecting and distributing it, and every Californian fruit-grower is fully convinced of the benefits which it confers upon him. Opinions regarding *Aphelinus mali*, on the other hand, were not so uniformly favourable. It had already been introduced into South Africa, where it was considered to be a failure. If I had had to make a choice, the evidence would have been in favour of Hippodamia. However, I was able, through the great kindness of Dr. L. O. Howard, chief of the Bureau of Entomology at Washington, D.C., to obtain good supplies of both these insects. The results were very interesting. *Hippodamia convergens* was introduced and liberated in thousands throughout the Nelson Province, but has not since been seen or heard of. It is probable that its known habit of seeking the tops of high mountains and hibernating beneath the snow has proved its undoing, for it has failed to establish itself permanently in every country into which it has been introduced. *Aphelinus mali*, on the other hand, after being kept alive with great difficulty during the first winter in New Zealand (the period corresponding with the *summer season* in North America which it should normally have experienced), became acclimatised and increased with great rapidity and vigour in the insectaries. In the course of three or four years it was distributed in large numbers to all commercial apple orchard centres in New Zealand. The result has been that woolly aphis is now under satisfactory control in New Zealand and is no longer regarded as a serious pest. The New Zealand strain of this insect has also been sent over to various parts of Australia and is proving highly beneficial there.

As regards Australia, the conditions there are very different from those in New Zealand, but I do not wish it to be thought that biological control has no future in that great country. California is part of a great continent almost as big as Australia; yet good results have been obtained there by the method of biological control. The reason is, perhaps, that California itself is really an ecological 'island,' separated from the rest of the continent by barriers of mountain and desert. If that be so, then there is great hope of successes in Australia. First of all, the whole country is an island, both geographically and ecologically, as well as a continent. Secondly, it is made up of a large number of diverse areas separated from each other, as California is from the rest of North America, by mountain barriers or great stretches of desert. Looked at from this point of view, Western Australia, for example, should provide almost as perfect a field for biological control as New Zealand, while many parts of eastern Australia, such as the elevated apple lands of South Queensland, should be ideal for application of the same methods.

I now wish to emphasise the advantages which the biological method of control has over the chemical method. First of all, control of an insect pest by spraying or fumigation is only *annual* control, not *permanent* control, and it only extends to those areas in which it is faithfully carried out. Let there be any slackening, either in place or time, of the strict spraying schedule, and the insect pests immediately take advantage of it. Further, the cost of chemical control is a continuous annual drain on the industry, whereas the cost of biological control is a definite amount, terminating when the beneficial insect has been successfully established.

I think it would be of interest to give a short account of the principal researches in biological control of insect pests which are at present being carried out in Australia, New Zealand, and Fiji.

1. *Control of Woolly Aphis.*—The New Zealand strain of *Aphelinus mali* has been sent across to all six Australian states, and is now being reared and distributed over there. Reports indicate that success is being steadily attained in Queensland and Western Australia, while in the other States the work is not sufficiently advanced to say what the result will be.

2. *Control of Pear Leaf-Curling Midge* (*Perrisia pyri*).—Mr. David Miller, Government Entomologist of New Zealand, is now engaged on the problem of introducing beneficial parasites on this bad pest. Supplies of *P. pyri* are being forwarded by the Imperial Bureau of Entomology in London, and attempts are being made to establish species of Inostemma and Platygaster known to be present. Judging by latest reports, considerable progress is being made with the species of Platygaster, and a favourable result to this important investigation may reasonably be looked for.

3. *Control of Earwig* (*Forficula auricularia*).—This insect is a very serious pest of peach and apricot orchards in the irrigation areas of Teviot and Central Otago, New Zealand. An attempt was made to introduce the parasitic tachinid flies, *Digonochæta setipennis* and *Racodineura antiqua*, through co-operation between the Imperial Bureau of Entomology, Rothamsted Experimental Station, and the Cawthron Institute, Nelson. Considerable progress was made, but the work came to an untimely end through the long illness of Mr. H. M Altson, who had charge of the work in England. The work is now again to be taken up, and the experience gained in the previous attempt should be of great value in this very difficult problem. One great advantage which New Zealand possesses over America in this case is the absence of the secondary parasites of the tachinids. The most abundant of these, *Dibrachys boucheanus*, is already present at Portland, Oregon, where the earwig infestation is worst, and renders the problem almost hopeless so far as control by tachinid parasites goes.

Parenthetically, a curious illustration of the unforseen difficulties which arise in this highly specialised work may be here mentioned. The waxmoth, *Galleria mellonella*, is becoming a serious pest in New Zealand, and a request has been made that the Cawthron Institute should endeavour to introduce a natural enemy to check it. Now it so happens that the only parasite which appears to be at all promising is *Dibrachys clisiocampæ*, which is so closely allied to *Dibrachys boucheanus* that it must be kept out of New Zealand at all costs if the experiments in controlling earwigs are ever to succeed. Consequently either the fruitgrowers or the bee-keepers must be disappointed. I have no hesitation in deciding that the earwig is by far the worse pest of the two insects in question ; and so, if the waxmoth is to be controlled by its natural enemies, some species which will not attack the tachinid parasites of the earwig must be used instead of Dibrachys.

4. *Control of Oak Scale* (*Asterolecanium variolosum*).—This insect, never a serious pest in Europe, has become so abundant on British oaks in parts of New Zealand that it is actually killing them. The only known parasite is *Habrolepis dalmanni*, of which several consignments have been received at the Cawthron Institute from Dr. Howard. A large number of females were reared from the last consignment, and, if it turns out that this species is parthenogenetic, there will be a very good chance of establishing it and so checking the scale.

5. *Control of Introduced Aphids in General.*—Only one or two very rare native species of aphids are known in New Zealand, but there are a considerable number of injurious introduced species. One of the most curious gaps in the New Zealand insect fauna is the complete absence of the green lacewings or Chrysopidæ, which are such a valuable check on aphids in other parts of the world. An attempt is therefore being made by the Cawthron Institute to acclimatise these insects in New Zealand. A fine consignment of 1900 hibernating adults of an undetermined Canadian species has been received in excellent condition, through the kind offices of Mr. Gibson, the Dominion Entomologist of Canada, and Mr. Downes, the State Entomologist of British Columbia. Three generations have already been reared and a fair number have managed to survive the rather too warm winter of Nelson. There seems to be a reasonable prospect of the final establishment of this or some other similar species throughout New Zealand.

6. *Control of Pear Slug* (*larva of Eriocampoides limacina*).—This pest is bad on pear, quince, plum, cherry, and hawthorn throughout New Zealand and Tasmania, and in parts of Australia. An attempt was made to introduce from England the ichneumon parasites of the genus Perilissus. Consignments were sent to the Cawthron Institute from Rothamsted Experimental Station. Nearly two years elapsed before the insects hatched out. They were then carefully paired in special cages and liberated into an insectary containing plenty of pear slug, which they attacked with vigour. It seemed almost certain at that point that success would be attained. But, alas ! one of the unknown bionomic factors intervened, for the entire succeeding brood proved to be males, and so the race died

out. This extraordinary example of the difficulties attending this kind of research may fittingly be used as an extra argument in favour of giving the strongest encouragement to those engaged in pure entomological research. Until we know for certain the factors governing the production of single sex broods in Hymenoptera, and also far more about parthenogenesis in this order than we do at present, we may not be able to succeed with the introduction of many valuable parasitic insects into Australia and New Zealand.

7. *Control of Sheep-Maggot Flies.*—This immense problem, of the utmost importance to Australia and other sheep-raising countries, need not be dealt with at all fully here, because up to the present no satisfactory method of biological control has been discovered. Much work has been done with several well-known chalcidoid parasites of the blow-fly larvæ and pupæ, but in no case has the percentage of parasitism produced been high enough to warrant the continuance of the work. At the present time, the interesting parasitic hymenopteron *Alysia manducator* is being collected in England by Dr. J. G. Meyers for shipment to Australia, and it will be interesting to watch the progress of the attempt to acclimatise and spread this very active insect in a warmer climate and new conditions of life.

8. *Control of Coco-Nut Moth* (*Levuana irridescens*).—This very serious pest, the original home of which is still unknown, is a small zygænid moth the larva of which feeds along the midrib of the leaflets of the coco-nut palm. In the island of Viti Levu, Fiji, it increased enormously during the past ten or twenty years, until its depredations had so weakened the trees and reduced the yield of copra that the very foundations of the industry were tottering. During the past few years scientific workers have been engaged on the problem of discovering and introducing the natural enemies of species closely allied to *Levuana iridescens* from Malaya. A parasitic tachinid, *Ptychomyia remota*, has been introduced and successfully established with very promising results, and it would appear that this formidable problem is now in process of solution.

(*To be continued.*)

Whither?—a Footnote.

"*What, then, is Life? Is it . . . a . . . possibly quite unimportant by-product of natural processes, which have some other and more stupendous end in view? . . . Or, throwing humility aside, is it the only reality, . . . ?*"—J. H. Jeans, Nature, Dec. 4, 1926.

Ribbed, breathing flesh thrice often crucified!
Veined vase of Life! lo, whether for bliss or curse
A wondrous thing the wheeling universe,
Engendering thee, lifts shapen from scarred Earth's side!
Reared in primeval war of rock and tide,
Thence hither—by what wayfaring perverse!
Thy fashioning? runs it ended more than theirs,
The stars in flow that sphere from vapours wide?
How camest thou by that strange gift ungiven
To aught else earthly, the old fruit forbidden,
To know thyself, as part to glimpse a whole,
And, that within thee, clasping earth and heaven
For comrades of like faring, to—storm-ridden—
Confront, brow raised, the incognisable goal?

C. S. S.

Obituary.

Prof. A. de Quervain.

The death of Prof. A. de Quervain at the comparatively early age of forty-seven years, which occurred at Zurich on Jan. 13, is a serious loss to European meteorology. His fellow-members on the different international commissions to which he belonged will miss a colleague who had endeared himself to them by his earnest enthusiasm and by his lovable disposition.

de Quervain was born on June 15, 1879, in the Canton of Berne. After studying at Neuchâtel and Berne he went to Paris as assistant, from 1898–1902, in the Observatory at Trappes, where the late Teisserenc de Bort was developing the exploration of the upper atmosphere by means of *ballons-sondes*. This led, in 1899, to the discovery of the stratosphere. In 1901, Teisserenc de Bort made arrangements for observations with *ballons-sondes* in Russia. Prof. de Quervain was placed in charge of the work and obtained observations of temperature in the upper air both at St. Petersburg and Moscow up to heights of 10 kilometres. After leaving Trappes, de Quervain went to Strasbourg, where the results of the international investigation of the upper air were collected and published under the direction of Prof. Hergesell. de Quervain acted as secretary to the international commission, and became impressed with the advantages which would accrue if the balloons which were used for carrying the recording instruments could also be observed during their ascent, so as to give information about the upper wind. Physical difficulties in the way of making these observations for an hour or more with an ordinary theodolite had formed a practically insuperable obstacle. de Quervain overcame this difficulty by inventing, in 1905, the theodolite with the reflecting prism, which is now practically universally adopted for observations with pilot balloons: no invention has contributed more than this to our knowledge of upper wind. It was exceptionally fortunate for meteorology that de Quervain came, during these eight years, under the influence of two such pioneers in the investigation of the upper air as Teisserenc de Bort and Hergesell. They were both inspired with the conviction that the exploration must be world-wide, and themselves carried out investigations in different parts of the oceans.

Prof. de Quervain returned from Strasbourg to Zurich, where he continued his investigations of the upper air, publishing in 1908 a thoughtful contribution on cloud studies and some notes on the connexion between clouds and the actual conditions of temperature in the upper air. In 1909 he was the leader of a joint German-Swiss expedition to Greenland, and the experience which he then gained enabled him, three years later, to lead a Swiss expedition successfully across Greenland from west to east. This was the first time the interior of the country had been traversed. (A short crossing nearer the southern extremity had been made in 1888 by Nansen.) The highest point reached was 2510 metres (about 8200 feet), 260 miles from the west coast and 150 from the east coast. The scientific results of the expedition, prepared jointly by de Quervain and his companion Mercanton, were published in 1920, and constitute the observational basis of our knowledge of the meteorology of the interior of Greenland.

When the international meteorological organisation resumed its work after the War, de Quervain became a member of the Commission for Weather Telegraphy. He had a profound knowledge of the observational side of meteorology, which proved most valuable in the difficult work of extending the international exchange of observations to meet post-War conditions. He spoke frankly when he saw the risk of a wrong decision being taken, but in a way which not only convinced his colleagues, but also endeared the speaker to them.

One project dear to de Quervain's heart was the establishment of an observatory on the Jungfraujoch at a height of 3500 metres, and for this he gained the warm support of the Commission. After the recent meeting last September at Zurich, many members of the Commission went to see the observatory, but to his great regret de Quervain was too ill to lead them. Owing to his unique knowledge of clouds he was chosen to be chairman of the subcommission appointed in 1923 at the conference at Utrecht to consider the revision of the method of reporting observations of cloud and weather in the international code. Before this task could be completed he was unfortunately seized, in 1924, by an illness from which he never completely recovered. He was, however, able to be present for a short time at one of the meetings at Zurich in September 1926, when the Commission gave its approval to a new trial code based on his work and showed its warm appreciation of his services and its sympathy with him in his illness.

de Quervain's death, when it came, was quite unexpected. He is survived by his wife and four children. It is fitting to record that Mme. de Quervain, imbued with a like enthusiasm for exploration, and resolute in face of the danger and hardship, went to Angmagsalik on the east coast of Greenland in 1912 to meet her husband after his perilous journey and to accompany him on his return to Europe.

E. G.

M. M. DELAFOSSE.

WE regret to record the death, on Nov. 13, in his fifty-sixth year, of M. Maurice Delafosse, the distinguished ethnologist and authority on African languages. Maurice Delafosse was born at Sancergues (Cher) on Dec. 20, 1870. On completing the usual educational course, he became a student at the École des Langues Orientales Vivantes, where he obtained his diploma in 1894. In the following year he was appointed to the French Government service in West Africa. This was the beginning of a distinguished official career, during which he held a number of important appointments: Consul in Liberia, 1897; member of the Anglo-French Boundary Commission on the Ivory Coast-Sudan-Gold Coast Frontiers, 1903; administrative officer of the Ivory Coast; political officer of the Government at Dakur, 1915; Governor of Oubangui-Chari, 1918.

In 1918, Delafosse retired and thenceforth devoted himself to the linguistic and ethnographical studies to which he had given considerable attention throughout his official career. He became professor of native customs and languages at the École Coloniale, and of Soudanese languages at the École des Langues Orientales Vivantes. He was also appointed Membre du Conseil Supérieur des Colonies and Membre Effectif of the International Colonial Institute at Brussels, Member of the Commission de l'Esclavage at Geneva, and Director of the Institut International pour l'Étude des Langues et Civilisations Africaines. He was one of the founders of the Institut d'Ethnologie.

Delafosse was a frequent contributor to *L'Anthropologie*, *La Revue d'Ethnographie*, and other specialist periodicals, and was the author of a number of books dealing with African languages and peoples. Among these were manuals of Dahomian, Agni, Haussa, Mende, and a comparative vocabulary of more than sixty languages or dialects spoken on the Ivory Coast. His ethnographical work included studies of the Sara (Chad) and the peoples of Liberia and the frontiers of the Ivory Coast, Sudan, and Gold Coast, the Senufi, and the peoples of the Upper Niger. Of a more general character were his "Les Noirs de l'Afrique" and "Les Civilisations Négro-Africaines." He was greatly interested in the recently formed International Institute of African Cultures and Languages, of which he became joint director. His death at a comparatively early age, which was largely due to ill-health contracted during his residence in Africa, is a great loss to ethnographic and linguistic studies, not in France alone, but wherever primitive, and especially African, races are a subject of serious study.

WE regret to announce the following deaths:

Sir Digby Pigott, Controller of H.M. Stationery Office from 1877 until 1905, an authority on the birds of London, aged eighty-six years.

Prof. E. H. Rennie, professor of chemistry in the University of Adelaide, known for his work on the chemistry of Australian plant products, aged seventy-four years.

Dr. Walter Seton, secretary of University College, London, and also secretary to the Ramsay Memorial Fellowship Fund established in memory of the late Sir William Ramsay, on Jan. 26, aged forty-four years.

News and Views.

In his article elsewhere in this issue (p. 200), Prof. E. W. Brown makes out a strong case for the belief that the chief outstanding anomalies in the motions of the moon, the sun, and the inner planets are due to errors in time-keeping arising from variations in the earth's rate of rotation. A set of the most puzzling departures of astronomical observation from gravitational theory has therefore been brought into harmony. The ratio of the chief inequalities in the longitudes of the sun and moon is such as to indicate that the variations of the rate of rotation are not associated with any corresponding transfer of angular momentum to the moon's orbital motion, and therefore Prof. Brown attributes them to changes in the earth's moment of inertia. Symmetrical swellings and contractions of the earth would certainly give rise to effects of the type observed. But elastic vibrations of the earth of this type would have periods of the order of minutes, not years, and it is difficult to think of any geological or seismological process that could give simultaneous expansion or contraction over the whole earth. An alternative explanation resting on a phenomenon already known to occur may be found in variations of the thickness of the polar ice-caps. Partial melting of the polar ice and redistribution of the water over the ocean would give changes of the moment of inertia such as are required, and the amount does not seem prohibitive. A small secular increase in the amount of ice would also give a secular acceleration of the earth's rotation, which would go some way towards explaining the outstanding discrepancy between theory and observation with respect to the ratio of the secular accelerations of the sun and moon. There is evidence of a warm climate in Europe about 2000 B.C., which would fit this suggestion.

A committee consisting of representatives of the Royal Society, the Royal Colleges of Physicians and Surgeons, the Royal Society of Medicine, the British Medical Association, the universities, and other institutions interested, has been formed to organise a celebration in London of the centenary of the birth of Lord Lister, which falls on April 5 next. Representatives of learned societies, universities, and medical bodies in Great Britain, and delegates from the Dominions and principal foreign countries, will be present. The delegates will be received by H.M. the King at Buckingham Palace on Monday, April 4. The programme so far arranged is as follows: April 5.—Reception and short addresses by some of the delegates in the large hall of the British Medical Association; conversazione at the Royal College of Surgeons of England: dinner given by the Merchant Taylors' Company, of which Lister was a member. Apr. 6.—Memorial service in Westminster Abbey, and an address by the Bishop of Birmingham; discourses in the Robert Barnes Hall of the Royal Society of Medicine on "Lister as Physiologist, Pathologist, and Surgeon," by Sir Charles Sherrington, Prof. W. Bulloch, and Sir Berkeley Moynihan; and a conversazione at the rooms of the Royal Society.

Few individual acts can have had more unforeseen consequences than when Gordon Bennett sent Stanley to find Livingstone. That was in 1869. In 1875 Stanley set out on his second expedition into Africa, financed by the *New York Herald* and the *Daily Telegraph*. That same year Stanley wrote from Uganda: "Nowhere is there in all the pagan world a more promising field for a mission than Uganda." The challenge thus thrown down was taken up by the Church Missionary Society, which has just been celebrating the jubilee of the Uganda Mission. To-day the church in Uganda has a membership of 165,000 baptized Christians, while one of the important industries of the country, namely, cotton growing, was due to a missionary. At the celebration, in which the Archbishop of Canterbury, Lord Burnham, and other distinguished men took part, it was announced that a tablet to the memory of Stanley is to be erected in St. Bride's Church, Fleet Street, one of the inscriptions to read: "To the Glory of God. In memory of Sir Henry Morton Stanley, Bula Matari (Rock Breaker), Explorer, Author, Newspaper Correspondent. 1841–1904. Challenged the Christian Church to Evangelise Uganda. 'Here is your opportunity: embrace it.'"

On Feb. 8 occurs the bicentenary of the birth of Jean André De Luc, F.R.S., the Swiss physicist and geologist who for more than forty years was reader to Queen Charlotte, consort of George III. Born in Geneva in 1727, he was well educated and took up a business career. Having a taste for study, however, he worked at meteorology and geology and made excursions among the Alps. In 1773 he came to England, and it was apparently the publication of his "Recherches sur l'Atmosphere," published the previous year, which gained him admittance to scientific circles. He afterwards made tours on the Continent, but England was his permanent home, and he died at Windsor in 1817. In physics, De Luc is credited, among other things, with noting that when a mixture of ice and water is melted the temperature remains constant until all the ice is melted. It was for his writings on geology he was principally known, and though these, to-day, are only consulted by the curious who, as Geikie said, have "leisure and inclination to dig among the cemeteries of geological literature," De Luc's devotion to science was lifelong and sincere. His "Lettres Physiques" of 1778 contains one of the earliest examples of the use of the word 'geology' in its modern sense. He is frequently mentioned in the memoirs of the time, such as Madame D'Arblay's; it is to him Watt speaks his mind about the water controversy, while Queen Charlotte refers to him as the "good old De Luc."

In an article on electrification and the Electricity Act in the *Quarterly Review* for January, Sir Charles Bright makes a strong plea for electrical progress. He points out that industrial success is largely based on the possession of an abundant supply of cheap and efficient power. He thinks that too much stress is often laid on having great hydro-electric resources. Although America's potential resources in water power are enormous, the bulk of its electricity is produced by coal. The compact nature of the load in England makes it an ideal country for the development of electrical power. In Germany, brown coal production is rapidly outstripping the production of black coal. There seems no reason why peat, of which he declares we have a superabundance, should not be similarly employed by us. If conservatism and a narrow care for established interests should hamper the future wide electrification of Great Britain, the generations to come are sure to suffer from our shortsightedness. The Electricity Act gives us a great opportunity of increasing our industrial efficiency. The technical work will be in the hands of the Electricity Commissioners. The Central Electricity Board, of which Sir Andrew Duncan is the chairman, will be concerned merely with administration; its functions will be very similar to that of a board of directors. It seems certain that the successful working of the scheme will add to the national well-being, and useful constructive criticism will help greatly towards this end.

A LARGE and representative meeting of British botanists was held at the Linnean Society's rooms on Thursday, Jan. 27, to initiate arrangements for the fifth International Botanical Congress, which is to be held in England in 1930. Dr. A. B. Rendle, who presided, announced the acceptance of the invitation extended to the botanists meeting at Ithaca last August on the occasion of the fourth Congress, to meet in Great Britain in 1930. The meeting having constituted itself a general committee, it was decided that the coming Congress should deal with pure botany only, applied sciences such as agronomy, forestry, horticulture, and pharmacognosy being excluded. An executive committee was appointed as follows: Sir David Prain, Prof. A. C. Seward, Prof. A. G. Tansley, Prof. V. H. Blackman, Prof. W. Neilson Jones, Prof. Walter Stiles, Prof. Dame Helen Gwynne-Vaughan, Dr. A. W. Hill, Dr. A. B. Rendle, and Mr. F. T. Brooks. The committee was empowered to add to its number as might be found advisable.

AN earthquake, that must have been of great strength near its origin, was felt in the eastern and north-eastern counties of Scotland at about 5.20 A.M. on Jan. 24. The disturbed area includes the Orkneys, the counties of Caithness, Nairn, Elgin, Banff, Aberdeen, Kincardine, Forfar and Fife, and at least the eastern half of Perthshire. The boundary, so far as it can be traced from the early reports, is a nearly north-and-south line concave towards the east, and therefore pointing to an origin outside the country and either in the south of Norway or just west of the Norwegian coast. At the same hour it appears that an earthquake was felt over a large part of southern Norway, and there can be little doubt that this shock was connected with the tremors felt in Great Britain. As the shock reached an intensity of 6 (Rossi-Forel scale) at Banff and Aberdeen, and 5 at Kirkwall and at Ladybank in Fifeshire, it is probabl that later reports will show that the earthquake wa felt over the greater part of Scotland and possibl in the extreme north of England. It was recorde by seismographs in the observatories of Edinburg and Kew. In Morayshire and Nairnshire an earlie shock was felt at 11.5 P.M. on Jan. 23. It is wort recalling that on previous occasions—for example, o Mar. 9, 1866, and Jan. 4, 1879—Norwegian eart quakes were felt in Great Britain, but never befor so far as known, over so wide an area.

AT a meeting of the Newcomen Society, held a the Science Museum on Jan. 26, Mr. A. Titley read paper on Trevithick and Rastrick, and the singl acting expansive engine. About a year ago an ol note-book, dated 1813, belonging to Rastrick, cam to light. This contained sketches, dimensions, an calculations regarding a 6-H.P. engine, but a grea many dimensions were given in cipher. Mr. Title found the clue to the cipher, and from the note-boo was able to make working drawings. The engine however, proved to be very like the Trevithick engin preserved in the Science Museum, South Kensingtor which was built under the patent of 1802 of Trevithic and Vivian, and is evidence of the close co-operatio of Trevithick and Rastrick. At the same meetin Mr. Jenkins was able to announce that during search by Mr. Watkin of the archives of Dartmout deeds bearing the signature of Thomas Newcomen ha been discovered. These are the only specimens, i England, of the inventor's handwriting, and they g far to establish the authenticity of a letter of New comen's preserved in Berlin.

PROF. A. S. EDDINGTON, in his second Giffor Lecture in the University of Edinburgh on Friday Jan. 28, considered certain problems of time and spac He said that two distinct questions arise: first, wha is the true nature of time? and secondly, what is th nature of that quantity which has, under the name c 'time,' become one of the main foundations of th whole scheme of experimental and theoretical science As physicists we are interested in the latter quantity and this turns out to be relative and is mixed up wit space. Einstein's theory, having cleared up thi point, was able to approach the first question, an was able to rediscover—not in the three-dimensiona but in the four-dimensional world—the time which w feel is essentially distinct from space. This is calle 'interval,' because the vested interests have otherwis appropriated the name 'time.' We have every righ to object in the name of common sense to a confusio of two things so obviously distinct as space and tim but that means we must abandon the partiall unsuccessful attempt made in classical physics t divide them, and go into the four-dimensional worl where we can make a more satisfactory separation o them.

VIEWING the world, said Prof. Eddington, we se distant events happening 'now,' and this has led u to conceive an instant 'now' not confined to 'here but spread through all space, so that we regard th enduring world as stratified—composed of a succession of world-wide instants. This conception ought to have died in 1667, when it was discovered that light takes time to travel; it is not the event but the seeing of the event which is 'now.' The idea of world-wide instants is firmly rooted, however, and the scheme has to be patched up by placing these distant events in some past instant. But the construction of the world-wide 'now' became a matter of artificial calculation, and it turned out that the resulting construction was different for observers with different notions, so that 'now' relative to one was not 'now' relative to another. The absolute structure of the enduring world contains nothing corresponding to world-wide instants; it is not stratified. The physical nature of the world is seen more clearly and simply when this stratification, arbitrarily imposed, is removed—it appears simpler though less familiar.

The third assembly of the International Federation of Intellectual Unions met at Vienna on Oct. 18, 19, and 20, 1926. A report which has reached us in multiplex typescript includes a cordial invitation to more active participation by British intellectuals. The Federation originated as a post-War French-Austrian *rapprochement*. The Vienna assembly has endorsed, and carried forward, the resolutions of an earlier assembly at Milan. Some preliminary contacts have already been made with the P.E.N. Club, the English League of Nations Union, the Carnegie Foundation, the Institut International Intermédiaire in Holland, the Institute of International Education in New York, and the Intellectual Relations Committee of the Société des Nations. Other countries are forming 'intellectual unions,' and those who seek the co-operation of Great Britain are a little baffled by the absence of any general British Intellectual Union, and inquire as to the possibility of starting one. Communications would also be welcomed from North America, Latin America, Americans travelling in Europe, and Soviet Russia.

The secretary of the International Federation of Intellectual Unions is Prince Charles de Rohan, Schloss Albrechtsburg, Post Loosdorf, bei Melk, Lower Austria. The most general object of the Federation is the supra-national organisation of Europe on an intellectual rather than on a political basis. It is assumed that the success of the more general conversations on peace, reconciliation, and fellowship now justifies the organisation of co-operative work. The programme includes the promotion of lectures in other countries by representative exponents of their own national cultures (thus, Rabindhranath Tagore has lectured in Italy), the discussion of some of the general problems of the evolution of civilisation, the arrangement of 'passeports intellectuels' or personal introductions for savants travelling abroad, and the planning of family hospitality for younger students. There is a proposal for a European press agency exchanging magazine articles and promoting the translation of new and significant works into various languages. Already on an independent business footing there is *L'Europäische Revue*, published in Leipzig. For some words like 'nation' and 'democracy,' which have different implications in French and German leading to continual misunderstandings, it is proposed to prepare a special dictionary.

The Federation complies with one of the conditions of permanence in public international organisations; it offers an open door and a warm welcome, but should be on its guard against not impossible risks of intellectual snobbishness. It is already difficult enough to try to interest socialists in international scientific societies, which are felt to be bourgeois. It is not so clear whether the Federation satisfies a second condition, that of definite purposes clearly laid down in articles of association. At the moment there is an impressive imprecision. But whatever form the political organisation of Europe may take, there is a place for thinking organisations exploring the way to the future far in advance of what statesmen call practical politics.

In his presidential address to the Indian Science Congress which met recently at Lahore, Sir J. C. Bose briefly summarised the results of his many years of research on the physiology of movement and irritability in plants. He dwelt upon the important conclusion that the physiological mechanism of the plant is essentially similar to that of the animal: in both there are contractile, rhythmic, and nervous tissues. In particular he expressed his conviction that the 'automatic' or 'spontaneous' movements of plants are to be attributed not to 'internal stimuli' but to the accumulated energy of stimuli acting from without. He concluded by pointing out how, by the gradual evolution of will, it has become possible for man to control the action of, and his response to, external stimulation, so that he is now no longer merely a passive subject of his environment.

A committee has recently been formed in Paris to raise funds for the erection of a monument to the memory of the famous French engineer, Gustave Alexandre Eiffel, the builder of the Eiffel Tower. Born in Dijon on Dec. 15, 1832, Eiffel was trained as a civil engineer at the École Centrale des Arts et Métiers in Paris and became known as a great bridge builder. The contract for the tower which formed such a feature of the International Exposition of 1889 was signed in Jan. 1887, and the full height was reached on Mar. 13, 1889. The steel lattice work reaches a height of 984 feet, 580 higher than St. Paul's Cathedral in London. It has served many purposes, and during the War proved invaluable as an anti-aircraft station, while General Ferrie, the Inspector of Military Telegraphs, said that as a radio station the tower served so many purposes that if it had not existed it would have been necessary to build it. Eiffel died on Dec. 28, 1923, at the age of ninety-one years.

In a pamphlet entitled "The Present Status of the Wild-Fowl of Europe," Dr. P. R. Lowe, of the British

Museum (Natural History), presents the case for further legislation for the increased protection of wild-duck (including swans and geese) and waders (plover, snipe, curlew, woodcock, sandpiper, etc.) in Great Britain and Ireland. Exploitation of these birds for commercial and other purposes in Europe has increased to such an extent that the rate of destruction exceeds the rate of reproduction. The position has become so serious as to cause the Swedish Government to move in the matter and to suggest international regulations for the more effectual protection of wild-fowl on migration. A committee was appointed at the International Ornithological Congress held at Copenhagen last May to consider the proposals of the Swedish Government, and a resolution was submitted to the General Congress, and passed, supporting the proposal for an international conference and asking delegates to prepare reports dealing with the facts as they affected their own countries. These reports will be considered at the International Congress which it is hoped to hold before the end of the present year. Dr. Lowe's report represents the British case, and deserves the careful consideration of ornithologists. While it appears from Dr. Lowe's detailed analysis that the situation in Great Britain is less serious than in other European countries, it is made abundantly clear that international co-operation is called for if European ducks and waders are to be saved from a steadily approaching doom.

In order to mark the end of the fiftieth year of publication the *Chemiker-Zeitung* has published a special jubilee number (Dec. 29). The issue contains many messages of appreciation from eminent technologists and from distinguished foreigners. Amongst the latter we note the names of Profs. E. Cohen of Utrecht, Mme. Curie of Paris, G. Georgevics and J. Stoklasa of Prague, A. E. Holleman of Amsterdam, W. A. Noyes of Illinois, F. Ullmann of Geneva, and R. Wegscheider of Vienna. Articles of special interest are contributed by many well-known authorities. Prof. Ostwald writes on the future of chemistry in Germany, Prof. Oppenheimer of Berlin on enzyme oxidations, Prof. E. Laqueur of Amsterdam on the three hormones, thyroxin, insulin, and menformone, Dr. A. Weinberg and Prof. F. Mayer on different aspects of the dyestuff industry, Dr. Bergius on the utilisation of coal, etc. Several contributions by prominent authorities, including one by Prof. H. E. Armstrong, are to follow shortly.

The *Chemiker-Zeitung*, which is well known not only throughout Germany but also in other countries, has rendered important service to the rapid development of industrial chemistry, both by reason of its valuable survey of scientific and technological progress and by the wide publicity of its advertising columns. Founded in 1876 by the bold enterprise of Dr. G. Krause in his native town of Cothen, it rapidly achieved success. The first four-page 'specimen-number' was published on Dec. 4, 1876; on Jan. 5 in the following year the first part of Volume 1 duly appeared, and before 1882 two weekly parts began to be issued. After passing through some critical periods, drastic changes were made in 1906. Publication was then handed over to the firm of Otto von Halem and the editorship to Baron von Vietinghoff-Scheel. On the resignation of the latter in 1918, Dr. Walther Roth was appointed editor-in-chief. In 1920 the usefulness of the journal was increased by the creation of a special section, entitled *Die chemische Praxis*, which is soon to be enlarged. The annual reports on progress, which in some form or other have always been a feature of this newspaper, will henceforth appear as a special quarterly issue entitled ***Fortschrittsberichte der Chemiker-Zeitung über die wichtigsten Gebiete der Chemie und chemischen Industrie.***

In making a plea for the adoption, especially in scientific communications, of the metric units, Prof. R. A. Gortner, of the University of Minnesota, refers in particular to the following expression used by Messrs. H. J. Page and W. Williams, of Rothamsted Experimental Station: "The land is typical strong wheat and bean land which can ordinarily be expected to give a yield of four to five quarters of wheat per acre" (*Jour. Agric. Sci.*, vol. 16, part 4, pp. 551-573). Prof. Gortner was unable to discover exactly how much a 'quarter of wheat' signified. Reference to "Webster's New International Dictionary" shows that 1 quarter, as applied to grain, is equivalent to 8 bushels. In annuals, almanacks, and in books of tables such as the "Smithsonian Physical Tables," the quarter is also defined as equal to 8 bushels. The "Encyclopædia Britannica," under "Acreage and Yield of British Crops," supplies the additional information that the imperial quarter is 480 lb. of wheat, so that the imperial bushel is the same as that in use in the United States, namely, 60 lb. of wheat. Mr. Page has also informed us that in "Recueil decoefficients et d'équivalences," published by the International Institute of Agriculture at Rome, where the metric equivalents are given of all weights and measures, it is stated that 1 quarter = 8 bushels = 2·90942 hectolitres, and that 1 quarter of wheat = 480 livres = 2·17724 quintals. Conversion tables are also available in the "Smithsonian Physical Tables." Mr. Page defends his original expression, stating that the information conveyed thereby is agricultural rather than scientific, and as such is more intelligible to those familiar with British agricultural conditions in its present form. For others, the conversion tables available must suffice while the present unscientific system of British weights and measures remains in common use.

The paper by P. Dunsheath on 33,000-volt cables, which was read to the Institution of Electrical Engineers on Jan. 20, discusses a question which is of the greatest interest at the present time. It is well known that the ordinary high-tension cables for three-phase working, each of which contains three conductors, have in several cases broken down with consequent financial loss and interference with the continuity of supply. This breakdown is generally attributed to air spaces developing in the insulating material. As the electrostatic field is very strong, these spaces get ionised, and this results in the slow destruction and ultimate breakdown of the insulating material. To get over this difficulty, cables are often made with metal sheaths wound round each of the conductors. This makes the electrostatic field in the neighbourhood of the conductors radial to them, and the insulating material has greater strength to resist radial stresses than to resist tangential stresses. The assumption is made that the tangential stress is the dangerous one. We do not think this reasoning is very convincing. Approximate expressions for the electrostatic forces inside a three-core cable can easily be obtained, and they show that the tangential stresses are small. The calculations of the sheath losses, by calculating the tangential and radial eddies separately, may be true, but it wants a more rigorous proof. The experimental results given are of value. It is stated that the introduction of metal sheaths round the conductors enables them to get rid of their heat more readily and thus enables them to carry greater currents. Assuming that the same quantity of insulating material is used in the two cases, this may be true, but the increase due to this cause would be very small.

THE numerous problems that arise in connexion with the working of oil-fields have been studied closely by electricians for many years. About twenty-five years ago the South Russian oil-fields at Baku used electric power. Now practically all the important oil-fields in the world are electrified. An interesting account of several of these installations is given in *A.E.G. Progress* for October, which is published by the Allgemeine Elektricitäts-Gesellschaft of Berlin. The main advantages in electric driving are the saving of the fuel effected and the large reduction in the working costs. Other advantages are that there are fewer breakdowns and that the cost of the necessary mechanical equipment is appreciably reduced owing to the even turning moment of the electric motor. Two years ago the A.E.G. secured the contract for the 25,000 H.P. station required for the Comodoro Rivadavia oil-fields in the Argentine. Careful calculations were made to find out whether Diesel engines, working with either gas or oil, or steam turbines would be the more economical. It was proved conclusively that the turbine scheme was the more desirable, and this has now been completed. The drawbacks to the Diesel scheme were its high capital cost and the high depreciation and interest charges. In addition, there were the higher maintenance costs and a more expensive fuel consumption when the station had only a partial load. The turbines are supplied by water-tube boilers heated by gas- and oil-firing. It is noteworthy that the air required for cooling the generators and ventilating the engine-room passes through special oil-mesh filters. The air in the engine-room is always at a definite pressure above that of the air outside, so that dusty or sandy air, which owing to the nature of the site has to be specially considered, cannot penetrate into the engine-room through the doors and windows. Accounts are also given in this paper of the Baku naphtha industry and of the Roumanian and Galician oil-fields.

THE Department of Scientific and Industrial Research has just issued the Report of the Fuel Research Board for the year 1925 (London, H.M.S.O.; 1*s*. 3*d*. net), including the report of the Director of Fuel Research. At the present time it seems a somewhat belated document, but is interesting as showing the wide range of problems which this organisation touches upon. The experiences with the vertical metal retorts for low temperature carbonisation show that such a problem is largely metallurgical, namely, the production of a cast iron not given to 'growing' at a dull red heat. Considerable space is devoted to the history of and progress made with the Physical and Chemical Survey of Natural Coal Resources, which is rightly regarded as of prime importance to the scientific use of coal in Great Britain, and to the promotion of the export trade, in connexion with which the standardisation of methods of sampling and analysis is also valuable. A memorandum of the Director prepared for the Royal Coal Commission gives an interesting survey of the fuel problem of Great Britain in its general form.

NUMBER 5 of the *Transactions of the Optical Society* for 1925–26 contains Prof. von Rohr's account of the position of the optical industry at the beginning of the nineteenth century and of Fraunhofer's optical work in the early years of the century. Mr. D. Baxandall adds some interesting facts about the ancient glass works at Ratcliff, near the Royal Mint, and the difficulties of Dolland and of Ramsden, his son-in-law, in obtaining optical glass after the closure of those works. At the beginning of the nineteenth century the best instruments appear to have been produced by the English makers, and Voigtlander, before establishing his works in Vienna in 1808, spent some years with London masters. Fraunhofer was engaged as a journeyman optician by a Munich firm in 1807 and by 1809 had attained a directorship of the firm. He aimed at scientific accuracy in his instruments, and found it necessary to learn glass-making himself. By 1813 he had made sufficiently accurate measurements of the dispersion of the glasses available and could calculate the details of an objective so that the grinder had merely to work to data supplied. He also improved the homogeneity of his glasses by having large meltings, and devised grinding and polishing machines and methods of testing his surfaces. Details of some of his instruments are given.

PROF. HENRY E. ARMSTRONG will deliver the Horace Brown Memorial Lecture of the Institute of Brewing in the lecture theatre of the Institution of Electrical Engineers at 8.15 P.M. on Friday, Feb. 25. The Horace Brown Medal will be presented to Prof. Armstrong during the course of the evening.

MR. E. GUY DAWBER, president of the Royal Institute of British Architects, Sir John Reith, managing director, British Broadcasting Corporation, and Prof. G. I. Taylor, Yarrow research professor of the Royal Society, have been elected members of the Athenæum Club under Rule II., which provides for election by the Committee of "persons of distinguished eminence in science, literature, or the arts, or for public services."

THE International Hydrographic Bureau, Monaco, has issued a Circular-Letter (No. 38-H of 1926) upon international uniformity in quarantine signals for ships, the outcome of proposals submitted to the International Sanitary Conference at Paris in May 1926. It is proposed (1) that the colour *yellow* shall be used exclusively for quarantine; (2) that international code flags Q, I, and L shall be used to signify respectively "I have a clean bill of health," "I have not a clean bill of health," "I have (or have had) dangerous infectious disease on board." Another proposal suggests the use of particular lights in definite arrangement for night use. The Directing Committee of the Bureau urges the adoption of these proposals by all governments; the signals are already in very general use.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—A professor of bacteriology in the University of Cairo—Sir H. J. Waring, 37 Wimpole Street, W.1 (Feb. 11). A lecturer in physics and mathematics in the Portsmouth Municipal College—The Secretary, Offices for Higher Education, Municipal College, Portsmouth (Feb. 15). An assistant in the Bradford Natural History Museum—The Town Clerk, Town Hall, Bradford (Feb. 17). An instructress in dairying and poultry-keeping under the Agricultural Education Sub-Committee of the Herefordshire County Council—The Organiser of Agricultural Education, Agricultural Education Office, High Town, Hereford (Feb. 19). An assistant inspector in the Department of Fisheries, Irish Free State—The Secretary, Civil Service Commission, 33 St. Stephen's Green, Dublin (Feb. 19). A professor of education in Victoria University College, Wellington, New Zealand—The High Commissioner for New Zealand, 415 Strand, W.C.2 (March 1).

Our Astronomical Column.

COMETS.—Another new comet, 1927 *b*, is reported from South Africa. It is of the eighth magnitude and was found by Mr. William Reid, of Cape Town, Jan. $26^{d}\ 19^{h}\ 43^{m}{\cdot}5$ U.T. in R.A. $22^{h}\ 30^{m}\ 40^{s}$, S. Decl. 57° 49′, daily motion $+44^{s}$, S. 4′.

This is Mr. Reid's sixth cometary discovery, in addition to his detection of d'Arrest's periodic comet in 1923. He has lately been in poor health, so astronomers will be glad of this evidence of his ability to resume observing.

We are already assured of four perihelion passages in 1927 (Neujmin, Blathwayt, Comas Sola, Reid, assuming that it did not pass perihelion last year). There is little doubt that comets Grigg-Skjellerup and Pons-Winnecke will be added to the list in a month or two.

M. J. Polak has just published his definitive orbit of comet 1893 I. Brooks in the *Annals of Moscow Observatory*, vol. 8, No. 1. The comet was observed from Nov. 19, 1892, until Mar. 11, 1893. The following hyperbolic orbit was found:

$$\begin{array}{rl}
T = & 1893 \text{ Jan. } 6{\cdot}52847 \text{ Berlin M.T.} \\
\omega = & \left.\begin{array}{l} 85^\circ\ 13'\ \ 5{\cdot}4'' \\ 185\ \ 39\ \ 16{\cdot}6 \\ 143\ \ 51\ \ 28{\cdot}3 \end{array}\right\} 1893{\cdot}0 \\
\log q = & 0{\cdot}077436 \\
e = & 1{\cdot}001586
\end{array}$$

(with Ω and i on the second and third lines of the bracketed group)

The residuals with a parabolic orbit are not very much greater than those with the hyperbolic one, so the departure from a parabola is not quite demonstrated.

SOLAR RADIATION.—In *Smithsonian Miscellaneous Collections*, vol. 78, No. 5, Dr. C. G. Abbot answers criticisms advanced by Moll, Burger, and Van der Bilt (*Bulletin of the Astronomical Institutes of the Netherlands*, No. 91, 1925) with respect to his investigations on the distribution of energy over the sun's disc. The observations were made primarily for the purpose of testing the suspected variability of the solar radiation, and only differential accuracy was required. Abbot proceeds to show that even as regards absolute values the errors of the drift-curves do not exceed 0·3 per cent. at a distance of 0·95 of the sun's radius. Observations were not carried nearer the limb because of inherent difficulties, and also because they were not required for his immediate purpose. He points out that his critics' statement regarding accidental error rests on one curve made at Washington prior to 1908, though the work went on under highly satisfactory conditions at Mt. Wilson from 1913 until 1920. Abbot considers, therefore, that the Dutch investigators have drawn a too hasty conclusion in criticism of his results, and suggests ways in which two independent investigations might give different results unless certain observational details are made strictly comparable. He also mentions that, whereas he used a solar image of 40 cm. and 20 cm. in diameter, the Dutch observers used one of only 3 cm. Possibly further experiments proposed by the latter may clear away the discrepancies.

STATISTICAL PROPERTIES OF GALACTIC CEPHEIDS.—In the *Astrophysical Journal*, vol. 64, p. 149, J. Schilt discusses the proper motions, periods, and magnitudes of the Cepheid variables, and their galactic distribution. In the Sagittarius-Aquila region the period of maximum frequency is about 7 days, but in the remaining regions it is considerably shorter. The portion of the galaxy directly opposite the Sagittarius-Aquila region possesses comparatively few Cepheids, and the frequency curve of periods shows no decided maximum. There is, however, a slight indication of a maximum at an even shorter period (about 4½ days), in which case this region would closely resemble the small Magellanic cloud. Results based on the data at present available seem to indicate a discontinuity in the absolute magnitudes and other characteristics of Cepheids, at the stage corresponding to a period of about 10 days. This suggests the division of the Cepheids into two classes; but the data are too uncertain to warrant any definite pronouncement, and attention is directed to the urgent need for additional work on radial velocities and proper motions. This necessity is further emphasised by the considerable discrepancy which exists between the absolute magnitudes of Cepheids deduced from the parallactic motions of 13 Boss stars and from the motions of 28 fainter stars. The mean absolute magnitude of the former is −2·5, and of the latter +1·3.

Research Items.

Colour Selection among Negroes in the United States.—An interesting investigation in sexual selection among negroes in the United States has been carried out by Mr. Melville J. Herskovits, who describes his results in vol. 12, No. 10, of the *Proceedings of the National Academy of Sciences of the United States*. It appears that a definite type of selection, based largely on skin colour, is practised by American negroes in many aspects of their life, but especially in marriage. Students who were being measured at Howard University were asked to state whether their mother or father was the lighter. In 30·3 per cent. of the cases the father was the lighter, in 13·2 per cent. the parents were about the same, and in 56·5 per cent. the mother was the lighter. Later 400 negro families were measured in the Harlem District of New York City. Of 176 married couples available for this investigation, 29·0 per cent. showed a lighter father, 14·5 per cent. the same colour in both parents, and 56·5 per cent. a lighter mother. Further analysis shows that the men who are party to the matings are darker than the females, though in unselected series of males and females there is practically no sex difference in colour. It would therefore appear beyond question that there is a social selection in operation through the tendency of males to marry lighter females. Selection on the basis of other negroid traits, thick lips or broad noses, does not appear to be operative. If this selection on the basis of skin colour continues, as the children of each generation will tend to be darker than the mother, the American negro population will become nearer the negro type, since the relative amount of negro blood will be increased, though there is too much Indian and white blood in it to permit reversion to the pure negro type.

A Vitrified Fort at Dunagoil, Buteshire.—Excavations carried out at a fort at Dunagoil, Buteshire, from 1913 until 1915 and again in 1919, have yet to be described in detail; but a summary of the results has been published by Mr. L. M'Lellan Mann, in the *Transactions of the Buteshire Natural History Society* for 1925. The exploration of the fort is not quite complete. Vitrified forts are so called from the fact that the rubble core of the walling has been intentionally burned to form a hard vitrified mass to which the stones of the external walls adhere, thus giving great strength and power of resistance. Such structures are almost entirely lacking in fortified sites outside Scotland, where they occur chiefly near the seashore, ranging from the Solway up to the central west Highlands and thence in a belt across country to Inverness-shire as well as on a portion of the north-east coast. Dunagoil fort is entirely pre-Roman and was occupied from about 200 B.C. until A.D. 100. It is situated on a knife-edge ridge at the south end of the island of Bute. The construction of a crescentic wall on the less precipitous side, in order to give a fairly secure platform for the habitations of the occupiers, caused an accumulation of refuse which afforded a rich harvest for the excavators. The walls of the building were some twelve feet thick. They were built in stages of two or three feet, the rubble being burned at each stage until a height of fifteen feet had been reached. The rampart probably had two parapets and the fort two entrances, protected apparently by massive timber doors held by wooden bars which, when not in use, lay in horizontal holes in the interior of the walling. The objects found, which are very fully illustrated, included stone axes, hammers, knives, anvils, and other tools of stone, saddle querns imperfectly converted into rotary querns, utensils and personal ornaments of imported soapstone and lignite, an inferior hand-made pottery, many objects of bone and antler including a peculiar pin or bodkin, square in section with ornamented sides; bracelets of jet, lignite, and glass, the last-named multicoloured, and a large variety of iron objects.

Marine Biology at the Isle of Man.—The report of the Biological Station at Port Erin, Isle of Man (fortieth annual report of the former Liverpool Marine Biology Committee, now the Oceanography Department of the University of Liverpool), drawn up by Prof. J. Johnstone, indicates satisfactory progress in all directions. The fish cultural work carried out for the Manx Government shows a good average yield of young plaice, and the lobster hatching still improves, the numbers being considerably higher than before. More than a million plaice larvæ and more than six hundred lobsterlings, besides a large number of younger stages, were liberated into the sea. In the Bio-Chemical Laboratory Mr. J. R. Bruce has completed his investigations into the seasonal variations of the gaseous metabolism of the common mussel (*Mytilus edulis*), and the results have been published in the *Biochemical Journal*. He also continues his interesting researches on the metabolism of shore-living dinoflagellates. In the appendix, Mr. A. Scott describes the plankton of the spawning ponds and its seasonal variation. Mr. H. C. Chadwick, in his "Natural History Notes," mentions the occurrence of the diatom *Rhizosolenia robusta*. This is interesting, as the usual northerly limit of this species is the English Channel. It is to be noted, however, that in the last two years this diatom has been particularly abundant in the autumn at Plymouth. Being such a large form it should be of more than usual importance for feeders on the phytoplankton. A list of publications based on work done at the Laboratory shows a number of important papers dealing with fishery problems, physiology, and natural history, and includes Prof. Johnstone's book, "A Study of the Oceans." In the introduction to the report it is stated that the Laboratory is little used by visitors in the late summer, and a glance at the list of research workers shows this very plainly. It is curious that there is not more eagerness to undertake studies in these important months.

The Flora of the Talysh.—Under the above title Mr. A. A. Grossheim, botanist of the Tiflis Botanical Gardens, has recently published an interesting volume (273 pp., 16 plates, map; text in Russian, summaries in English and in Turkish) dealing with the vegetation and flora of the little-known country at the south-western corner of the Caspian Sea. The author gives vivid and detailed descriptions of various types of vegetation, ranging from that of marshes (which harbour the endemic water nut *Trapa hyrcana* G. Wor.) to the deserts, and from lowlands forests of *Parrotia persica* and *Zelkowa carpinifolia* to the rocky, woodless, semi-desert formations of higher mountains. An analysis of the flora enables the author to arrive at some interesting conclusions as regards the history of the vegetation of the region in question. In Tertiary times the country was covered with forests of tropical character, and genera like Albizzia, Gleditchia, etc., have survived even until the present day. Later on, with the advent of a drier period and the development of a powerful centre of xerothermic flora in Persia, that flora (Hyrcanian) began to invade Talysh from the south, while about the same time an invasion began of the Mediterranean flora from the west. Further intensification of the dry and hot conditions resulted in the appearance of numerous endemic xerothermic forms, which are clearly younger than the actual autochthonous elements. The glacial period, which brought great changes to the flora and vegetation of other parts of the Caucasus, left no traces whatever in the flora of Talysh. Later influences were of little importance, and only the activity of man was responsible for the introduction with the culture of rice of a fair number of typically tropical lowland plants, which misled previous students of the flora to conclude that it is essentially sub-tropical in character, whereas it is not so. A formal division of the country into botanico-geographical districts concludes the memoir.

Field Trials with Cotton.—M. A. Bailey and T. Trought, in Technical and Scientific Service Bulletin No. 63, report on experiments conducted by the staff of the botanical section of the Egyptian Ministry of Agriculture, under the ægis of the Cotton Research Board, to determine the amount of variability that might be expected in field trials with cotton, and the technique which would best reduce the experimental error. For comparative trials, it is recommended that no paths should be left between the beds, but that adjacent ridges should be uprooted at picking time. Variety beds are best repeated ten times, while all trials should be extended over a period of at least three years. The most suitable form for the beds is that of long, narrow strips, situated along the lengths of the ridges to facilitate sowing, the area being one-fifth feddan where possible (1 feddan = 4200 sq. m. or 1·038 acres approximately). The results should be computed by the method of differences. The procedure to be followed in the event of insufficient land or seed is also dealt with. A special feature of the report is the inclusion of various frequency curves, charts, and tables, which allow of a more exhaustive analysis of the data by other workers if desired.

Juniper in Norway.—The half-yearly issue (Oct. 1926) of the *Transactions of the Royal Scottish Arboricultural Society* opens with an interesting article on "The Nordfjord of Norway," a long arm of the sea extending 60 miles eastwards from the North Sea, with several subsidiary fjords. The author, Mr. F. R. S. Balfour, treats of both the agricultural and forestry aspects of the country, showing the interdependence of the population on the two pursuits. An interesting item in this article deals with the use of the juniper, which grows into a small tree of 30 feet high, for fencing work. Fences are almost exclusively made of this wood, which lasts as long in the ground as the North American *Juniperus virginiana*. The author saw a fence erected one hundred years ago, and still perfectly serviceable.

Coal in South Australia.—The Mining Review of the South Australian Department of Mines for the half-year ending June 30, 1926, recently issued, contains an interesting summary of what is known regarding the coal and lignite resources of South Australia. Apparently the only true bituminous coal so far discovered lies at very considerable depths covered with highly water-bearing Tertiary sediments, which appear to render its economic exploitation impracticable. There are three occurrences known of sub-bituminous coal, apparently of Triassic age; this coal appears to be only of moderately good quality, the moisture as mined ranging from nearly 9 per cent. to more than 30 per cent., and the ash from more than 6 per cent. to more than 18 per cent.; a sample which has been tested gave 7460 B.Th.U. per lb. as mined, a figure which compares very unfavourably with ordinary bituminous coal. A number of occurrences of Tertiary lignite are known; apparently the only attempt at actual mining has been done in the Moorlands field, and the coal has been extensively tested, but the results do not appear to have been satisfactory. It would appear that up to the present, imported coal can be used to better economic advantage than any of the mineral fuels hitherto discovered in South Australia.

Granite Domes of Vredefort and Arran.—The recent monograph on the Vredefort Mountain Land, by Hall and Molengraaff, has aroused world-wide interest among geologists, mainly because of the wonderful and almost incredible structure of the sediments on the flanks of the granitic dome which lies in the heart of the region. The sediments have not only been heaved up but they have also been carried through the vertical and overturned. For this reason, Hall and Molengraaff rejected the idea that the structure might be due to the upward surge of magma. Their problem is further complicated by the possibility that the Vredefort granite is, in the main, older than the overtilted sediments; and their tentative conclusion is that the balance of evidence favours the conception of centripetal pressure as the cause of the dome. In the *Geological Magazine* for November, Mr. E. B. Bailey summarises the evidence, and points out in detail the striking analogies presented by the granite dome of North Arran. Although in Arran the surrounding schists are rarely overturned, the evidence is conclusive that they were powerfully uplifted by the intrusion of the granite complex, and that the upheaval was accompanied by an outward movement that succeeded in overturning a boundary of Old Red Sandstone. Mr. Bailey points out that an upward magmatic push must develop an outward centrifugal push. Combining this tectonic necessity with the evidence of its existence elsewhere, and the difficulty of imagining a mechanism to explain the suggested centripetal pressure, he strongly advocates central upheaval by upward magmatic pressure accompanied by centrifugal pressure as the explanation of the updoming and back-tilting of the formations bordering the Vredefort granite.

Physiography of the Virgin Islands.—The New York Academy of Sciences has nearly completed the publication of its detailed "Scientific Survey of Porto Rico and the Virgin Islands." One of the most recent parts to appear is vol. 4, pt. 1, which deals mainly with the physiography of the northern Virgin Islands, British and American, by Messrs. H. A. Meyerhoff and J. F. Kemp. The conclusions of most interest are those with regard to the submarine platform from which the islands arise. This has generally been accepted as due to marine erosion in Pleistocene times, when the sea-level was lowered in tropical latitudes, but Mr. Meyerhoff is convinced, after a detailed study of its features, that river action has played the chief part in its formation. He found numerous remnants of horizontal coastal plain deposits, presumably of Tertiary age, lying on the submerged platform. These are evidence of river erosion before Pleistocene time. The action of the waves in Pleistocene times was effectual, if at all, only in modifying the surface. The evidence is discussed at length in the monograph, which is well illustrated with maps, diagrams, and photographs.

Rainfall of Moravia.—Some relation between the amount of precipitation and altitude above sea-level are discussed by Dr. Fr. Rikovsky in Part 78 of *Publications de la Faculté des Sciences de l'Université Masaryk*. On the plateau of Moravia the rainfall is 530 mm. at 200 m. and increases some thirty-three millimetres for every 50 metres up to 650 m., above which the increase grows rapidly. In the eastern or drier part of the Moravian Carpathians the fall is 561 mm. at 200 m., and the increase up to 600 mm. is much more rapid than on the plateau, while at higher elevations it is much slower. The explanation is that on the Carpathians the air currents, owing to the steep slope, are forced to rise abruptly, and so lose much of their humidity at low altitudes, while on the plateau the rise is gradual and the loss of moisture steady. In the western part of the Moravian Carpathians, precipitation is much greater and increase is steady and continuous. Statistical tables and diagrams show these relationships.

Resistance of Metals at Low Temperatures.—Supplement No. 58 to the Communications from the Physical Laboratory of the University of Leyden consists of a collection of all the known data concerning the electrical resistance of metals at temperatures below −80° C. made by the late Prof. Kamerlingh Onnes and Dr. W. Tuyn. A large proportion of the data comes from the Leyden Laboratory, but in all cases references are given to the original sources. 42 pages of tables and curves are devoted to the influence of temperature, 4 to that of pressure, and 28 to those of impurities, heat treatment, and other factors. Of the large number of formulæ which have been suggested for the relation between the resistivity and the temperature only a few are noted. For monatomic metals the resistivity seems to be proportional to the product of the absolute temperature and the atomic heat at constant pressure. There is some divergence of opinion as to the validity of a law of 'corresponding resistances' which has been suggested.

Impact Tests of Steel at Low Temperatures.—Impact tests have been made by Ryonosuke Yamada (*Sci. Rep.*, Tohoku Imp. Univ., Ser. 1, vol. 15, No. 5, Nov. 1926) on a large number of steels at temperatures from that of the room down to that of liquid-air. The main results obtained are: In general the impact value falls as the temperature is lowered, though in a dead-mild steel, for example, this value actually rises down to about −40° C., when it suddenly falls to almost zero. Quenched and tempered steels, or any steels with a sorbitic structure, are much tougher at low temperatures than are pearlitic steels. The addition of nickel and chromium retards appreciably the increase of brittleness as the temperature is reduced. As the latter falls there is a progressive tendency for the fracture produced to pass around, instead of through, the crystals, and the fracture in pearlite to take place in all directions irrespective of the orientation of the lamellæ.

A New Phenomenon in the Abnormal Discharge.—When the distance between the electrodes is decreased in a tube in which a normal discharge is passing, the potential difference between the electrodes gradually decreases, until the anode approaches so close to the cathode inside the Faraday dark space that some of the fast primary electrons from the cathode reach the anode, and then the potential falls somewhat rapidly. If the distance between the electrodes is still further decreased, the potential remains practically constant until the anode penetrates approximately to the middle of the negative glow, when it increases very rapidly, owing to the fact that the fast primary electrons and the secondary electrons they produce have not sufficient space in which to form considerable numbers of positive ions. In investigating this phenomena during the passage of an abnormal discharge, Guntherschulze (*Zeit. fur Phys.*, 40, 414, 1926) found that the higher the applied potential, the sharper did it fall just before the rapid increase due to the close proximity of the electrodes occurred. The cause of this phenomenon is found to be that the fast primary electrons from the cathode are able to form larger numbers of positive ions in the layer of gas and water vapour absorbed on the surface of the anode than they are able to produce in the body of the gas in the tube.

Isolation of Element 61.—In their first paper on the isolation of element 61 (see Nature, Dec. 4, 1926, p. 820, and Jan. 1, 1927, p. 27), Rolla and Fernandes stated that a sealed packet containing their results and a photograph of the X-ray absorption spectrum was sent to the Royal Academy of the Lincei so early as June 1924. In order to prove their claims to be the first to isolate the element, these preliminary results have been published in the November issue of the *Gazzetta Chimica Italiana*. Rolla and Fernandes have proposed the name 'florentium,' with symbol 'Fr,' for this element in honour of the University of Florence, where the research was carried out.

The Attempted Change of Mercury into Gold.—The News Edition of *Industrial and Engineering Chemistry*, dated Dec. 10, contains a detailed account by Sheldon and Estey, of the New York University, of attempts to change mercury into gold by the method used by Miethe. The actual type of mercury arc lamp used by Miethe, which was obtained from Germany, as well as other lamps, were used, and the experimental conditions were reproduced so far as possible. Details of several experiments are given, but in no case was any amount of gold greater than 0·005 milligrams (the limit of detectability) produced. Various deposits were produced in the lamps, but these never contained any gold, and the residual mercury was also found to be free from that metal.

Ignition Temperatures of Solid Fuels.—In connexion with the subject of spontaneous combustion, the study of the ignition temperatures of fuels is of great importance. K. Nakamura and A. Shimomura have improved the ordinary form of apparatus, and have published the relative ignition temperatures of twenty-two kinds of solid fuels, including lignites, bituminous as well as anthracite coals of oriental origin, semi-coke, metallurgical coke, and wood charcoal, in the *Memoirs of the Kyoto College of Science*, Series A, Nov. 1926. Previous work by Wheeler has been confirmed, and it has been found that volatile matter and ash-content have a decided influence on the ignition temperatures of the fuels.

Mechanism of Kolbe's Electrosynthesis.—There are two theories as to the exact nature of the change by which ethane is produced at the anode during the electrolysis of a solution of potassium acetate. According to the 'oxidation theory,' the discharged anions react with water to give the acid which is oxidised by atomic oxygen to give the synthetic product, while the 'discharged ion' theory supposes that two discharged ions unite directly. A paper in the *Journal of the Chemical Society* for Dec. 1926, by D. A. Fairweather and O. J. Walker, describes some work on solutions of acetates and propionates which was carried out in order to obtain further data bearing on electrosynthesis. The results show that the synthesis can only be accounted for on the 'discharged ion' theory.

The Technique of Vitamin Assay.

When it was found that a diet of pure protein, fat, and carbohydrate with salts and water was incapable of maintaining life in animals unless small quantities of certain natural foods were added, quantities too small to supplement the energy value or the content of the diet in the other known constituents, the foundation was laid upon which has been built in the last fifteen years a vast store of knowledge about the properties and occurrence of these unknown accessory food factors or vitamins. At first investigators were concerned with the qualitative distribution of each vitamin, as it was discovered: only later was attention directed to its quantitative estimation in different sources, as the methods of assay became more perfected. These lines of approach to an accurate knowledge are in use to-day, when a new vitamin is discovered, as is shown by the work of Evans and his collaborators on Vitamin E, or the reproductive factor.

It is obviously important from the point of view of dietetics and medicine that the amounts of the vitamins in different food and medicinal products should be accurately known. Such knowledge can be obtained at present only indirectly, since the vitamins have not yet been isolated in pure form, and any fallacies inherent in such a method of assay are greatly enhanced by the fact that, in general, living animals must be used for the test. Hence improvements in technique relate to the use of a standardised animal, bred especially for the purpose, and placed on a diet either deficient solely in the factor to be assayed, or so designed as to enable the observer to obtain a clear-cut response on the part of the animal or even of a given tissue, when the missing factor is added to the diet. Recent improvements in technique are especially noticeable in the case of Vitamin A or the growth-promoting factor, and Vitamin D or the bone-calcifying factor. A further interesting development is the use of a colour test, which can be used for the quantitative estimation of Vitamin A, and bids fair in time to replace the laborious growth test on animals altogether.

The details to be followed in the production of a standard breed of rats for the assay of the fat-soluble Vitamins A and D are discussed by H. Chick and H. H. Smith and H. Chick (*Biochem. Jour.*, 1926, vol. 20, pp. 119, 131). The authors were led to their researches by finding unexplained irregularities in the behaviour of the young rats when placed upon the standard basal diet deficient in fat-soluble vitamins. In general, better growth and calcification of the bones were found in summer and autumn than in winter and spring. Neither the degree of illumination to which the animals were exposed nor the constituents of the standard deficient diet were found to be implicated in this variability. It may perhaps be mentioned here that the diet largely used in Great Britain consists of inactivated caseinogen, starch, a hardened vegetable oil, salts and water, together with 'marmite' and lemon juice to supply Vitamins B and C respectively. The caseinogen is inactivated, *i.e.* any fat-soluble vitamins present are destroyed by heating it to 120°-130° C. for thirty-six hours.

Examination of the diet given to the stock-breeding rats, however, disclosed the possibility of serious variations in the amount of Vitamin D, with smaller changes in the case of Vitamin A, dependent upon seasonal alterations in the content of these vitamins in the fresh milk of the diet. It is well known that the store of fat-soluble vitamins in young rats depends on the previous diet of the mother, especially during pregnancy and lactation. Hence the diet of the stock animals should contain, if possible, a constant and sufficient, but not excessive, quantity of fat-soluble vitamins. This ideal was approached by replacing fresh milk with a dried winter milk towards the end of pregnancy and continuing its use during lactation, and, in the case of the young, during the period elapsing between weaning and placing on the deficient diet. Earlier use of this milk in the mother's diet lowered the store of vitamins too much, so that it became difficult to rear the young. The other constituents of the diet, bread, whole cereals and seeds, fresh raw vegetables, and marmite, with meat twice a week, provided a steady supply of Vitamin A; so that the irregularities in the young rats were probably chiefly caused by variations in their stores of Vitamin D.

The fact that the latter vitamin may be responsible for variations in growth has only recently been realised, with the definite demonstration that Vitamins A and D are distinct accessory food factors. Its importance is demonstrated by the following considerations: the original standard diet deficient in fat-soluble vitamins is deficient in both: cessation of growth may then be due to exhaustion of either, and resumption of growth, on supplementing the diet with a material containing them again to either, or both, of the vitamins present. Hence titrations of Vitamin A may be considerably affected by the presence or absence of Vitamin D from the diet or body of the experimental animal.

This question has been carefully examined by J. C. Drummond, K. H. Coward, and J. Hardy (*Biochem. Jour.*, 1925, vol. 19, p. 1068). The authors found that irradiated cholesterol, which is now known to have marked antirachitic potency, that is, to contain Vitamin D, can, under certain conditions, cause resumption of growth in rats on the standard-deficient diet. But the authors show that this does not mean that by irradiating cholesterol, Vitamin A is generated. In the first place, the colour reactions of irradiated cholesterol are not those usually associated with Vitamin A (this subject is discussed more fully below); secondly, the addition of the irradiated material to the diet only produced resumption of growth when given soon after growth had ceased; later it was without this effect; and thirdly, the resumption of growth was only temporary and could not be maintained by increasing the dose, although small doses of cod-liver oil prevented the decline in weight, in fact, allowed growth to continue. The authors conclude that the store of Vitamin A in the animal is only available in the presence of Vitamin D, and that the irradiated cholesterol supplies the latter and not the former.

Hence in comparing the growth-promoting powers of two materials, one of which contains Vitamins A and D, and the other Vitamin A only, an erroneous idea of their relative contents in Vitamin A can easily be obtained if the animals at the time are suffering from a simultaneous deficiency of Vitamin D. With the former supplement, growth would be dependent on both vitamins together; with the latter, little growth would probably be seen, unless the animals still had a store of Vitamin D, although the Vitamin A content of both materials might be the same. The important conclusion is therefore reached that for the accurate assay of Vitamin A, Vitamin D must be always present in the basal diet. This can be ensured by the addition of irradiated cholesterol to the diet, or by feeding it separately as a daily supplement dissolved in liquid paraffin (Drummond *et al.*), or perhaps more conveniently by using an irradiated hardened vegetable oil as one of the constituents of the diet (H. Chick and M. H. Roscoe, *Biochem. Jour.*, 1926, vol. 20, p. 632). Drummond excludes fats altogether from his latest standard diet, replacing them with starch, but other observers continue to use a diet of the type mentioned above. If the animals are given a diet deficient only in Vitamin A, they continue growing for a longer period than when Vitamin D is also absent; but when growth ceases, a decline in weight rapidly sets in and the supplement containing Vitamin A must be quickly given, if death is to be prevented.

So far we have considered the assay of Vitamin A by means of animal experiments. The difficulties and the time involved lend importance to an alternative possible method, such as a colour test, which can be performed quickly and accurately in a test tube. Two such have been recently described as specific for Vitamin A: the transient blue colour produced by arsenious chloride (Rosenheim and Drummond) and the stable red colour produced by pyrogallol in the presence of a light petroleum solution of trichloracetic acid (W. R. Fearon, *Biochem. Jour.*, 1925, vol. 19, p. 888). The latter, which seemed likely at first to be of great use, was modified by S. G. Willimott and T. Moore (*ibid.*, 1926, vol. 20, p. 869): resorcinol was used instead of pyrogallol, and a saturated solution of benzoyl peroxide in toluene was added to hasten the reaction, the trichloracetic acid being also dissolved in this solvent.

Preliminary experiments showed that the colour was produced by those substances, chiefly oils, in which the presence of Vitamin A is generally accepted, and not by others from which this vitamin is absent. However, a more extensive study by O. Rosenheim and T. A. Webster (*Lancet*, 1926, vol. 2, p. 806) has demonstrated that the test is not specific for Vitamin A: thus, on saponification of an active oil, Vitamin A remains in the unsaponifiable fraction, but the chromogen giving Fearon's reaction passes into the soaps formed, being associated with the unsaturated fatty acids. Again, only fish liver oils give the reaction, whereas the liver oils of birds and mammals contain Vitamin A: body fat may react positively, but negatively to the arsenious chloride reagent. In a biological test, a sardine oil, giving Fearon's reaction, was found to be devoid of the growth-promoting factor, whereas pig's liver fat, although reacting negatively with Fearon's reagent, yet gave as good growth as cod-liver oil—even when only half of the dose of the latter was used. In all cases vitamin A and the colour reaction with arsenious chloride were found to occur together, in fact, the latter appeared to give a depth of colour roughly proportional to the amount of vitamin disclosed by a growth test. Hence it may be concluded that the colour given by Fearon's reagent is due to some other constituent of the oil than Vitamin A. On the other hand, the arsenious chloride reaction appears to be specific, so far as our present knowledge goes. The drawbacks to the test are the transient nature of the blue colour produced, and the fact that the reagent cannot be used with a solvent.

F. H. Carr and E. A. Price, and T. T. Cocking and E. A. Price have therefore examined a large number of other compounds with the view of selecting a more satisfactory reagent (*Biochem. Jour.*, 1926, vol. 20, p. 497; *Pharm. Jour. and Pharmacist*, 1926, vol. 107, p. 175). At first the substitution of arsenious chloride by a saturated solution of trichloracetic acid in chloroform, as suggested by Rosenheim and Drummond, gave promise of satisfying the necessary requirements, but it was found that the colour production depended on the presence of an impurity in the acid, probably phosgene. The authors finally selected a 30 per cent. solution of antimony trichloride in B. P. chloroform as the most satisfactory reagent so far found: it can be used with a 20 per cent. solution of the oil under test in chloroform, enhancing the accuracy of measuring small quantities of oil. Moreover, the blue colour lasts sufficiently long for a match to be made against the standard glasses of a Lovibond tintometer, and is not interfered with by traces of water or alcohol in the reagents. The colour formed always contains traces of yellow and sometimes also of red.

The real problem which now faces investigators is whether the colour test always gives the same value as the growth test, when both are carried out on a large number of different oils. Some preliminary experiments carried out by S. W. F. Underhill (*Biochem. Jour.*, 1926, vol. 20, p. 500) lend hope that this parallelism may be invariably found, in which case the biological assay, with its difficulties of animals and time, may be rendered unnecessary, being replaced by the much shorter and probably more accurate colour test.

The titration of Vitamin D or the bone-calcifying antirachitic factor still requires the biological method. Moreover, rickets is not produced in rats on a diet deficient only in fat-soluble vitamins. Although the bones contain less calcium than normally, the picture is one of osteoporosis, so that such a diet is not suitable for this assay (H. Chick and M. H. Roscoe, *v. sup.*). But if the diet is deficient in phosphorus also, rickets occurs. Two such diets have been widely used: one was described by Sherman and Pappenheimer, and consists of patent flour with the addition of a few salts; the other we owe to McCollum, its chief ingredients being wheat, maize, gelatin, and wheat gluten with a few added salts. Rosenheim and Webster (*Biochem. Jour.*, 1926, vol. 20, p. 537), using the former, found that sometimes the control animals failed to develop rickets and traced this irregularity to a small quantity of fat present in the patent flour, which could become 'activated' if the flour was exposed to light. They therefore recommend an extraction of the flour with ether at room temperature for a short period, before it is used in the diet.

The degree of calcification of the bones on these diets can be determined radiologically, histologically, or by chemical analysis. Improvements in the presentation of results by the last method are described by Chick and Roscoe (*Biochem. Jour.*, 1926, vol. 20, p. 137, and with V. Kovenchevsky, *ibid.*, p. 622). More clear-cut results are obtained if, in addition to the ash, the fat of the bones is also estimated. Omission of this precaution may suggest that a substance under test has improved the calcification slightly, whereas it has only reduced the fat content, possibly by improving the nutrition of the animals quite apart from its content in Vitamin D, if any is present at all. Normal bones contained about 2 per cent. of fat, rickety 4 per cent., and osteoporotic 10 per cent.: the ash content respectively was found to be 34 per cent., 11 per cent., and 25 per cent. for comparable bones. The authors suggest that the ratio of the ash to the organic residue (that is, the difference between the weight of the bone and the sum of the weights of water, fat, and mineral constituents) may give a useful index of the degree of calcification and of rickets. Normally it is about 1·5, in osteoporosis 0·9–1·2, and in rickets 0·4–0·8.

The more accurate the methods of assay, the better is our knowledge of the value of different food or medicinal products, and the greater is the hope of developing methods for the isolation of the accessory food factors in a pure form.

Tropical Cyclones of the Pacific.

By E. V. Newnham.

Reference was made in a recent article on "The Tropical Cyclone" (Nature, Oct. 9, 1926) to the need for a more complete knowledge of the meteorological conditions in the regions where these storms form, in order to test the correctness of the various theories of the origin of cyclones that have been brought forward at different times. It might have been added that our knowledge is very incomplete even as regards the frequency of their occurrence, the paths which they follow, and the length of life of individual storms, and this is particularly true for the Pacific Ocean. A new work has recently been published, which fills up a few of the gaps in our knowledge.[1] The materials for this work were collected in 1921–1922, when the author spent a year in visiting tropical Oceania and the Far East in order to gather information about cyclones at first hand from resident white officials; he also visited the Meteorological Bureau of the Australian Commonwealth and the Japanese Marine Observatory, as well as various other meteorological centres in the East, in order to study local synoptic weather charts and to discuss his subject with those who have made a special study of the cyclones of those regions.

It appears from Visher's work that, in defining the two remote eastern areas of cyclone-formation, it would have been better not to have restricted the eastward extension of those areas, for although it may be true that more cyclones occur in the western than in the eastern half of the Pacific, many undoubtedly occur near the western coasts of America both north and south of the equator; so many must occur unrecorded in the Western Pacific, unrecorded because of the small number of islands inhabited by educated white men and because of the small number of ships that pass westwards beyond American coastal waters, that an accurate estimate of their average annual number and of their distribution is at present impossible. Visher, indeed, lays great stress on the under-estimation that has been made of the number of storms over the tropics as a whole. If attention is not confined to the most violent and destructive storms, the season of cyclonic activity expands from the summer and autumn to the whole year, and, judging from those regions near the western border of the Pacific for which reasonably detailed synoptic charts are available, for example, the regions around Australia and Japan, the annual number must be very large. Of these a considerable proportion appear to pass out of the tropics, and, by the large exchange of air between tropical and temperate latitudes to which they give rise, exert a big influence upon the weather of both zones, and upon the general circulation of the atmosphere of the whole earth.

The idea that tropical cyclones are of rare occurrence appears to have been held by many meteorologists, and has probably arisen because, on the average, only a small proportion of the total area within the tropics is affected annually by winds of hurricane strength, and a large part of this proportion is open ocean traversed only occasionally by ships. In considering the exchange of air between the tropical and temperate zones, the numerous lesser systems of low pressure are probably, in the long-run at least, as important as the relatively few destructive storms. Visher gives a table of annual frequencies of recorded tropical cyclones which is reproduced here. It should be noted that, in view of the large number of storms and disturbances that are not recorded, the figures are intended as conservative estimates, much below the true totals.

Average Annual Frequencies of Recorded Tropical Cyclones and Cyclonic Disturbances.

	Severe Hurricanes.	Lesser Hurricanes and Cyclones.	Cyclonic Disturbances
Western North Pacific (110° to 140° E.) .	10	20	50
Central Pacific (140° W. to 140° E.) . .	2	4	..
Eastern North Pacific (E. of 150° W.) .	2	3	..
Western South Pacific (130° W. to 160° E.)	5	10	10
Australian Region (110° E. to 160° E.) .	5	8	10
South Indian Ocean	8	5	..
Arabian Sea	2	2	..
Bay of Bengal	2	6	> 2
North Atlantic	3	2	> 2
Totals . .	39	60	> 74

These give an annual total for all classes of cyclone of more than 173.

Two other points of particular interest that are brought out in the paper under notice are:

(1) The unexpectedly large number of cyclones that occur within 8° of the equator in the Pacific, especially in the neighbourhood of the East Indies.

(2) The apparent absence of any kind of direct relationship between the number of cyclones that occur in the Pacific and the physical state of the sun, as revealed by the number of dark spots that are visible.

With regard to the first point, two cases of cyclones originating not more than 4° from the equator in the North Indian Ocean during the period 1900–1912 have been recorded.[2] Visher was informed by T. Okada, Director of the Japanese Imperial Marine Observatory, that the meteorological conditions at Jaluit (lat. 6° 8′ N., long. 170° E.) indicate typhoons west and south-west of that island, and in a table giving particulars of the place of origin of typhoons that were first reported within 8° of the equator, Visher gives one in latitude 4° N., and several in latitude 5° N. These cases are interesting in that they show that although some deflexional effect of the earth's rotation is necessary to prevent air from flowing directly into a centre of low pressure and so filling it up, the amount need only be very small.

The second point mentioned above requires little comment. All Visher's ingenuity in handling the available statistics, so as to bring out any connexion that there may be, gives negative results. Although several earlier investigators have claimed that there is a connexion, it appears very unlikely that there is a simple direct relationship, when it is remembered that the variations of the solar 'constant' of radiation between times of sunspot maximum and minimum, if any systematic variations do in fact exist, must be very small, and the effect of a variation of the intensity of solar radiation upon terrestrial atmospheric processes is likely to be complex.

[1] "Tropical Cyclones of the Pacific." By S. S. Visher. Bernice P. Bishop Museum. Bulletin 20, Honolulu, Hawaii. Published by the Museum, 1925.

[2] "Hurricanes and Tropical Revolving Storms." By Mrs. E. V. Newnham, Geophysical Memoir No. 19, Meteorological Office, 1922.

Another negative or almost negative result of some practical importance relates to the varying degrees of storminess experienced in different years in the Far East. Visher has studied the question as to whether unusual storminess in the early part of a storm season is an index to the probable storminess of the remaining part of that season, and finds that the storminess of June is little or no index, whereas that of July may be of some value. There seems, in general, to be some slight positive correlation between the number of cyclones in one month and the number in the remaining months of the season. This applies to the Far East as a whole, and not to one particular district. It should be noted, however, that variations in the completeness of the information about the number of storms that occur each year would give rise to a spurious positive correlation.

There are many other items of interest in this work which cannot be discussed here, among them a section on the effect of cyclones on the dispersal of life from island to island in the Pacific. The bibliography is very extensive, containing 209 references to other works and articles, and to interviews with other meteorologists.

University and Educational Intelligence.

Edinburgh.—We have already announced the gift to the University by the International Education Board of the Rockefeller Foundation of a sum of £74,000 for the purpose of assisting towards the establishment of a new Department of Zoology. Of this sum, £38,000 is set aside towards the cost of building, £10,000 is for equipment, and £26,000 for endowment. The University already had available from the gift of the late Dr. Laurence Pullar and from the Carnegie Trust a sum of £41,000 towards the cost of the building. The work will be proceeded with at once, and plans will be prepared by Sir Robert Lorimer in consultation with Prof. J. H. Ashworth. The new Department will be at the King's Buildings on the south side of the city, adjacent to the Departments of Chemistry and Geology.

London.—The Laboratory of Civil and Mechanical Engineering at University College is to be named "The Cowdray Laboratory of Civil and Mechanical Engineering," in recognition of Lord Cowdray's generous gifts, amounting to £20,000, to the Faculty of Engineering at the College.

The title of reader in geology in the University has been conferred on Mr. George McDonald Davies, in respect of the post held by him at Birkbeck College. Mr. Davies studied at Birkbeck College. From 1908 until 1920 he was assistant, and latterly senior assistant, in the Mineral Laboratory of the Imperial Institute, and from 1906–20 he held part-time posts at Birkbeck College. Since 1920 he has been head of the Department of Geology at Birkbeck College. His published work includes "Elementary Crystallography" (with Dr. J. W. Evans, 1924), "Tin Ores" (1919), and numerous papers in geological journals.

The following degrees have been conferred:—D.Sc. in botany on Miss Nesta Ferguson (King's College and Royal Holloway College) for a thesis entitled "The Aloineæ—a Cytological Study, with especial reference to the Form and Size of Chromosomes"; D.Sc. in chemistry on Mr. J. W. Cook (University College and the Sir John Cass Technical Institute) for a thesis entitled "The Reactivity of *meso*-substituted Anthracenes"; on Mr. S. B. Dutt (Imperial College (Royal College of Science)), for a thesis entitled "(1) A Theory of Colour on the Basis of Molecular Strain. The Effect of Chromophoric Superposition; (2) Ring-chain Tautomerism, Parts I. and II."; and on Mr. W. G. Shilling (East London College), for a thesis entitled "The Temperature Coefficient of the Molecular Heats of Gases"; D.Sc. in statistics on Mr. Kazutaro Yasukawa (University College), for a thesis entitled "Contributions to the Mathematical Theory of Statistics." D.Sc. (*Economics*) on Miss M. C. Buer (London School of Economics), for a thesis entitled "Health, Wealth and Population in the Early Days of the Industrial Revolution"; D.Sc. (*Engineering*) on Mr. W. D. Dye, for a theses entitled "(1) The Piezo-Electric Quartz Resonator and its Equivalent Electric Circuit; (2) A Self-contained Harmonic Wavemeter," and other papers.

A special course of seven lectures on modern developments in regard to fuel is to be delivered at the Sir John Cass Technical Institute, Jewry Street, Aldgate, London, E.C.3, on Mondays at 6 P.M., beginning on Feb. 7. The lecturers include Mr. F. S. Sinnatt on low temperature carbonisation and Prof. J. S. S. Brame on liquid fuel.

The Ellen Richards Research Prize of the value of 2000 dollars is being offered for award in 1928 "to a woman of any nation on the basis of distinguished scientific research." In countries where there is a national federation of university women this federation may appoint a committee of experts to nominate candidates. Where there is no such federation, nominations may be made by individual women holding university positions. Federations may each nominate three candidates, individuals one. Nominations must be in the hands of the committee before Jan. 15, 1928. Applications for information, circulars, or nomination forms should be sent to the secretary, Mrs. Samuel F. Clarke, Williamstown, Mass., U.S.A.

The Free Place Scholarships Examination, 1926, in the County of Kent, formed the subject of a special investigation conducted, at the request of the Education Committee, by Mr. Andrew Bell. The results of the investigation have been published in a 55-page pamphlet obtainable from the Director of Education, Springfield, Maidstone (price 1*s.* post free). The examination, which is, in Kent, controlled in each secondary school district by the school headmaster, includes—in addition to a written examination, consisting of English, arithmetic, and intelligence test, for which the maximum total marks assignable are 250—an oral test carrying, as a maximum, 100 marks. The Kent County Association of Teachers put forward as one of a series of recommendations, which led to the demand for a special inquiry, a proposal that the oral part of the examination should carry as many marks as the written examination, and one of the objects of Mr. Bell's inquiry was to determine whether this proposal should be adopted. The chapter of the report dealing with this question is of special interest in view of its bearing on the pronouncements of the Board of Education Consultative Committee in paragraph 80 of its report on psychological tests of educable capacity, wherein emphasis is very strongly laid on the value of oral interviews as a means of discovering latent ability and promise. Mr. Bell's conclusion is that in the present state of our knowledge regarding the technique of the interview, it is undesirable that the marks for the oral examination (which each headmaster has full liberty to conduct according to his own ideas) should be increased.

Calendar of Discovery and Invention.

February 6, 1877.—Davy was the first to produce a light by means of electricity, and to him we owe the term 'arc' light. His experiments were made in 1808 with a battery of 2000 cells. Fifty years later practical experiments were made with the arc light fed from magneto-electric machines. With the invention of the dynamo—especially of that of Gramme—further developments took place. Among notable inventions was that of Paul Jablochkoff, who on Feb. 6, 1877, took out the British patent for the so-called 'Jablochkoff candles,' consisting of two parallel strips of carbon separated by kaolin. These lights were installed in the Place de l'Opéra, Paris, and on the Thames Embankment, and with them begins the history of street lighting by electricity.

February 7, 1817.—The great coal gas industry of to-day had its birth in England and France. Gas lighting in America owed much to the artist Rembrandt Peale, who founded Peale's Museum in Baltimore, where he exhibited his pictures and gave lectures. Through his efforts Baltimore was the first American city to adopt gas, the streets being lit for the first time on Feb. 7, 1817. Boston was lighted by gas in 1821 and New York in 1823, but there was considerable opposition to the innovation, and so important a city as Philadelphia had no public gas lighting until 1841.

February 8, 1841.—In 1802, Thomas Wedgwood produced evanescent outlines of shadows on paper moistened with a solution of silver nitrate, but the first photographs of practical value resulted from the work of Daguerre and Niepce. Daguerre's process was described by Arago in January 1839, and in the same month Fox Talbot described his own discovery of photogenic drawing. Two years later, on Feb. 8, 1841, Talbot patented his 'Calotype' or 'Talbotype,' which laid the foundation of modern photography and led to his being called the 'father of photography.'

February 9, 1832.—In the 'twenties and 'thirties of last century a number of steam road-carriages were built and plied for hire. One of the inventors was William Church, whose patent, taken out on Feb. 9, 1832, included a vertical boiler and wheels with elastic rims and spokes. The efforts of Church and his contemporaries Hancock, Gurney and others were, however, rendered futile by the Road Locomotive Act of 1836, which imposed so high a tax on such vehicles that they could not be made to pay.

February 10, 1906.—A modern battleship is an epitome of the application of scientific discovery and mechanical invention, there being few branches of science or engineering which are not utilised in her design, construction, equipment, or maintenance. No battleship ever created more interest than H.M.S. *Dreadnought*, which was launched on Feb. 10, 1906. Designed by Sir Philip Watts, the vessel was 490 feet long, 17,900 tons displacement, mounted ten 12-inch guns, and cost £1,783,883. It was also the first battleship in the world to be driven by Parsons steam turbines, the adoption of which saved 1000 tons in weight and £100,000 in cost.

February 11, 1853.—Through Bence Jones, who had heard of his work in Berlin, Tyndall on Feb. 11, 1853, delivered his first lecture at the Royal Institution, the subject being "On the Influence of Material Aggregation upon the Manifestations of Force." The lecture, which dealt mainly with magnetism, made Tyndall famous as a lecturer, and four months later he was elected professor of natural philosophy, an appointment he held with distinction for thirty-four years.

E. C. S.

Societies and Academies.

London.

Royal Society, Jan. 27.—**S. A. Asdell and F. H. A. Marshall**: The effect of the ovarian hormone in producing pro-œstrous development in the dog and rabbit. Injections of follicular extract obtained from solution in alcohol produce typical pro-œstrous changes in the uterus of the bitch and of the rabbit during the ancœstrous period (that is, at a time when the uterus is normally quiescent). There was also a growth of the vaginal epithelium, followed by a breaking down of the cornified cells. No definite œstrus was produced, so that in the actual production of œstrus a further factor may be involved.

S. Dickinson: Experiments on the physiology and genetics of the smut fungi: hyphal fusion. In investigating the cytology of the covered smuts of oats and barley in pure culture, the fusion, both within and across the species investigated, between the mycelia of different 'gender' derived from single sporidial isolations, was observed. The fusion-hypha is binucleate, and there is nothing suggesting nuclear fusion. The binucleate fusion-hypha gives rise to uninucleate hyphæ, which are of different gender, these being produced at different ends of the fusion-hypha.

J. W. H. Harrison: Experiments on the egg-laying instincts of the sawfly *Pontania salicis* Christ. and their bearing on the inheritance of acquired characters; with some remarks on a new principle in evolution. This gall-making sawfly possesses local races, each with its own special species of Salix as its food-plant. Direct experiment proved that the instinct to oviposit on such special species was inherited. By compelling a *Salix Andersoniana* race of *P. salicis* to lay its eggs on the hybrid willow *Salix purpurea* × *S. viminalis* over a period of years, the habit of choosing that hybrid as food-plant was developed and germinally fixed. This was proved by experimental attempts to throw it back once more on *Salix Andersoniana*. This is a case of the inheritance of acquired characters. Coupling these results with those on the induction of melanism in the Lepidoptera by chemical means, a new principle of evolution on the basis of direct chemical influences on the germ-plasm, whether in the form of the compulsory taking of new food-plants, changed soil conditions, or otherwise, is developed.

L. A. Harvey: The history of the cytoplasmic inclusions of the egg of *Ciona intestinalis* (L.) during oogenesis and fertilisation. Mitochondria are present as chromophobe vesicles with acidophil auræ in the youngest oocytes. They increase in number enormously, and practically all except those in the narrow peripheral layer swell to form yolk. After extrusion of test-cells the remaining mitochondria become granular and uniformly acidophil. The peripheral layer forms a deep cup, which becomes shallower and thicker at the time of fertilisation. The Golgi apparatus passes from primary diffuse to complex, and then to secondary diffuse stage. It consists always of small argentophil vesicles and irregular masses. It is suggested that the 'yolk nucleus' is secreted by the Golgi apparatus very early in oogenesis. It fragments and becomes dissolved in the cytoplasm. The test-cells pour lipoid materials into the egg during yolk formation. The cytoplasm passes from primary oxyphily to basophily and then to secondary oxyphily. These changes are correlated with changes in the Golgi apparatus, as described by Hirschler. The germinal vesicle bursts and the reconstituted nucleus reaches the metaphase of the first maturation division usually before the egg leaves the ovary.

E. Ponder: The measurement of percentage hæmolysis (ii). Two methods for investigating the percentage hæmolysis curves are described; the first, a modification of the radiometer method published in 1924, and the second, using the resistance of selenium as a measure of the light passing through the cell suspension. The form of the curves, for systems in which the lysin is acting alone, can be exactly explained by the assumption that a monomolecular reaction proceeds among a population the resistances of which are distributed according to a frequency curve, usually of Pearson's Type II. The lysins dealt with are saponin and sodium taurocholate. The effect of the accelerators and inhibitors is to alter the resistance of the population to the lysin, the alteration of resistance being described by an expression containing the single resistance constant *R*.

Physical Society, Dec. 10.—**Albert Campbell**: A capacitance bridge of wide range and a new inductometer. A bridge is described by which quick measurements can be made of capacitances covering a range of from 1 $\mu\mu$F up to 30 μF, the power factor also being indicated. The unknown capacitance *C* is put in parallel with a resistance *P*, and the effective self-inductance of the combination, which is approximately equal to $-P^2C$, is read on a mutual inductometer forming part of the bridge. By giving *P* a series of suitable values, scale multipliers prpviding for a very wide range of capacitance are obtained. The inductometer has a circular scale extending to about 260°, the percentage accuracy of reading being almost constant over the greater part of the range. A small rheostat allows the power loss in the condenser to be balanced, and enables the power factor to be deduced.—**Frank Wenner**: A principle governing the distribution of current in systems of linear conductors. The principle applies to systems of linear conductors in which the currents are proportional to the impressed electromotove forces; the electromotive forces may be any function of time, and may be distributed in any manner throughout the system; and the branches may contain resistance, inductance, capacitance or any two or all of these in series, may be so arranged as to move with respect to a permanent magnet, thus developing counter electromotive forces, and may be connected by contacts or mutual inductances or both of these. For such a system of conductors the current in any branch is that which would result if all impressed electromotive forces were replaced by a single impressed electromotive force, located in the particular branch and equal to the drop in potential which originally would have appeared across the break had this branch been opened. While this principle is a logical consequence of well-known laws, it has been very little used. It may be used to advantage in practically all cases in which the conductors form a series-parallel combination or a network which may be changed to a series-parallel combination by opening the branch in which it is desired to determine the current.

PARIS.

Academy of Sciences, Dec. 27.—**H. Deslandres**: The law of distribution of magnetic storms and of their elements. Consequences as regards the constitution of the sun. The notes on this subject published during 1926 are amplified and the general conclusions confirmed, mainly from an analysis of the magnetic observations made at Greenwich.—**L. de Launay**: Some geological applications of transmutation [of elements]. Examples are given of a certain number of constant ratios between two metals associated in the same deposit: silver and lead, gold and silver, platinum with rhodium, palladium and iridium, cadmium and zinc, cobalt and nickel.—**Paul Vuillemin**: New data on the supplementary folioles of strawberry plants.—**Paul Montel**: The series of meromorphic functions.—**R. Wavre**: Iteration by means of a symmetrical and singular nucleus of Fredholm.—**Kolmogoreff**: A divergent Fourier-Lebesque series.—**Swyngedauw**: The angular slip of pulleys and the slip of the driving and driven fibres of the strap.—**Maurice Girault**: A very general construction of the profiles of wings by conformal transformation of a circle.—**A. Couder, A. Danjon, and A. Dufay**: The astronomical quality of the sky of Haute-Provence. Details of studies in this region with the view of placing a large telescope there. The meterological data available suggest that this region should be a very favourable one for astronomical observations. This has been confirmed by direct telescopic work with four instruments.—**Th. Vautier**: Forms and deformations of explosive waves.—**C. Raveau**: The principle of Carnot and the principle of Clausius; various forms of enunciation.—**Georges Déjardin**: The spark spectrum of mercury in the extreme ultra-violet. Measurements of wave-lengths of the three spectra are given up to the limit of the Schumann region.—**Herbert Brennen**: The absorption of β-rays by matter.—**Léon W. Collet and Robert Perret**: Complements on the geology of the circus of Sales (Chaîne des Fis, Haute-Savoie).—**Louis Dangéard**: Current glaucon deposits in the neritic zone.—**Paul Bertrand**: The Mixoneura zone of the upper Westphalian.—**E. de Wildeman**: The yecco, a plant containing caffeine, originating in Colombia.—**A. Hée**: The variations of the respiratory intensity of *Sterigmatocystis nigra* in the course of development.—**G. Mouriquand and A. Leulier**: Does adrenaline exist in the completely free state in fresh suprarenal capsules? The experiments described appear to show that in the fresh suprarenal capsule (guinea-pig) the adrenaline behaves as though it were partly in combination.—**Paul Wintrebert**: Clearing up the eggs of the skate for the continuous observation of the development *in vivo*.—**Y. Manouelian and J. Viala**: Whence comes the virulence of the saliva in rabid animals?—**René Leriche and R. Fontaine**: Some new facts bearing on current theories of vasomotor action.—**A. Sartory, R. Sartory, and J. Meyer**: The formation of the perithecium in *Aspergillus fumigatus* under the influence of radium.—**Edm. Sergent, A. Donatien, L. Parrot, F. Lestoquard, and E. Plantureux**: The virulence of the blood in South African theilerosis (*Theileria parva*).

BRUSSELS.

Royal Belgian Academy, Jan. 9, 1926.—**George Homès**: Stable equilibrium in physico-chemical systems.—**Seligmann and Maury**: The geodesic work of the military cartographic institute.—**Delporte**: Minor planets discovered at the Royal Observatory of Belgium, at Uccle. Two new planets have been discovered since January 1924, when a Zeiss astrograph was installed. The elements of one of these (1925 VD) are given.

Feb. 6.—**A. Gravis**: Contribution to the anatomical study of the shortening of roots.—**A. Demoulin**: The method of the mobile bi-rectangular trihedron and some of its applications.—**Th. De Donder and G. Van Lerberghe**: The electromotive force of irreversible hydro-electric cells.—**R. Moens**: A new method of obtaining sustained electrical oscillations.—**G. Chavanne**: An inactive 1·3 dimethylcyclopentane.—**Maurice Robert**: The geology of the Katanga.—**Du Buisson**: Observations on the tracheal ventilation of insects.—**N. Saltykow**: The application of integrable elements to the integration of differential equations.

Mar. 6.—**Th. De Donder** and **G. Van Lerberghe**: The maximum yield of the chemical reactions of gaseous systems.—**J. Vincent**: The theory of cyclones and anticyclones. An adverse criticism of the theory of V. Bjerknes.—**Maurice Van Rysselberge**: The preparation and study of some 1·2 dimethylcyclopentane compounds.—**G. Balasse**: Study of the luminescence of potassium vapour in the electrodeless discharge.

ROME.

Royal Academy of the Lincei, Nov. 21.—**G. Scorza**: A lemma on the prolongation in the complex body of certain real algebraics.—**G. Armellini**: The variation of the eccentricity in the problem of two bodies of variable masses.—**Q. Majorana**: A residual thermal phenomenon. When heated to high temperatures and then allowed to cool to the ordinary temperature, lead, iron, and copper exhibit rises in temperature incompatible with the known laws of the progressive cooling of bodies.—**F. Zambonini** and **A. Stolfi**: Double sulphates of rare earth and alkali metals. Investigation of a portion of the system $La_2(SO_4)_3 : (NH_4)_2SO_4 : H_2O$ at 25° indicates the formation of the double compounds, 1 : 1 : 2, 1 : 3 : 0, 1 : 5 : 0, and 1 : 6 : 0.—**G. Krall**: The infinitesimal deformation of the field of integration in Fredholm's equations.—**E. Bompiani**: Point and contact transformations in a plane.—**B. Segre**: A generalisation of Koenigs' transformation.—**A. Masotti**: Uniform translation of a round cylinder in a channel with plane parallel sides; second approximation.—**G. de Mottoni**: Control experiments for a new interferometric method for the measurement of microscopic and ultra-microscopic objects by means of diffraction gratings. The percentage error of measurements made by the method recently described has the mean value 3·2 and the maximum value 5·0 per cent.—**E. Fermi** and **E. Persico**: The principle of adiabatics and the notion of kinetic energy in the new undulatory mechanics.—**D. Bigiavi**: Reactions of nitroxyl with aromatic nitro-derivatives and with azoxy-compounds. When an aromatic nitro-compound reacts with nitroxyl, obtained as the sodium derivative together with sodium nitrite when a solution of the sodium salt of nitrohydroxylamine is heated, the nitroxyl is oxidised to sodium nitrite by the nitro-compound, which is transformed into nitroso-compound; the latter does not separate, but immediately reacts with the nitroxyl to give the nitrosoarylhydroxylamine. Azoxy-compounds react similarly with nitroxyl, azoxybenzene, for example, yielding azobenzene and the sodium salt, $C_6H_5 \cdot N : N(C_6H_5) : NONa$.—**F. De Carli**: Additive compounds of sulphur dioxide and aromatic hydrocarbons. Investigation of the diagrams of crystallisation shows that sulphur dioxide forms with toluene the compounds $C_6H_5 \cdot CH_3, 2SO_2$ and $C_6H_5 \cdot CH_3, 3SO_2$, with mesitylene the compound $C_6H_3(CH_3)_3, SO_2$, and with pseudocumene the compound $C_6H_3(CH_3)_3, SO_2$.—**R. Fabiani**: Remains of an eruptive apparatus of Jurassic age found in Sicily.—**F. Rodolico**: Crystallographic investigations on certain hetero-poly-compounds.—**V. Ronchi**: The optical function of the lachrymal liquid.

SYDNEY.

Royal Society of New South Wales, Nov. 3.—The late **J. H. Maiden** and **W. F. Blakely**: Description of fifteen new acacias, and notes on several other species. Of the new species described, eleven are indigenous to New South Wales, two to Victoria, and two to South Australia; twelve belong to series Uninerves, and one each to series Plurinerves, Juliflorae (Stenophyllae) and Bipinnatae (Botryocephala).—**G. J. Burrows**: The solution volume of a solute in liquid mixtures. When a solute is dissolved in a mixture of water with an alcohol or acetone, the contraction that takes place is smaller than that resulting from the solution of the same solute in either of the separate liquids. This result would indicate that there is some relationship between the compressibility of a liquid and the apparent solution volume of a solute in that liquid. By considering the actual contractions that take place when a liquid solute is dissolved in these liquids, however, it is found that the relationship is not quantitative, and it is concluded that volume changes in these cases cannot be reconciled with any simple mechanical theory of closer packing.—**Miss E. M. Bartholomew** and **G. J. Burrows**: The preparation of certain iodo-bismuthites. In an unsuccessful attempt to prepare iodo-bismuthates, the corresponding bismuthites of certain bases such as aniline, dimethyl aniline, phenyldimethyl arsine, etc., were isolated. These are all crystalline compounds which can be recrystallised from concentrated hydrochloric acid without change. They may all be regarded as derivates of bismuthous iodide. The anilinium, pyridinium, dimethyl anilinium, and *p*-toluidinium salts are all derivatives of hexa-iodo bismuthous acid, $H_3(BiI_6)$, whilst phenyl dimethyl arsonium tetra-iodo bismuthite is a derivative of the acid $H(BiI_4)$.—**G. J. Burrows**: The salinity of the water of the Gulf of Carpentaria. Samples of water collected at various positions in the Gulf of Carpentaria have been analysed for the chlorine content. In all cases the salinity is lower than would be expected if the sea water were not diluted with fresh water. The low salt content can be attributed partly to the discharge of fresh water from rivers such as the Roper or Mitchell. The results, however, also show the effect of dilution of the sea water by water from the artesian basin.—**W. R. Browne**: The geology of the Gosforth district, N.S.W. Part 1, General geology. The strata belong mainly to the Kuttung or upper division of the Carboniferous system, but the basal stage of the division is not revealed. A maximum thickness of about 8000 feet of strata is exposed, consisting mostly of lavas ranging from pyroxene andesite to rhyolite, felsite-tuffs, aqueo-glacial conglomerates, varve-shales and tillite. On top of these, with disconformity or slight overlap, lie the Permo-Carboniferous Lower Marine beds. The main structural feature is an irregular dome, of late Permo-Carboniferous age, which has been heavily faulted. The physiography is bound up with the evolution of the Hunter River and the dissection of the faulted dome.

VIENNA.

Academy of Sciences, Dec. 2.—**A. Smekal**: The optical proof of lacunae in the molecular structure of actual crystals. There are deviations from the ideal lattice structure or pores in the lattice. The evidence is in the internal sensitiveness for wave-lengths which are greater than the resonance wave-lengths of the lattice. Alkali salts can be coloured by radiation with ultra-violet light.—**H. P. Cornelius** and **M. Furlani-Cornelius**: Geological researches in the upper Val Camonica.—**H. P. Cornelius**: Geological researches in the lower Veltlin and at the northern end of Lake Como.—**E. Bersa**: Radio-biological investigations; the question of Rontgen radiation of seedlings. Sinapis, Vicia, and Zea were used. A transitory depression was noted in the rate of growth of roots with later recovery.—**S. Strugger**: The influence of hydrogen ion concentration on the protoplasm of root-hairs in *Hordeum vulgare*. The velocity of the plasma streaming was studied between *p*H 6·80 and *p*H 5·50.—**F. Hölzl**: Organic acids and bases in non-aqueous solution. Combinations of amines with dicarbon and aromatic acids were submitted to conductivity measurements.

Diary of Societies.

SATURDAY, FEBRUARY 5.

ROYAL SOCIETY OF MEDICINE (Otology Section), at 10.30 A.M.—Dr. C. P. Symonds: Cerebral Abscess; Some Points in Diagnosis and Localisation.—Dr. Farquhar Buzzard: The Treatment of Traumatic Facial Paralysis.

ROYAL INSTITUTION OF GREAT BRITAIN, at 3.—W. de la Mare: Craftsmanship in Verse.

INSTITUTION OF AUTOMOBILE ENGINEERS (Western Centre) (at Law Courts, Cardiff), at 6.30.—J. Younger: Maintenance in the United States.

MONDAY, FEBRUARY 7.

BIOCHEMICAL SOCIETY (at Lister Institute), at 3.30.—Exhibits and Demonstrations:—W. T. J. Morgan: Apparatus for Pregl's Methods of Micro-analysis.—T. Lumsden and A. C. Kohn-Speyer: Simplified Method of Tissue Culture.—F. M. Burnet: Bacteriophage Phenomena.—M. Rhodes: National Collection of Type Cultures. Strains employed in Industry.—N. S. Lucas: Apparatus for determining the Coefficient of Absorption of Ultra-violet Rays for Skin.—At 5.—Papers:—C. Dorée and E. C. Barton-Wright: A New Type of Alkali Lignin.—F. Dickens, E. C. Dodds, W. Lawson, and N. F. Maclagan: Observations on the Purification and Properties of Insulin.—P. Eggleton and M. G. Eggleton: The Significance of Phosphoric Acid in Muscular Contraction.—I. S. MacLean and C. G. Daubney: The Lipins of Yeast.—W. T. J. Morgan: Methylated Derivatives of Hexosephosphoric Acids.—Prof. A. Harden: Meyerhof's Theory of Alcoholic Fermentation.—Prof. L. F. Hewitt: Proteins of the Cerebro-spinal Fluid.—M. H. Roscoe: Nitrogen Metabolism Technique for Use with Small Animals.—H. W. Southgate: An Efficient Gas Scrubber.—O. Rosenheim and T. A. Webster: On the Nature of Provitamin D.—J. R. Marrack: The Effect of the Reaction on the Osmotic Pressure of Serum Proteins.

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4.30.—Rev. Dr. G. A. F. Knight: *The Identification of the Pharaohs of the Pentateuch.*

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting.

SOCIETY OF ENGINEERS (at Geological Society), at 5.30.—D. C. Fidler: Presidential Address.

INSTITUTION OF AUTOMOBILE ENGINEERS (Bristol Centre) (at Merchant Venturers' Technical College, Bristol), at 6.45.—A. H. R. Fedden: The Supercharging of Aircraft and Motor Vehicle Engines.

INSTITUTION OF ELECTRICAL ENGINEERS (Informal Meeting), at 7.—R. Grierson and others: Discussion on Some Interesting Features in Modern Installation Work.

SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8.—Dr. T. Slater Price: Photographic Sensitivity.

INSTITUTION OF THE RUBBER INDUSTRY (London and District Section) (at Engineers' Club, Coventry Street), at 8.—H. Turner: Set in Vulcanised Rubber.—H. Standring: Rubber Toys.

ROYAL GEOGRAPHICAL SOCIETY (at Æolian Hall), at 8.30.—J. H. Driberg: The Didinga Mountains.

MEDICAL SOCIETY OF LONDON, at 8.30.—Dr. F. Walshe, Dr. M. Gordon, and Sir Thomas Horder: Discussion on Poliomyelitis.

TUESDAY, February 8.

Royal Institution of Great Britain, at 5.15.—Prof. J. S. Huxley: Problems of Animal Growth and Development (2).

Institution of Petroleum Technologists (at Royal Society of Arts), at 5.30.

Zoological Society of London, at 5.30.—The Secretary: Report on the Additions to the Society's Menagerie during the months of November and December 1926 and January 1927.—W. E. Le Gros Clark: Exhibition of Photographs of a Living Tree-Shrew (*Tupaia minor*).—Major S. S. Flower: Loss of Memory accompanying Metamorphosis in Amphibians.—Dr. H. H. Woollard: The Differentiation of the Retina in the Primates.—Dr. F. P. Stowell: Physical and Chemical Conditions in the Fresh-water Circulation of the Society's Aquarium.—Oldfield Thomas: The Delacour Exploration of French Indo-China—Mammals.—Edith M. Sheppard: Revision of the Family Phreatoicidae (Crustacea) with a Description of Two New Species.—Chi Ping: On the Structures of the Hard Palate of *Felis tigris*.—R. Gurney: Some Australian Fresh-water Entomostraca reared from Dried Mud.

Institute of Marine Engineers, at 6.30.—J. G. Weir: Feed Water Circuits for Marine Installations.

Institution of Electrical Engineers (East Midland Sub-Centre) (at College, Loughborough), at 6.45.—H. V. Field: Applications of the Oscillograph.

Electrical Association for Women (jointly with Association of Teachers in Domestic Subjects) (at E.L.M.A. Lighting Service Bureau, Strand), at 7.—W. H. Bush: Electric Light in the Home and in the School.

Institution of Electrical Engineers (North Midland Centre) (at Hotel Metropole, Leeds), at 7.—Informal Discussion on Electric Heating and Cooking.

Institution of Electrical Engineers (North-Western Centre) (at Engineers' Club, Manchester), at 7.—A. R. Cooper: Electrical Equipment of Track on the Underground Railways of London.

Royal Photographic Society of Great Britain (Kinematograph Group), at 7.

Society of Chemical Industry (Birmingham and Midland Section) (at Birmingham University), at 7.15.—F. Twyman: Metallurgical Spectroscopic Analysis.

Institution of Automobile Engineers (Coventry Centre) (at Broadgate Café, Coventry), at 7.30.—A. H. R. Fedden: The Supercharging of Aircraft and Motor Vehicle Engines.

Society of Chemical Industry (South Wales Section) (at Technical College, Cardiff), at 7.30.—Prof. J. Mangan: Micro-organisms of the Soil.

Institution of Electrical Engineers (Scottish Centre) (at McLellan Galleries, Glasgow), at 7.30.—Prof. W. M. Thornton: What is Electricity? (Faraday Lecture).

North-East Coast Institution of Engineers and Shipbuilders (Middlesbrough Branch) (at Cleveland Scientific and Technical Institution, Middlesbrough), at 7.30.—O. Hurst: Some Notes on Naval Architecture.

Quekett Microscopical Club, at 7.30.—Annual General Meeting.

Pharmaceutical Society, at 8.—W. Wyatt: The Acts of Parliament relating to Stamped Medicine.

Royal Anthropological Institute, at 8.30.—Prof. W. J. Sollas: The Chancelade Skull.

WEDNESDAY, February 9.

Institution of Heating and Ventilating Engineers (at Holborn Restaurant), at 2.30.—J. L. Musgrave: Presidential Address.—Dr. Margaret Fishenden: The Effect of Weather Conditions upon the Heat Requirements of a House.

Royal Society of Medicine (Surgery: Sub-Section of Proctology), at 5.—Dr. H. Spriggs (Medical), Sir Charles Gordon-Watson (Surgical), Dr. B. Shires (Radiological), and others: Discussion on Diverticulitis.

Institution of Electrical Engineers (South Midland Centre) (at Midland Institute, Birmingham), at 7.—Prof. W. M. Thornton: What is Electricity? (Faraday Lecture).

Institution of Welding Engineers (at Milton Hall, Deansgate, Manchester), at 7.—P. L. Roberts: The Welding of Cast Iron.

Royal Society of Arts, at 8.—Dr. E. F. Armstrong: The Romance of the Organic Chemical Industry.

THURSDAY, February 10.

Royal Society, at 4.30.—C. D. Ellis and W. A. Wooster: (*a*) The Photographic Action of β-Rays; (*b*) The Relative Intensities of the Groups in the Magnetic β-Ray Spectra of Radium B and Radium C.—A. Muller: An X-Ray Investigation of Certain Long-Chain Compounds.—*The following and other papers will be read in title only*:—Dr. G. M. B. Dobson and D. N. Harrison: Measurements of Ozone in the Earth's Atmosphere and its Relation to other Geophysical Conditions.—Part II.—L. H. Thomas: On the Capture of Electrons by swiftly moving Electrified Particles.

London Mathematical Society (at Royal Astronomical Society), at 5.—Prof. S. Chapman: Some Problems of Terrestrial Magnetism (Lecture).—*The following papers will be communicated by title only*:—T. W. Chaundy: The Genus of an Algebraic Twisted Curve.—E. Cooper: The Behaviour of Certain Series Associated with Limiting Cases of Elliptic Functions.—P. J. Daniell: A Note on Schrödinger's Wave Mechanics.—Prof. G. H. Hardy, A. E. Ingham, and G. Pólya: Notes on Moduli and Mean Values.—Prof. G. H. Hardy and J. E. Littlewood: Some Problems of 'Partitio Numerorum': VIII. The Number Γ(*k*) in Waring's Problem.—L. J. Mordell: A Tauberian Convergence Condition.

Royal Institution of Great Britain, at 5.15.—Sir William Bragg: Acoustical Problems treated by Lord Rayleigh (2): Echoes.

South London Entomological and Natural History Society, at 7.

Institution of Electrical Engineers (Dundee Sub-Centre) (at University College, Dundee), at 7.30.—D. Solar: Three-Phase Power Measurement.

Institute of Metals (London Local Section) (jointly with Electroplaters' and Depositors' Technical Society) (at 83 Pall Mall), at 7.30.—W. R. Barclay: Nickel Coatings—Methods of Production.

Optical Society (at Imperial College of Science), at 7.30.—T. Smith: Some Uncultivated Optical Fields (Presidential Address).

Chemical Society (at Institution of Mechanical Engineers), at 8.—Prof. E. Cohen: Kamerlingh Onnes Memorial Lecture.

Institution of Mechanical Engineers (Leeds Branch).—Prof. A. L. Mellanby and Prof. W. Kerr: Use and Economy of High Pressures in Steam Plant.

Institution of the Rubber Industry (Manchester Section).—J. Lloyd: Proofing.

FRIDAY, February 11.

Royal Society of Arts (Indian Meeting), at 4.30.—Sir E. Denison Ross: The Arabic History of Gujarat (Sir George Birdwood Memorial Lecture).

Royal Astronomical Society (Annual General Meeting), at 5.—Dr. J. H. Jeans: Address on the Award of the Gold Medal to Prof. Frank Schlesinger.

Malacological Society of London (at Linnean Society), at 6.

North-East Coast Institution of Engineers and Shipbuilders (at Literary and Philosophical Society, Newcastle-upon-Tyne), at 6.—Prof. F. Smith: Psychology as an Aid to Efficiency and Economy in Industry.

Institute of Metals (Swansea Local Section) (at University College, Swansea), at 7.15.—J. S. Caswell: The Design of Annealing Furnaces.

Junior Institution of Engineers, at 7.30.—Prof. K. Neville Moss: The Physiology of Work under High Air Temperature Conditions.

Institute of Metals (Sheffield Local Section) (at Sheffield University), at 7.30.—R. T. Rolfe: Bronze.

Oxford University Junior Scientific Club, at 8.15.—Speaker: F. Mitchell Hedges: Primitive Tribes and Buried Cities in Central America.

Royal Institution of Great Britain, at 9.—Dr. E. Law: Old Hampton Court Palace Revealed.

Institution of Mechanical Engineers (Liverpool Branch, jointly with Liverpool Engineering Society).—Prof. A. L. Mellanby and Prof. W. Kerr: Use and Economy of High Pressures in Steam Plant.

SATURDAY, February 12.

Royal Institution of Great Britain, at 3.—W. de la Mare: 'Atmosphere' in Fiction.

Mining Institute of Scotland (at Edinburgh).

PUBLIC LECTURES.

SATURDAY, February 5.

Horniman Museum (Forest Hill), at 3.30.—V. Gordon Childe: The Aryans, our Linguistic Ancestors.

SUNDAY, February 6.

Guildhouse (Eccleston Square), at 3.30.—Maulvi A. R. Dard: The Soul of Islam.

MONDAY, February 7.

University College, at 5.—Dr. A. S. Parkes: Reproduction. (Succeeding Lectures on February 14, 21, 28, March 7 and 14.)

King's College for Women (Household and Social Science Department), at 5.15.—F. Birrell: The Influence of Women on the Public Taste.

University of Leeds, at 7.—Prof. C. T. R. Wilson: Thunderclouds.

TUESDAY, February 8.

Bedford College for Women, at 5.15.—Prof. E. G. Gardner: Conceptions of the Cosmos according to Dante.

King's College, at 5.30.—C. E. M. Joad: Some Aspects of Vitalism: Vitalism and Emergence.

University College, at 5.30.—Dr. M. Wheeler: The Archæology of Great Britain, its Present and its Future. (Succeeding Lectures on February 15, 22, and March 1.)—At 6.15.—Miss E. Jeffries Davis: Some London Place Names. (Succeeding Lectures on February 15, 22, March 1 and 8.) (This course is a repetition of the one given in November 1926.)

WEDNESDAY, February 9.

University College, at 5.—Dr. E. D. Adrian: The Action of the Sense Organs. (Succeeding Lectures on February 16 and 23.)

THURSDAY, February 10.

King's College, at 5.30.—Prof. F. A. Lindemann: The Mind: Physics.

University College, at 5.30.—Dr. C. Sisson: Americans and American Universities.

Northampton Polytechnic Institute, at 7.—R. Genders: Steel and its Thermal Treatment: Defects in Steel.

Fulham Central Public Library, at 8.—R. Kearton: Wild Nature's Ways.

FRIDAY, February 11.

College of Medicine (Newcastle-upon-Tyne), at 4.45.—Dr. C. Singer: History of Medicine (2).

SATURDAY, February 12.

Horniman Museum (Forest Hill), at 3.30.—Miss M. Edith Durham: Some Old Montenegrin Customs.

SUNDAY, February 13.

Guildhouse (Eccleston Square), at 3.30.—N. C. Sen: Brahmo Somaj.

CONFERENCE.

February 10 to 12.

Conference on Maternity and Child Welfare (under auspices of the Society of Medical Officers of Health) (at Newcastle-upon-Tyne).—Papers on Infant Feeding, the Development of Maternity and Child Welfare Work, and the Prevention of Still-birth.

SATURDAY, FEBRUARY 12, 1927.

How Should an Engineer be Trained?

A VERY interesting discussion followed the paper on the training of engineers given by Sir Theodore Morison on Oct. 29 before the North-East Coast Institution of Engineers and Shipbuilders; and a report of it has now been published by the Institution. Those engaging in the discussion were representative of every branch of the profession, and while on some questions differences of opinion were manifest, there was a number of interesting points on which opinion appeared to be practically unanimous. Among these was the general agreement that all university students of engineering should have at least one year's works experience before beginning their university training, and that during this period evening classes should be taken in mathematics and physics with the view of conserving the habit of study engendered at school.

This plan has been advocated for many years by a number of those engaged in university teaching, and it is of interest to know that such procedure now appears to be so generally approved among practising engineers who have studied the question of engineering training. Its advantages are many. It brings a student to his university course with a realisation of the bearing of its scientific training on his future career, such as, in the majority of cases, increases notably his keenness in the work. It gives him, at the most plastic stage of his life, intimate contact with the working man whom in future years he will probably have to control, while the routine work and drudgery which is usually connected with this first period of training is likely to weed out any one whose real interests are not in engineering, and to give him the opportunity of withdrawing before much time has been wasted.

The discussion would have been important if this were the only point on which it has given a definite lead. The chief difficulty in applying it is that at present scarcely any engineering firm in Great Britain is prepared to take a youth for one year preliminary to his university training. If the North-East Coast Institution can persuade its members to adopt this course, arranging to take the youth back to complete his practical training after his graduation, it will have done a very important piece of work and made a real advance in the training of engineers.

Another point emphasised in the discussion was the somewhat haphazard method adopted by the majority of firms in the shop training of their special apprentices. In this connexion matters have improved during the past fifteen years or so, but even now the number of firms which has arranged for the apprentices carefully graded courses of shop training, and see that this training is adhered to, is almost negligibly small.

The sandwich system, in which a youth spends alternate periods of six months in works and at the university, received some support. It is, however, becoming more generally acknowledged that the value to a young engineer of a university course lies almost as much in the facilities which are afforded him for intercourse with fellow students in his own and especially in other branches of study, and in the general activities of student life, as in the technical training which he receives; and that the necessity for keeping terms different from those of the remainder of the university, which is necessary where the sandwich system is adopted, is, from this point of view, a serious objection to the system.

Another point on which opinion was almost unanimous has reference to the requirements for entry to a university course. It was generally felt that the present matriculation regulations operate adversely in the case of many excellent students whose education prior to a shop apprenticeship has been obtained at an elementary school, and whose later work at evening technical schools has shown them to be excellent engineering material.

While one or two universities have recognised the difficulty and have made special provision for such students, the majority of British universities still insist on the normal matriculation, except indeed for mature candidates, and there is little doubt that this insistence is barring each year from the universities a number of young engineers who would richly repay their training.

As Sir Theodore Morison pointed out, engineering is becoming more and more dependent yearly on scientific developments, and its future in Great Britain will depend largely on the type of mind that can be recruited into the profession, and on the methods adopted in the training of engineers. These methods will be investigated by a committee of the North-East Coast Institution of Engineers and Shipbuilders, as suggested by Sir Theodore. It is now more than fifteen years since engineering education was discussed fully at a conference arranged by the Institution of Civil Engineers, and changing conditions have made desirable the re-examination of its many aspects. The recommendations of the committee set up by the North-East Coast Institution will be awaited, therefore, with much interest.

Archæology in South Africa.

The Stone Age in Rhodesia. By Neville Jones. Pp. xiv + 120 + 22 plates. (London: Oxford University Press, 1926.) 12*s*. 6*d*. net.

MR. NEVILLE JONES has earned our thanks for having brought together the evidence of various stone age cultures as derived from Rhodesia, together with some of the data culled from a wider South African area. He has produced a very readable book which contains some valuable information. The whole problem of the South African stone age cultures is every day becoming more interesting and suggestive; and now that search for relics is being conducted upon more scientific lines, we can see the opening of an archæological chapter of high importance. The author's own researches at Sawmills (South Rhodesia) and at Tiger Kloof and Taungs (Cape Province) are valuable as evidencing culture-levels of lower- and mid-Palæolithic *facies*, which can be clearly distinguished and placed in sequence order. He very rightly urges the paramount necessity of attacking the archæological problems from the viewpoint of geological evidence. The numberless stone implements which may be picked up on the surface can teach us little unless we can identify the geologica horizons to which they originally belonged. The spade alone can provide a clear idea as to the severa cultures which may be distinguished, and thei relative positions in the time-sequence. Mr Jones has worked conscientiously and thoughtfully, and his results help to advance the subject.

The value of the book is somewhat marred by unduly positive statements, which lack the support of evidence. To quote examples, which I hope may be modified in a future edition: On p. 1 (and cf. p. 19), in referring to mid-Palæolithic times, Mr. Jones says, "the core implement was thus gradually superseded by the flake implement and finally disappeared altogether." In actual fact core implements persisted in great abundance al through the Neolithic period, while within the Palæolithic period they form one of the most striking features of the Solutréan culture-phase On p. 23 he says, "In Europe the stone implement, in Palæolithic times at any rate, was invariably made of flint," a statement which is quite untrue, since chert, quartzite, and other materials were frequently employed. On p. 19, in his diagram (adapted from Osborn), he asserts that the "bone industry begins" in Solutréan times Why does he ignore the bone implements so char acteristic of the Aurignacian culture ? On p. 44 he states that "in the Maramba . . . the only large palæoliths found in its bed are of diorite." This is not my own experience, for I have picked up in the bed of this tributary of the Zambezi typical large palæoliths of chalcedony and other materials, in addition to those of diorite. It is rather unduly committal at the present stage of our knowledge to assert (p. 21) that "we know for a fact that South Africa was Aurignacian in culture until the Bantu immigrants introduced the use of iron." So positive a dogma is rather premature and may tend to hamper unbiassed research in a field which is essentially complex.

I find it sometimes difficult to follow the author in his descriptions of stone-working technique and in some of his diagnoses of implement types. The 'tortoise-core' figured on p. 53 appears to be quite aberrant and to lack the main characteristics of this specialised core-type. Mr. Jones remarks (p. 26) that "the Mousterian culture has not yet been demonstrated in Rhodesia," but if the 'tortoise-core' industry is mainly suggestive of that culture, as many maintain, it may interest him to know that I have found on the Zambezi banks excellent examples of the 'Levallois' flakes struck from such prepared cores.

The author's description of the probable process whereby the leaf-shaped blades from the Cape Flats were made can scarcely carry conviction. Has he ever tried to effect the "removal, probably *by pressure* [italics mine], of minute chips over the entire surface" of a large piece of quartzite ? If so, has he ever produced an effect similar to the surface-flaking of this type of implement ? I venture to doubt it. He compares (pp. 56 and 113) the finest of the Cape Flats implements with the best examples of Solutréan technique; but this seems to do scant justice to the marvellous skill exhibited by Solutréan man. Surely no blades in any way comparable with those of Volgu have as yet been found in South Africa, and the Cape Flats examples, for all their high quality, exhibit, to my mind, a far easier technique.

Mr. Jones (p. 12) defines a 'burin' as a 'boring instrument,' but its proper function was engraving, not drilling, and its archæological interest lies in its association with engraved designs. He has adopted the unsatisfactory term '*boucher*' for the '*coup-de-poing*' or 'hand-axe' series of lower palæoliths, and urges that this name "has the special virtue of being non-committal." But surely, quite apart from introducing a scheme of nomenclature by Christian names, which may easily lead to ridicule, the fact of its being non-committal is against its employment. Personally, I have been much exercised to discover exactly what type or types of implements it is intended to include under the term. Prof. Sollas originally applied it to a type of *flake* implement, but the present author and others employ it to designate *core* implements. It would be better to drop the term altogether and adopt a series of more committal and distinctive type-names.

The author does not refer to the discovery in Rhodesia of minute implements of Tardenoisian type, though it is many years since the first example was found in Buluwayo. Tardenoisian types are now being discovered abundantly in South Africa, and are a noteworthy feature of the region.

The illustrations of implements in this book vary much in value. Some (*e.g.* Fig. 39) are quite good; others are so lacking in detail and 'crispness' that they convey little beyond mere outline and nothing as regards technique. The description (p. 54) and the figure referred to (Fig. 13, No. 26) appear to be totally unrelated.

Apart, however, from these and several other points which invite criticism, the book is a welcome one, dealing with problems of ever-increasing interest. The author endeavours to approach his subject without bias, and to treat the evidence as he finds it. The task of correlating the South African stone age cultures with those of Europe is beset with pitfalls, but is none the less attractive on that account.

The author's diagnosis of Bushman art is carefully thought out and is in agreement with the most widely held views. His statement of the case for magic versus 'art for art's sake,' as the primary incentive, would have been greatly reinforced had he brought to bear upon it the evidence afforded by late Palæolithic art in Europe. It is interesting to note that he adopts the theory that the gravels lying along the top of the gorge of the Zambezi, below the Victoria Falls, are the remains of ancient gravels deposited by the Zambezi itself. My own investigations, conducted during three visits to the region (in 1905, 1907, and 1910), led me to adopt this view, which, *pace* Dr. Codrington, has been supported by several very able geologists. The Appendix III. in Mr. Jones's book, detailing the views of Dr. Hrdlička upon this problem, should not be taken too seriously. The very hurried survey conducted by a distinguished physical anthropologist, in company with two American newspaper men and a South African engineer, does not carry conviction, nor does it dispose of the views of such capable geologists as Lamplugh, Zealley, and others. Further, close examination by trained geologists is needed to settle the matter finally. The age of these Zambezi gravels is one of the most important problems awaiting solution.

HENRY BALFOUR.

Chemist and Philosopher.

The Anatomy of Science. By Prof. Gilbert N. Lewis. (Yale University: Mrs. Hepsa Ely Silliman Memorial Lectures.) Pp. x+221. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1926.) 14s. net.

"AS the artist, after painstaking effort, steps back from his easel to view his picture as a whole, so it may not be unprofitable for the scientist to forsake from time to time his own specialty and survey the general trend of science." So writes the author of this volume of Silliman lectures. Not only is such action not unprofitable, but also it is of the highest importance that leading men of science who, like Prof. G. N. Lewis, possess in such high degree wide scientific knowledge, clear philosophic insight, and the power of lucid and interesting expression, should from time to time examine the existing state of science and the directions along which our knowledge of the universe is advancing. The author's purpose in this volume is to present "a kind of contemporaneous cross section showing the inner structure of science," and the book is addressed to those "who are interested not so much in the products of science as in its methods." By all such, these lectures will be given a hearty welcome.

After a short survey of the methods of science, in which perhaps the rather too facile view is expressed that the scientific method is "hardly more than the native method of solving problems," the author proceeds to a discussion of the theory of numbers, space and geometry, time and motion, matter in motion, light and the quantum, probability and entropy, the non-mathematical sciences, and life, body and mind.

In the lecture on space and geometry are discussed the non-Euclidean geometries, more especially Minkowski's geometry of asymptotic rotation, the details of which have been worked out by the author and Prof. E. B. Wilson, and the geometry of shear rotation. According to Minkowski's geometry, all points on the hyperbolic curve are equidistant from the point of intersection of the asymptotes, and any interval marked off on one of these asymptotes is of zero length. To a Euclidean mind such language is nonsense, but, as the author points out, each geometry has its own definitions and postulates just as each game has its own rules; and to the query whether such geometry is true or false, the author replies that the question has no meaning in science. All that one is concerned with, as in the case of all scientific theories, is its usefulness; and the usefulness of the Minkowski geometry is demonstrated by the author in connexion with the new kinematics based on the Einstein theory of relativity—a kinematics which Euclidean geometry is powerless to express.

In discussing light and the quantum, the author introduces his theory of absorption of light and interference, an account of which has already been published in NATURE (117, 236, 1926). In this theory the assumption is made that an atom never emits light except to another atom, and one can no longer regard the one atom as an active agent and the other as a passive recipient. According to this theory, when one arranges an optical apparatus so that interference bands are produced, one not only brings it about that no light is received on the dark band, but also the light which otherwise would have fallen in the region of the dark band is not *emitted*. The author recognises that such an idea, which is really equivalent to saying that we can influence events which are already past, is offensive to our established notions of causality and temporal sequence, but he holds that we need not therefore be deterred from making use of the hypothesis so long as no actual fact of experiment or observation can be brought against it, especially since by its means "certain inconsistencies between prevailing physical ideas and the geometry which so admirably interprets the kinematics of relativity are removed." This view can of course be accepted, but does it not imply that we are here dealing merely with a mathematical device which may later have to be discarded or receive interpretation by a more complete physics?

In the concluding lecture, the author boldly, but apparently with a certain amount of trepidation, attacks the problem of life. While professing ignorance of the meaning of the term 'vitalist,' the author proclaims that "it is indisputable that many of the characteristic properties of living beings are not only far beyond the reach of existing physical science, but are not even suggested by the most remote extrapolation of the laws and theories that we have made to fit the inorganic world." Of the phenomena which have no counterpart in inanimate Nature, one of the most striking is known as the struggle for existence. In concluding his lectures the author says: "The sciences of physics and biology comprise sets of man-made postulates and laws which no more need to be compatible with one another than do the geometries of Euclid and Lobachevski. The science of physics rests upon the postulate of determinism; the science of biology, unless it is to ignore deliberately the phenomena of behaviour, must abandon this postulate and substitute therefor a postulate of choice or freedom."

The book is most refreshing to read, owing to the sense of humour of the author and the clearness with which he expresses his views, and it is also most stimulating and provocative of thought. It suffers, however, from over-condensation. The author confesses that the collection of "simple essays" has been brought "by the publishers to the dimensions of a book only by generous spacing between the lines," and he obviously expects the reader to read rather extensively between these lines. There are, however, very many people, not all of them laymen in the domains of science and philosophy, who are intensely curious concerning the subjects treated in these lectures, but will find it very difficult, if not impossible, to make the necessary interlections. May we not express the hope, therefore, that the author will place the world still more in his debt by giving to it an expansion of this excellent outline of a system of philosophy? Meanwhile, we are grateful for this smaller work.

Alex. Findlay.

Carbohydrate Metabolism and Insulin.

Carbohydrate Metabolism and Insulin. By Prof. J. J. R. Macleod. (Monographs on Physiology.) Pp. xii + 357 + 4 plates. (London: Longmans, Green and Co., Ltd., 1926.) 18*s*. net.

THIS comparatively large volume furnishes an excellent description of carbohydrate metabolism in general. This is only what might be expected from such a well-known author as Prof. Macleod, who has done so much useful work on this subject. To anybody wishing to get a fundamental idea of our present knowledge in this field of metabolism the book can be confidently recommended. Of all the volumes of literature on the difficult and evasive problem of carbohydrate changes in the animal body, the present appears certainly to be the best. It deals with the subject in a clear though fundamental manner, and embraces everything that is known as to the physiology of carbohydrate metabolism.

The book opens with a chapter on the structure of the islets of Langerhans and their cytological characteristics. This is followed by a useful description of the structural changes which the pancreas undergoes under various experimental conditions. The various mechanisms of the different forms of glycosuria are concisely discussed, followed by a complete description of glycogen and the various changes this substance undergoes in the body. Methods for the estimation of blood sugar are mentioned, and the manner of existence of the sugar in the blood is discussed briefly. The author does not accept the view propounded a few years ago to the effect that the sugar in the blood of the healthy animal is not ordinary glucose, but a very reactive modification known as γ-glucose. It is pointed out that the alleged evidence for the occurrence of γ-glucose in the animal organism is exceedingly unsatisfactory, for this substance is so labile and unstable that even if it did occur in the body, it would be almost impossible, with our present methods, to isolate and identify it.

Naturally, a great deal of the volume is devoted to a study of the action of insulin, and while this part of the book is done just as well as the rest of it, it must be admitted that a perusal of Prof. Macleod's critical compilation on this subject leaves the impression that there is yet very much to learn. The hopes held out a few years ago that the advent of insulin would solve many of our hitherto insoluble problems have been almost entirely unfulfilled. In spite of the very large amount of experimental research, both good and bad, carried out on the particular influence of insulin in the utilisation of carbohydrate in the animal body, it is safe to say that as yet but little advance has been made in this difficult field. When we consider that the products of sugar destruction are comparatively simple, and, from the chemical point of view, necessarily limited to a few substances, it is a matter for wonder that, so far, we have failed to trace the various steps through which sugar is broken down to carbon dioxide and water. It is true that some glimmerings of light have now and again appeared within the last few years, but nothing definite has so far transpired.

Insulin has, on the whole, been a disappointment so far as it has afforded any insight into the physiological processes which the body employs. Very many papers have appeared, and are still appearing, which deal with the manner in which insulin acts, but the many controversies and difficulties which have arisen seem to have been solved by the work of Dale and his collaborators, who state that insulin acts by changing some of the sugar of the body into glycogen, and by oxidising the rest of it. These authors believe that the disappearance of sugar, after insulin administration, can be accounted for by the sugar destroyed and the glycogen formed.

This means, as was to have been anticipated from the very beginning, that insulin acts when injected just as it does when supplied normally by the pancreas. The problem is, how does insulin act when it is supplied in the natural manner to the healthy individual? That problem still awaits solution, and we know little or nothing at present with regard to it.

From the clinical point of view, it would appear that insulin in several cases produces changes in the diabetic which are not obvious in the normal individual, but it is quite possible that these changes may be dependent on the difficulty of administering the optimum dose when insulin is given artificially. However, the rapidity with which several diabetic patients become abnormally fat when taking insulin, suggests that insulin probably has some direct influence on the formation of fat from sugar in the body.

To anybody interested in this fascinating though difficult subject of carbohydrate metabolism, a perusal of Prof. Macleod's volume will serve to give an exact and well-reasoned view of the present position of this subject. It would appear probable, however, that what is believed to be true to-day will undergo vast modification in the future. The subject, so far, has not yielded to attack, and whatever we write or think, it is certain that we know but little of the real facts. H. MACLEAN.

The Terminology of Electrical Engineering.

British Engineering Standards Association. Publication No. 205, 1926: *British Standard Glossary of Terms used in Electrical Engineering.* Pp. 263. (London: British Engineering Standards Association; Crosby Lockwood and Son, 1926.) 5*s.* net.

PURSUING its work of standardisation, the British Engineering Standards Association has issued a glossary in which the terms in common use in electrical engineering are defined, so as to provide engineers with a uniform nomenclature. With this end in view, the compilers frequently give a list of the synonyms actually in use, indicating their preference by heavy type, and in some instances marking others as 'deprecated.' From this point of view, the sections on composit machines (*i.e.* converters of all types) and transformers, and that part which deals with the exac uses of such terms as 'protected,' 'enclosed,' an 'flame-proof,' will be valuable in giving exac meanings to terms which have not always bee used in the same way by different writers.

As is to be expected in such an undertaking there are cases where the choice will not meet wit general agreement; particularly is it to be hope that the engineering world will not adopt th suggestion of calling the extreme range of a wav the 'double amplitude,' whilst it will be interestin to see if the terms 'active current' (the tabulate alternatives being active component, energy component, power component, and in-phase componen of the current) and 'reactive current' (for th other component) succeed in ousting their rivals We also note that the distinction between a oscillating and an alternating current is made t depend on whether the frequency is or is no dependent solely on the constants of the syste in which it flows.

As to the definitions themselves, they are for th most part adequate for their purpose, but it i doubtful whether much good is done by defining for example, the blade of a switch, and the contac jaws, in a reciprocal manner, except in cases wher it is desired to indicate that one of a number o alternatives is preferred. It is, however, in th general section that the weakest definitions occur Apart from the vexed 4π question, we find separat definitions of quantity and of charge, and each o them is logically unsatisfactory, although no doub adequate for the restricted purpose of this glossary Quantity is given as the product of current an time, whilst current is earlier defined as quantit per second. Charge is stated to be 'an excess or deficiency of electrons on a body, causing electric effect in the neighbourhood'; but definition 1102 gives th meaning of 'electron' as the fundamental unit o negative electricity. On this subject of electrica units it seems rather a pity that the term selecte for the B.T.U. should make the definition commence 'Unit of Electricity: a Unit of Electrica Energy.' It is also to be regretted that whil the numerical value of the electronic charge i quoted, and values given for the B.Th.U. in joules other useful figures, such as the ratio of the tru to the international volt, and the E.M.F. of th Clark and cadmium cells, are omitted. On would also have liked more information on th International Candle, which is here stated simpl to be a unit of luminous intensity, arrived at b common agreement between certain specified institutions. It is also to be regretted that the term 'thermo-electric effect' has been restricted to one particular effect.

Lest this catalogue of blemishes (impossible to avoid in reviewing a work in the form of a glossary) should convey a wrong impression, it must be pointed out that they concern but a small fraction of the total number of entries, most of which are very clear, and should materially assist in attaining the ideal of one definite term for each concept requiring expression. The book is excellently produced, is divided into sections, and provided with a very complete alphabetical index, in which all the terms are indexed, whether or not they are 'deprecated' in the body of the work. Misprints are very few, the following list including all that have been noted: in definition 1510 the second 'per sec.' is omitted, and in No. 1901 the figure 3·68 should be 36·8. In the index, under 'charge' the figures 1210 and 1310 should be 1201 and 1301.

J. H. A.

The People of China.

Anthropology of Eastern China and Kwangtung Province. By S. M. Shirokogoroff. Pp. vi + 162. (Shanghai: Royal Asiatic Society, North China Branch, 1925.) 5 dollars.

AN account has already been given in NATURE (Dec. 12, 1925, p. 855) of the anthropological inquiries now being conducted in China by Dr. Shirokogoroff and described by him in a series of reports. The volume already discussed dealt with the populations of the provinces of Kiangsu and Chekiang. The present work gives further information relating to the living people of these provinces as well as of Kwangtung, and in fact of the eastern part of China. It is essentially a statistical investigation, and is free from speculations as to the assumed influence of the endocrine glands in causing racial differentiation, to which particular reference was made in the previous review.

The real value of the present, like the former, report is the new data submitted by Dr. Shirokogoroff, who seems to have cast his net widely in the process of collecting both measurements of living people and comparisons from the literature of anthropology, especially many references to eastern Asia not readily accessible to students in western Europe.

By the analysis of series of measurements, the attempt is made to define different types and to estimate their relative representation in the populations of the various provinces. The commonest of these types in the northern provinces and in Manchuria is characterised by high stature (1·75 m.), a low cephalic index, and a high nasal index. In the provinces of Kiangsu and Kwangtung this type is said to be absent. It is rare in Anhwei and Chekiang. In central China (Honan) it is common, and in Chili and Shantung it is the usual and characteristic type. His second type is distinguished by a smaller stature (1·60 m.), a high cephalic index, and very high nasal index. Its geographical distribution is very wide, being the dominant type in eastern China and Korea (possibly also in Japan). It is also common among the Manchurians and the Northern Tungus.

If these results should be confirmed by further studies, they will necessitate considerable re-orientation of current views on the distribution of Mongolian types. So far, however, the conclusions are tentative. They have met with severe criticism, especially (according to this memoir) from Prof. Tschepourkowsky of the University of Vladivostok, "one of the leading sovietic anthropologists," who has asserted that types claimed to have been identified by Dr. Shirokogoroff in northern China "are a mere phantasy."

G. ELLIOT SMITH.

Our Bookshelf.

Getting out the Coal: Stripping, Underground Mining, Loading Machines, Roof Support. Compiled by Frank H. Kneeland. (Practical Coal Production, Vol. 2.) Pp. vii + 403. (New York: McGraw-Hill Book Co., Inc.; London: McGraw-Hill Publishing Co., Ltd., 1926.) 15*s*. net.

THE present volume is a continuation of a volume on preliminaries of coal mining, etc., compiled and published in the same way as the present volume, which was reviewed in these columns in June last year. Practically the same criticism that was applied to the previous volume holds good for the one now before us. It deals almost entirely with American methods and American practice, though a few pages are devoted here and there to English methods by way of directing the attention of American engineers to them, though it cannot be said that the British illustrations which have been suggested are at all typical of the best British practice.

The work is divided into four chapters: Stripping or surface mining; underground methods of mining, constituting the bulk of the book, so that more than half the text is contained in this one chapter; loading, loading machines, and conveyors; timbering and roof support. The first chapter is naturally of no use to the British colliery engineer, especially as the greater part of it is devoted to the stripping of anthracite. As regards the second chapter, it is of no use to engineers in England, and probably of but little use even to American engineers, because the most recent methods are not discussed. The chapter on loading machines and conveyors is decidedly disappointing; the compiler appears to have got his information on the subject of loaders mainly from the builders of the machines, rather than from their users, and gives the impression of not having been in touch with their practical use underground. He entirely ignores the existence of the gate-end loader which is making considerable headway in Great Britain, and omits from the discussion some of the modern American cutting and loading machines which are being tried out in West Virginia.

The last chapter on timbering, etc., again is unsatisfactory. The compiler has attempted to work out certain formulæ for determining the size of timbers to be employed; he gives one of these on p. 307, and is apparently unaware of the fact that he is repeating the same formula only slightly altered in form and in the letters used in designation on p. 331. His confidence in his own formulæ is best expressed by the statement that he solves a particular example, and shows that according to his formula "a 4⅛-in. stick will support the load"; he goes on to say, however, that "in this case it would be advisable to use a larger stick, say, 8 in. diameter."

Geologie von Europa. Von Prof. Dr. Serge von Bubnoff. (Geologie der Erde.) Band 1: *Einführung, Osteuropa, Baltischer Schild.* Pp. viii + 322 + 8 Tafeln. (Berlin: Gebrüder Borntraeger, 1926.) 22·50 gold marks.

The present volume forms the second instalment of the "Geologie der Erde," vol. 1 of Prof. E. Krenkel's "Geologie Afrikas" having been published about a year ago. The whole project is a decidedly ambitious one, for the aim is to give a comprehensive and correlative account, from the structural as well as from the stratigraphical point of view, of the geology of the earth, each continent being dealt with separately.

Prof. von Bubnoff has been faced with a task more formidable than that of any of the other contributors, so complicated is the structure of the continent of Europe, and so extensive the literature. He sets out in the first place to determine from palæogeographical considerations what are the fundamental structural divisions of the whole area, and shows how, with certain modifications due chiefly to the great mountain-building movements, the character of each region has tended to remain constant throughout geological history. He then discusses the variations in gravity over the continent, the general distribution of ore-deposits, and the present-day morphology.

The rest of the present volume is devoted to a detailed account of eastern Europe, the development of which is shown to have been independent of that of western Europe since Palæozoic times. The Ural Mountains, the Posthumous Uralides, the Russian Platform, the Baltic Shield, and the Podolian Massif are dealt with in turn, and an account given of the stratigraphy, the orogenesis the ore-deposits, and the morphology of eac region, together with references to the more important literature. As might be expected, th text makes rather solid reading, but, fortunately it is well illustrated by explanatory maps an sections. The appearance of the remaining tw volumes, which are to deal with western and wit Mediterranean Europe, will be awaited wit interest, since the complete treatise will undoubtedl fill a gap in geological literature and be of considerable use as a work of reference.

Die Ökologie der blattminierenden Insektenlarven Von Dr. Martin Hering. (Zoologische Bausteine Ausschnitte aus dem Gesamtgebiet der Zoologie Band 1, Heft 2.) Pp. iv + 253 + 2 Tafeln. (Berlin Gebrüder Borntraeger, 1926.) 18 gold marks.

Only a few months ago we had the opportunit of noticing Dr. Hering's "Biologie der Schmetterlinge," and it is seldom that an author is able t produce two works of evident scientific meri within a period of less than a year. The treatis before us is the result of the study of the specialise subject of leaf-mining insect larvæ.

A great deal of the information that lies scattere through the pages of numerous periodicals ha been critically examined and gathered together i producing this book. At the same time, Dr. Herin has incorporated much of his own studies, and ha imparted greater exactness and a more scientifi viewpoint, in what has hitherto remained an ill defined branch of entomology. In order to achiev his object he has coined a special terminolog which differentiates the various characteristi features of miners. As the names which he adopt are short and convenient, it is possible that the may find acceptance.

The book is divided into sixteen chapters, eac one being devoted to a particular aspect of th subject. Thus, Chap. i. is concerned with th definitions and the general morphology of mines Chap. ii. deals with mines in different parts o plants; Chap. iii. with 'stationary' and 'temporary' miners; and Chap. vii. discusses larva structure in relation to mining habits. Chap. x is concerned with problems relative to the nutritio of miners, and there are chapters dealing wit aquatic mines and on the parasites, inquilines, an symbionts of mining larvæ. The book is wel printed and illustrated; it is provided with a ver complete bibliography, and the price on the whol is reasonable.

A. D. I

Meteorological Office: Air Ministry. British Rainfall, 1925: the Sixty-fifth Annual Volume o the British Rainfall Organization. (M.O. 285. Issued by the authority of the Meteorologica Committee. Pp. xviii + 279. (London: H.M Stationery Office, 1926.) 15*s*. net.

For the year 1925 the rainfall over the Britis Isles was very slightly above the average and ca be taken as normal. In some districts abnormalities occurred; among the most remarkable o these was the exceptionally dry June, which wa absolutely rainless in many localities and one of the driest months on record for the British Isles as a whole. The cold and cheerless summer was the fourth summer in succession of that nature. In spite of the large number of thunderstorms, especially in May and June, there were few days with heavy falls of rain.

A special article is given showing a comparison of the fluctuations experienced at two standard stations—Oxford, fairly central in England, and Glenquoich in the western Highlands of Scotland—and maps are given showing the results of these statistical investigations, considering also their relation to other places in western Europe. A classified list appears of the papers published in "British Rainfall" in the last twenty-five years. A summary is also given of some experiments on the shielding of rain-gauges made at Valencia Observatory in Ireland. The question of over-exposure is discussed as well as insufficient exposure. The effect of wind conditions is considered upon the catches in recording gauges.

Post-Prandial Proceedings of the Cavendish Society. Sixth edition. Pp. 37. (Cambridge: Bowes and Bowes, 1926.) 2*s*. net.

THIS collection of verses began with a few songs written for 'community singing' at the annual dinners of the research students of the Cavendish Laboratory. The first collection was privately printed in 1904, and similar editions with new songs added appeared in 1906, 1907, and 1911. Some of these were of a purely ephemeral interest and were omitted in the first published edition of 1920. The present edition was published in connexion with the dinner held in celebration of the seventieth birthday of Sir J. J. Thomson. Several of the songs are tributes to him, including a "Biographical Sketch," which gives a versified account of his career up to date. The author of this, as of most of the best songs in the volume, shelters himself modestly behind the initials "A. A. R." The 'J. J.' songs reveal the extraordinarily happy personal relations which have always bound the research students to their professor, while the songs in honour of Sir Ernest Rutherford are sufficient evidence that the old tradition is being carried on. The remaining songs deal with important branches of modern physics from the electromagnetic theory to the quantum theory. All old Cavendish students will welcome the appearance of this new edition, which is greatly improved in form, and a much wider public will find it both interesting and entertaining. A. W.

Animals Looking into the Future. By Prof. W. A. Kepner. Pp. xi+197. (New York: The Macmillan Co., 1925.) 7*s*. 6*d*. net.

THE author aims, in this book, to demonstrate that in all animals, from the lowliest protozoa to man, prescience is a marked characteristic, and one that fundamentally distinguishes the organic from the inorganic world. Both mice and men have plans, and from a brief consideration of the habits and organisation of certain colonial and solitary insects, and of the structure and physiology of more lowly animals like Hydra, Microstoma, and even the protozoa, the author seeks to emphasise this point of view. Even plants look into the future. It is true that a distinction is made between the conscious prescience of man and the instinctive prescience of insects or Hydra. The author, however, in his enthusiasm for the text of his sermon, has imparted too anthropomorphic a bias to his presentation. "Therefore, in the formation of nematocysts by the interstitial cells of Hydra we see these living units sacrificing themselves in a prescient manner with reference to the welfare of the individual polyp." This quotation, which gives an idea of the author's thesis, may easily suggest conscious thought to the layman, and it is for the layman that this book is written. It is a little dangerous to attempt the popular exposition of biological phenomena in language which may convey an erroneous interpretation to the lay mind.

Contributions to the Art and Science of Otology. Lectures and Papers by Richard Lake, 1892–1925. Pp. vi + 255. (London: Macmillan and Co., Ltd., 1926.) 15*s*. net.

THIS book consists of a collection of the author's more important contributions to current medical literature extending over a period of thirty-three years. It comprises within the limits of 255 pages fifty separate items, made up of case records, clinical lectures, addresses to medical societies, and articles, more or less controversial, on current otological topics. It is the index of an industrious and intellectually active professional career, which may well be a source of legitimate satisfaction to the author, and of interest to his colleagues and to the students who have received their training at his hands. There is not much in it that is of general scientific value at the present day. So far as the scientific side of his subject is concerned, we may cite some careful observations on tuning-fork tests of hearing in various forms of deafness. The author lays emphasis on common sources of error arising from the personal factor in examiner and examinee. No doubt in the near future our estimate of the value and significance of the various methods of testing hearing will have to be recast in view of the recent introduction of more absolute methods of audiometry.

Biochemie des Menschen und der Tiere seit 1914. Bearbeitet von Dr. Felix Haurowitz. (Wissenschaftliche Forschungsberichte, Naturwissenschaftliche Reihe, Band 12.) Pp. xii + 148. (Dresden und Leipzig: Theodor Steinkopff, 1925.) 7 gold marks.

THIS little volume gives, in a handy form, short reviews of a wide selection of biochemical subjects: each is accompanied by a large number of references to the literature, which appear to have been well selected. The arrangement follows that usual in text-books of biochemistry and physiology. The volume should be of use to those who wish to look up recent work on a specified subject without the necessity of referring to the original papers.

Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of Nature. *No notice is taken of anonymous communications.]*

A Quantum Relation in Large Scale Electric Wave Phenomena.

It is well known that associated with a medium containing free electrons of mass m and charge e there is a definite critical frequency ν_e where $\nu_e^2 = \frac{Ne^2}{\pi m}$. This frequency is characterised by the fact that electric waves of frequency less than ν_e cannot travel through the medium.

The group and phase velocities of waves of greater frequency than ν_e are given by the relations:

$$V_{\text{phase}} = \frac{c}{\sqrt{1 - \frac{\nu_e^2}{\nu^2}}},$$

$$V_{\text{group}} = c\sqrt{1 - \frac{\nu_e^2}{\nu^2}},$$

so that they tend to ∞ and 0 respectively as: $\nu \longrightarrow \nu_e$.

This relation:

$$\nu = \nu_e \text{ or } \frac{Ne^2}{\pi m\nu^2} = 1,$$

which determines the critical frequency of the medium, can be expressed in a way which connects it up with the quantum theory. In a paper in the *Philosophical Magazine* (July 1926, vol. 2, p. 267) I showed how to calculate the ratio $\frac{4\pi h\nu}{\beta^2}$, which is the ratio of the total energy of a quantum (engaged in an encounter with an electron) to the energy per unit volume. This ratio must therefore be of the dimensions of a volume which, for want of a better expression, was called "The Volume Occupied by the Quantum."

The expression which represented this quantity was found to be:

$$\frac{e^2}{\pi\nu^2 m_e} = V \text{ say,}$$

so that the relation giving the critical frequency can be expressed in the simple form $NV = 1$. Since $1/N$ is the average volume occupied by each electron, we may say that the critical frequency occurs when this is such that the 'volume occupied by the quantum' is equal to the average volume occupied by each electron. In order to conform with the ideas of statistical mechanics, of which long-wave propagation appears to be an example, I prefer to consider that $NV = \nu_e^2/\nu^2$ represents the probability of a direct hit of the quantum and electron, or more precisely the fraction of quanta per unit volume which are in collision at any instant with the electrons in that volume. In the case of the critical frequency this probability is unity, and the relations of quantum mechanics gives a justification for the use of this description. For the analysis of the 'Compton scattering' shows that when a direct hit occurs the momentum given to the electron $M = \frac{h\nu}{c}(1 - \cos\theta)$, where θ is angle of scattering; the average of which may be considered to be: $h\nu/c$ the momentum in the wave.

It follows that when the probability of a direct hit is unity all the wave momentum will on the average be given up to the electrons and the wave can travel no farther, this state of affairs resulting in the zero group velocity which occurs at the critical frequency.

In one respect this analysis seems to shatter the picture of a quantum as an objective particle of radiation, for such a picture would inevitably imply that the probability of a direct hit should be jointly proportional to the radiation energy density or density of quanta and the electron density, whereas the foregoing analysis shows this probability to be independent of the density of quanta.

This aspect of the quantum theory has already been pointed out by Eddington in his discussion of Einstein's derivation of Planck's law of radiation ("The Internal Constitution of the Stars," p. 56).

Non-Magnetic Films of Iron, Nickel, and Cobalt.

A year and a half ago one of us (Ingersoll and De Vinney, *Phys. Rev.*, 26, 86, 1925) reported the results of some experiments on films of nickel cathodically sputtered in hydrogen at a pressure of 1 mm. or less. These films as produced were entirely non-magnetic, showing no tractive effects in a strong magnetic field. Upon heating to about 350° C. for a few minutes, however, they become strongly magnetic.

We have since continued this work on nickel and extended it to iron and cobalt, and find that, while it does not seem possible to produce non-magnetic films of these latter metals in hydrogen, they can be made in helium. Argon has also been used as a residual gas with nickel. In all cases heating for a few minutes to 350° or more in a vacuum—or, for that matter, passage through a bunsen flame in air—makes films of these three metals strongly ferro-magnetic.

The crystal structure of these films has been investigated by the X-ray method (iron and tungsten anticathodes). In the original work on nickel the evidence was to the effect that, while the film after heating showed the normal lattice for nickel, as originally produced it was amorphous, giving no clear evidence of crystal structure. In our recent work, however, we find—using an improved technique, whereby the crystal structure is determined without removing the film from the glass—that the film as produced (*i.e.* non-magnetic state) has in general the same crystal structure as after heating but *with a larger lattice spacing*. The distension or swelling may be so much as 20 per cent. In most cases the lattice shown by the film after it has been heated and rendered magnetic is the normal one for the metal: the exceptions may be explained on reasonable grounds.

The basis on which we are seeking to explain these facts is the occlusion by the metal of large amounts of the residual gas, *i.e.* hydrogen, helium, or argon, during the process of sputtering. Palladium, as is well known, absorbs in favourable circumstances hundreds of volumes of hydrogen, and, as has been shown (McKeehan, *Phys. Rev.*, 21, p. 334, 1923), this results in a lattice distension of some 2 or 3 per cent. It is true that it is a long step from this to the 6 to 20 per cent. distension we have found in many cases—and this too in metals such as iron, nickel, and cobalt, which are by no means so notable in their gas-occluding properties as palladium; nevertheless, it is the only explanation we can offer at this time.

If the presence of such large volumes of gas in these non-magnetic films be granted, although the direct experimental proof of its existence seems difficult because of the very minute amount of material in a film a light wave or less in thickness, it is of interest to inquire if it is in the form of a chemical compound with the metal or not. This must of course be answered eventually, if at all, on the basis of proved stoichiometrical proportions. We cannot decide this at present, but we can, however, adduce certain evidence. Each of the three cobalt films sputtered in helium had exactly the same crystal dimensions—20 per cent. increase above the normal face-centred cubic cobalt (the cathode was a mixture of face-centred cubic and hexagonal)—in spite of somewhat different sputtering conditions. All of the seven iron films sputtered in helium had exactly the same crystal dimensions, apparently a swelling of nearly 22 per cent. above the normal. Ten different specimens of nickel, sputtered in different gases, had a common distension of 6 per cent., although with this metal there were other values which occurred in some specimens and not in others. It was possible in the above cases to reduce, by controlled heating, part of the specimen to the pure metal leaving the rest unchanged, as shown by the X-ray picture which showed both forms present at once. This is fair evidence against the idea of simply a solution of the gas in the metal. The case seems to be somewhat different from that of palladium: we sputtered this in hydrogen and found various distensions up to 3 per cent. It was possible, by suitable heating, to reduce the distension, *i.e.* the gas in the palladium, by any desired amount.

We regard this as evidence of a chemical or at least quasi-chemical union of the metal and the gas. Compounds with hydrogen would of course be possible, and with helium and argon at least not unthinkable. The loss of magnetism is possibly to be associated with a changed electron distribution in the metallic atom, due either to the influence of the chemical combination or simply to the increased distance of the atoms apart. (See also L. C. Jackson, *Phil. Mag.*, **2**, p. 86, 1926.)

We have been at some pains to forestall the most obvious point of criticism, which would be to the effect that small traces of oxygen in the residual gas might cause these metals to sputter as (non-magnetic) oxides which reduced on heating to the pure metal. Some colour is lent to this point of view by the fact that the lattice spacing of cobalt as deposited is almost exactly that of cobalt oxide. There are several reasons why we do not believe this view tenable: (1) We have taken great pains in purifying the gases, particularly as regards removing hydrogen and oxygen from the helium and argon: there was probably a trace of nitrogen in each. (2) If the metal, *e.g.* cobalt, is sputtered as an oxide, it must be of such a character as can be reduced to the metal by heating in a vacuum for a few minutes to, say, 350° C. This possibility is contradicted by chemical evidence, and experiments we have made on cobalt oxide indicate that such reduction is impossible. (3) There are minor differences between the lattice shown by the original cobalt films and cobalt oxide which clearly separate them. It would seem, nevertheless, as if we had here a cobalt helium compound very like cobalt oxide.

The work is to be continued with certain improvements, such as the use of fused quartz instead of glass, on which to deposit the films: also with better means for thorough outgassing and for extreme purification of the residual gases.

The Spectra of NH Compounds.

It is well known that the flame of ammonia emits several characteristic bands. The appearance of the bands is strongly influenced by the temperature of the source. Thus the spectrum of the cool flame of ammonia is dominated by the diffuse so-called α-group in the yellow region. In the spectrum of a hot source of ammonia, burning in the electric arc, the β-group with its intensity maxima at λλ 3370, 3360 is photographically by far the most intense. From investigations on the exciting conditions and on the structure of these bands, one may suppose that the very complicated α-group is emitted by the excited NH_3 or NH_2 molecules, or a mixture of both, as one can distinguish with some degree of certainty two different systems in α. Judging from some very distinct structural relations holding between the β-group and the long series of known hydride spectra, we refer the origin of this group to the NH dipole. This will be discussed later. Other bands of the ammonia-oxygen flame are referred by Eder to NO compounds. Very recently, K. Gleu, in an interesting paper on the chemi-luminescence of chlorine trinitride in hydrogen trinitride (*Zeits. f. Phys.*, 38, p. 176, 1926), reported some new bands of nitrogen hydride. From their symmetric positions around the β-group and their comparatively simple structure we suggest that they also belong to the spectrum of the NH dipole.

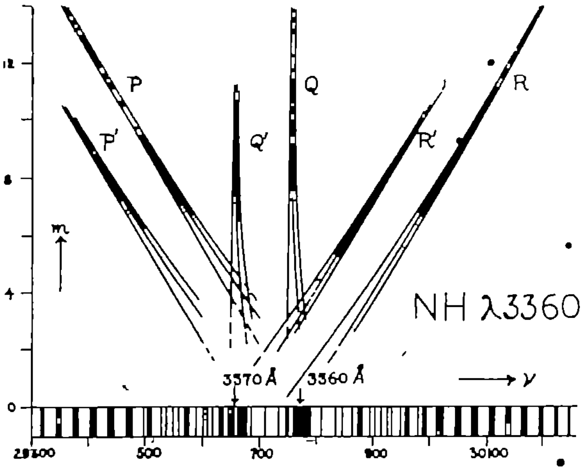

Fig. 1.

We have lately studied the structure of the β-group, using Fowler and Gregory's measurements (*Phil. Trans. Roy. Soc. London*, A, 218, p. 351, 1919) as well as our own, taken from spectrograms of high dispersion (1 Å.U. = 1·2 mm.). Fig. 1 gives a rough view of the system arranged in a ν-m diagram. The characteristic triplets on both sides of the intensity maximum at λ 3360 are shown as P- and R-branches, while the intensity maximum itself is supposed to be made up of the overlapping lines of the corresponding Q-branch. The long-wave component (Q_1), especially in the Q-triplets, thus causes the region which is still unresolved with a very high dispersion at λ 3360·31. As in the cases of many other band spectra, this arrangement gives rise to a 'combination defect' which has to be explained by assuming a separate set of rotational terms for the Q-branches *vis-à-vis* with those of the P- and R-branches. From a closer analysis of the spectral terms, it appears that the initial state contains an electronic triplet, while the final state is a singlet. The final state, however, includes a rotational triplet of unknown nature in which the very small term separation increases linearly with m ($\sim 0{\cdot}010\, m$). Accurate figures for the electronic frequencies cannot be obtained (~ 29750 cm.$^{-1}$) owing to the difficulties in computing the series down to their origins. If we denote by σ and ϵ the quantum numbers of the total electronic angular momenta parallel and perpendicular to the figure axis of the dipole, it appears from the analysis that the initial term contains distinct σ, ϵ components, while in the final state, $\sigma = 0$, $\epsilon = \frac{1}{2}$. The nuclear spacing of the molecule in its final state is $r_e = 1{\cdot}10 \times 10^{-8}$ cm.

The above statements are in agreement with the hypothesis on the appearance of Q-branches in band spectra, and also point to some clear relations holding between this spectrum and those of the hydrides as they appear in the periodic table. All the known hydride spectra are associated with electronic transitions of the type $S \longrightarrow S$ or $S \rightleftarrows P$. These two types can sometimes be distinguished from each other by the fact that bands of the first type contain only P- and R-branches, while those of the second type have Q-branches in addition. This seems to be a general rule holding for all band spectra. Consequently we assign to the β-group of the NH spectrum a ${}^3P \longrightarrow {}^1S$ transition, where ${}^3P$ separations should agree in magnitude with those in the spectrum of the preceding atom, here carbon, which spectrum, however, is still imperfectly known.

While the spectrum discussed above apparently forms the spectrum of the non-vibrating molecule ($n_1 = 0$, $n_2 = 0$), the secondary maximum at λ 3370 with the faint triplets on both sides of it can be explained in detail as the corresponding first vibration spectrum ($n_1 = 1$, $n_2 = 1$).

The triplets in the β-group are of the same type as those forming the bands of the second positive group of nitrogen. It is, however, interesting to note here that the regular alternation of intensity observed in the short-waved component (a narrow doublet) of the N_2 triplets has no counterpart in the NH triplets, the components here being all single so far as can be judged from our spectrograms. This also confirms the assumption of Mecke, according to which such anomalies are to be found in the spectra of symmetric molecules as H_2, He_2, HCCH, N_2 (see also Slater's hypothesis on this problem, NATURE, April 17, 1926, p. 555).

Icebergs in Relation to Water-Temperature.

IN an article in NATURE of Nov. 20, p. 750, which discusses means of enabling a vessel to detect the proximity of icebergs at sea, a remark is made which indicates that the attempt to do so by means of the temperature of the water has proved unavailing. When the conditions are considered it could scarcely be otherwise. I was impressed by this during two seasons spent in investigating the currents in Belle Isle strait, in 1894 and 1906, when the matter was looked into.

In that strait the surface water may warm up to 57° F. in summer, while the deeper water remains little above freezing point. Hence, with a heavy wind across the strait, the surface water may be driven to the leeward shore, allowing the cold under-water to come up to the surface. A vessel on its way through the strait might thus find the temperature so low as 45° or even 35° in the summer time, which is a large change compared to any lowering of the temperature by ice.

It is also to be noted that in currents at sea the velocity decreases from the surface downward; and an iceberg which may have a draught of 150 feet to 300 feet (as shown by the depth in which it grounds) will move at the average velocity of the current between the surface and that draught. Accordingly, there is normally a flow of surface water past an iceberg, due to difference of velocity, when it travels in a marine current. The only chill to the water is therefore in the tailing or wake, on one side of the iceberg, in the line of flow. Unless a vessel approaches towards that side it would detect no difference in the water temperature.

The amount of chill in the region of Belle Isle strait, in water which is already cold, was investigated with a boat, going close up on all sides of the icebergs. When the general surface temperature was 35·5° F. the water tailing from an iceberg was 35°, while on its other sides no difference was found. A small berg aground in a bay in which the surface temperature ranged from 34° to 34·5°, chilled the water to 33·5° close around it. In the case of a large iceberg (780 feet by 290 feet at the water-line, and aground in 57 fathoms) the water temperature, 37°, did not vary within 130 feet of it. Such small differences could not be considered as an indication of practical value, especially when within a few hundred feet of the bergs.

Nevertheless, Dr. H. J. Barnes was hopeful of more definite indications by means of his highly sensitive thermometer, especially near the meeting-place of the Labrador Current and the Gulf Stream, where the water is warmer and almost motionless. But a further feature was encountered under these conditions; for the water chilled by the iceberg sank vertically down from its sides. With an iceberg in relatively warm and still water there is thus theoretically a movement of the surface water inward towards the berg, instead of any spread of chilled water around it. The lowered density of the sea water due to dilution from the melting ice does not seem to counteract this, because of the rapid rate of increase in the density of water with fall of temperature.

When such conditions are understood, the uncertainty of any temperature warning against floating ice will be appreciated.

The Chromosome Number in *Dactylis glomerata* (Cocksfoot).

IT is only recently that the attention of cytologists has been directed to the ascertaining of the chromosome number in the herbage grasses. In a letter to NATURE of Dec. 11 (vol. 118), p. 841, Mr. Gwilym Evans states that he has discovered the number in the Lolium spp. and has given a tentative estimate of the number in the two varieties of *Festuca elatior*.

Whilst engaged at the Welsh Plant Breeding Station, Aberystwyth, in carrying out preliminary investigations on the genetical behaviour of *Dactylis glomerata*, it was thought expedient to ascertain the chromosome number of this species. The nuclear divisions, both somatic and meiotic, have been extensively investigated; the root-tips being selected as the most promising material for an examination of the somatic, whilst the meiotic divisions were studied in the anther.

The root-tips were fixed in Flemming's Solutions, in some cases a little modified. For the fixation of the anthers, Flemming's Solutions proved entirely unsuitable. Excellent fixation was, however, obtained with Bouin's Picro-formol and with Allen's modification of this solution. Belling's Aceto-carmine gave only indifferent results as a medium for chromosome counts on this species.

The conclusions drawn are entirely based on the examination of permanent slides of the root-tips and of the anthers. The number in *Dactylis glomerata* is clearly established as being twenty-eight in the diploid somatic nucleus of the root-tip and fourteen in the haploid nucleus. The count in the root-tip cells was made when the chromosomes were arranged equatorially on the spindle, and before the separation of the daughter chromosomes. In the case of the heterotype division it was much easier to count the univalents when in mid- and late-anaphase. Fourteen univalent chromosomes were readily distinguished. This number was again to be seen in the homotype division immediately following, the best stage for counting being the equatorial plate stage, just previous to the commencement of anaphase.

It is thus established that the chromosome number in *Dactylis glomerata* is fourteen in the haploid and twenty-eight in the diploid generation.

The investigation of the chromosome number in *Arrhenatherum avenaceum* and *Phleum pratense* is now proceeding. It is as yet too early to state definitely the number obtaining in these two species, but an examination of the root-tip of *Arrhenatherum avenaceum* (the indigenous form with swollen basal internodes is the one hitherto examined) enables me to state that the diploid number in this species is in the neighbourhood of forty.

It is hoped in the near future to state definitely the chromosome number of both these species.

Hyperfine Structure in the Neon Spectrum.

IN an investigation of the neon spectrum I have found that all lines, which arise from an *s*-term, have a component of shorter wave-length. The intensity of the satellite ranges from one-fourth to one-tenth that of the main line (according to a rough estimation). The separation of the components varies with the *s*-term concerned; for a $2s_2$ term it is 0·076 cm.$^{-1}$; for a $2s_3$ term, 0·054 cm.$^{-1}$; for a $2s_4$ term, 0·056 cm.$^{-1}$; and for a $2s_5$ term, 0·058 cm.$^{-1}$. The structure is apparently due to a multiplicity in the *s*-levels. There are also evidences of a fine structure in the *pd* series lines, but complete resolution has not yet been attained.

The fine structure of the neon-lines has a certain importance for their use as wave-length standards. In an inhomogeneous discharge the intensity of the main line will be weakened by self-reversal more than that of the satellite; thus with incomplete resolution of the structure the maximum intensity will be displaced towards shorter wave-lengths by increasing self-reversal. The fine structure must also be considered in absorption and intensity measurements. The question whether the neon isotope of atomic weight 22 emits the component of the neon lines is to be decided by an investigation of the Zeeman effect for the fine structure.

Structure of the Mercury Line λ4916.—This line has hitherto been found simple by all observers: it consists, however, of five components separated from the strongest members by the following intervals:

$$+0{\cdot}098 \text{ cm.}^{-1}\ (2),\ +0{\cdot}056\ (4),\ \pm 0\ (10),\ -0{\cdot}066\ (3),\ -0{\cdot}121\ (5).$$

Structure of the D_3-Line of Helium.—At the suggestion of Prof. Paschen the structure of the lines of orthohelium has been investigated. The intensity measurements for the line λ5876 ($2^3P_i - 3^3D$), which is usually regarded as consisting of two components with intensities 1 and 8, made it seem probable that this line was really a triplet with relative intensities 5 : 3 : 1, of which the two strongest components had not been resolved (MacNair and McCurdy, NATURE, 117, p. 159, 1926). The theory of Heisenberg (*Zs. f. Phys.*, 39, p. 499, 1926) requires a separation of the components ($^3P_2 - {}^3P_1$) of about 1/10 ($^3P_1 - {}^3P_0$). With the aid of the Fabry-Perot interferometer and a direct current discharge at the lowest possible pressure, the apparatus being cooled with liquid air, I have succeeded in resolving the components $^3P_2$ and $^3P_1$. The resolution was improved when the discharge tube was immersed in liquid hydrogen. The frequency differences are: $^3P_2 - {}^3P_1$, 0·075 cm.$^{-1}$; $^3P_1 - {}^3P_0$, 0·98 cm.$^{-1}$. The relative intensities have not been measured, but they apparently agree with expectation.

(Translated by R. A. Sawyer.)

Spinning Electrons and Protons.

THE remarkable results obtained within the past fifteen months by employing the spinning electron in Bohr's atomic model suggest the question whether it may not be necessary to suppose that the proton also is capable of a quantised spin. Although the analytical difficulties in applying the new quantum mechanics to this problem may be considerable, they may not be too great to be overcome by mathematicians. There seem to be several arguments in favour of such a hypothesis. If, as is generally assumed, the proton is the positive electron, it seems natural to suppose that if the negative electron can spin with unit angular momentum the positive electron may do the same. Again, it may be easier to understand the structure of a complex nucleus if the units of which it is composed can act as elementary magnets. Prof. Duane has attempted to explain corpuscular emission from a radioactive nucleus on these lines. Finally, recent experiments on the deflection of protons and alpha particles in collision with an atomic nucleus seem to lend support to the idea of a magnetic field in the vicinity of a nucleus.

A spinning electron is one example of a *magneton*. My main object in this letter is to remind readers of NATURE that a quantised magneton was first described in these columns (vol. 92, p. 165, Oct. 9, 1913) by Prof. G. B. McLaren, a victim of the War. "The natural unit of angular momentum," postulated by Nicholson and employed by Bohr, "actually exists. It is the angular momentum of the magneton." It is true that McLaren's magneton is in one sense not spinning, for he rejected entirely the idea of magnetic or electric substance, and the angular momentum is located in the electromagnetic field. It is true also that he assumed his magneton to represent a *positive* electron, but this choice was, as he himself pointed out, an arbitrary one (*Phil. Mag.*, vol. 26, pp. 667-8, 1913). The essential fact remains that the idea of a magneton having angular momentum determined by the quantum condition was clearly stated, and was thereafter employed without question by other writers. It may be found, for example, in my paper on an atomic model with a magnetic core (*Phil. Mag.*, vol. 29, p. 719 footnote, 1915), in connexion with a positive electron, and in the discussion of the 'ring electron' (or Parson magneton) at the Physical Society of London on Oct. 25, 1918 (*Proceedings*, vol. 31, p. 61, 1919).

It is almost needless to add that there is no intention of detracting in any measure from the credit due to those who have recently been so successful in applying the spinning electron in connexion with the Bohr atom. There is satisfaction in finding that ideas for which the time was not ripe ten or more years ago now have a wide field of application, and are accepted by the leaders in physics, who were at one time unwilling to ascribe structure of any kind to the electron.

Rotation of Dielectric Bodies in Electrostatic Fields.

The rotation of dielectric bodies when suspended between the knobs of a Wimshurst machine was first observed by me about a year ago. Since then the phenomenon has been studied by Messrs. L. G. Vedy and G. Gowlland and other pupils of mine. Experiments illustrating the phenomenon were shown at the recent Physical and Optical Societies' exhibition at the Imperial College of Science and Technology, particulars of some of which are given below.

Pieces of paraffin wax (including a sphere of 5 cm. radius), ebonite, sealing-wax, and a glass beaker rotated when suspended between the knobs of a Wimshurst machine. A covering of metal foil prevented rotation.

Brass spheres covered with paraffin wax rotated, the greatest rate being attained by the sphere with the thickest wax layer. Better results were obtained with bodies mounted on bearings (steel needles in glass sockets) as this arrangement prevented the bodies from swaying and striking the knobs.

By using an alternative gap it was shown that rotation did not occur in the absence of a brush discharge. Also sparking usually decreased the effect.

The presence of a charge on the bodies was shown by using a proof plane and an ordinary gold leaf electroscope. When the paraffin wax sphere was mounted symmetrically between two nearly similar knobs the charge was shown to be very small.

When the bodies were suspended inside a glass beaker or between ebonite plates, which shielded them from the discharge, rotation did not occur; but the ordinary orientation phenomenon was quite marked.

The general conclusion arrived at so far is that the phenomenon is due to the effect of the discharge, but that it is not wholly a surface effect. The influence of the presence of moisture on the surface and of the air surrounding the bodies, *inter alia*, deserve careful examination and further experiments are contemplated.

Two-way Communication with the Antarctic.

Contact with the Norwegian whaler, *Sir James Clark Ross*, call sign AQE, by the south shore of the Ross Sea, 78° 30′ south latitude, was obtained by C. W. Goyder from the Mill Hill School station, 2 SZ, on Jan. 30, and the messages exchanged constituted the first two-way communication with the Antarctic. Contact was again established at 8.30 A.M. to-day with the double object of putting the whaler in touch with a Norwegian station and of getting particulars of the ship *C. A. Larsen*, with the call sign ARDI, which is within a few miles of AQE.

Two-way working was easy and expeditious, and the first object was partially secured, for the signals of LGN (the Bergen Radio Coast station) and of AQE were both of good strength here. They were unable to hear one another, but an arrangement was made with each that they should attempt to get in touch with one another at 7.30 A.M. to-morrow (Feb. 7). Meanwhile AQE reports having been in touch yesterday with LA.IX (J. O. Berven, Stavanger).

The ship ARDI was thought to be a scientific expedition because the north-bound expedition into Norwegian waters, organised last summer from Cambridge, had the call sign ARDS, but was reported this morning by AQE to be another Norwegian whaler in their vicinity. ARDI was heard calling, but communication was not established. Direction-finding work, alluded to by AQE, is being carried on for the purpose of keeping in touch with the whaling boats in foggy weather.

The Fayum Lakes.

The question of silting which is raised by Mr. G. W. Grabham (Nature, 118, 911, 1926) depends on the velocity of the water. In water that is slackening, silt will be dropped; but if the flow is quickening, it will be carried on. In the case of the Fayum channel an inflow during two or three months had to make up for four or five feet of evaporation and also a previous outflow over a large area. As the water in this six miles of channel had therefore a gradient much greater than that of the Nile, it is unlikely that any silting would be caused during the inflow. During the stationary periods only suspended silt would be dropped, which only amounts to one inch in 15 or 20 years. During the outflow no rolled silt would be carried, as it would have slipped into deeper water in the lake. It does not therefore seem likely that any fluctuations of level could be caused by silt obstruction. Two queries that are asked may be noted here: (1) The high level taken appears to be due to a pre-human estuarine condition of the Nile; (2) there is no question about the sources of the flints which I bought in the Fayum, as they are like those found there, and none in similar condition are found in the Nile valley.

The Supposed Law of Flame Speeds.

Mr. A. G. White, in his letter in Nature of Jan. 8, p. 51, correctly recalls the fact, which we discussed fully in our original publications in the *Journal of the Chemical Society*, that deviations from the law of speeds may be expected if one of the combustible gases in a complex mixture interferes with the burning of another. The deviations are, however, small and their nature can be predicted.

The behaviour of mixtures, near the limit of inflammability, containing ether vapour or carbon disulphide, to which Mr. White refers, was considered during the discussion of Prof. Jorissen's paper at the meeting of the Faraday Society in June. We do not attach any importance to such mixtures from the point of view of the law of speeds, for the reason that they exhibit the peculiar phenomena of the 'cool flame' (cf. White, *J.C.S.*, 115, 1462, 1919), which is quite distinct from a normal flame.

Matrix and Wave Mechanics.

By R. H. Fowler, F.R.S.

In an article on spinning electrons (Nature, Jan. 15, p. 90) it was stated that recent progress in atomic physics is mainly due to two primary ideas: the use of a better model of the electron and of a better formal mechanics more suited than classical mechanics to the description of atomic phenomena. The changes and successes consequent on the adoption of this new model of the electron have already been described. We shall try here to give some sort of description of the ideas of the new mechanics and some of the successes to which they have led. We shall try at the same time to exhibit the two independent lines of thought which have led separately to the same new system of mechanics, but by such widely divergent paths that they have justifiably received the different names of *matrix mechanics* and *wave mechanics*. The equivalence of these two systems is perhaps the most striking and satisfactory feature of the present development.

The really fundamental features of atomic systems, as analysed with the help of the older quantum theory, are described in Bohr's first two postulates—the existence of stationary states and the frequency relation $E_1 - E_2 = h\nu_{12}$. Of these, the first is perhaps the most fundamental characteristic of all, for it is this characteristic, properly viewed, which imposes on us the particular change of the laws of mechanics which has had to be made. To describe an atom and its interaction with radiation we may agree (apart almost from all theory) that we must have (1) a set of stationary states, (2) a set of interconnexions between the stationary states which we may call transition probabilities. Collision interactions have proved harder to analyse with certainty than radiative, but we all agree that they fit perfectly into the same scheme. Our requirements, therefore, are very different from anything that can be satisfied by a system of particles obeying classical dynamics. Such systems do not have discrete stationary states. This difficulty was provisionally turned by Bohr by his third postulate ($J_k = n_k h$) which, of course, had striking successes. But these were only partial, for though the postulate gives us stationary states it cannot give us transition probabilities, except on occasions by temporary devices of interpretation based on the correspondence principle. Transition probabilities are essentially connexions between two states, whereas all the characteristics of a classical motion are functions of the one state alone. In short, a classical system in any (multiply periodic) state can be fully described by Fourier series, the coefficients and fundamental frequencies of which are functions of the parameters defining the state. An atom cannot be so described. Its coefficients must always be functions of two states, not one. Now that we know the answer it seems (as it should) very obvious—it is not a Fourier series or one-dimensional array of periodic terms with constant coefficients, but a matrix or two-dimensional array of such terms which is required to describe the atom. Any term of such an array depends on two integers m and n, defining the two states of the atom which the term connects or to which it belongs.

It may be helpful to interpolate here a few remarks on matrices. Matrices were introduced into algebra by Cayley, and form a branch of that subject interesting in itself, but hitherto not very familiar to physicists. The matrices with which the physicist is now concerned are, like determinants, square arrays of symbols, but, unlike the determinants, the matrix is not multiplied out. Instead, each symbol or term is regarded as a constituent member of the whole matrix. Thus, if we say that two matrixes are equal, we mean that each term of the first is equal to the corresponding term of the second. Matrices can be handled by a set of algebraic rules rather like the rules of the algebra of ordinary numbers. Many results go over into the new calculus unaffected, but there is one striking difference. The law of multiplication, which, loosely speaking, is that by which two determinants are multiplied together, is non-commutative—when matrix x is multiplied by matrix y the result, xy, is a matrix of which the terms are *not* the same as those of yx. The difference between these products provides exactly the necessary gap in the algebra into which the quantum theory can insert itself.

The question then arises, can one formulate a dynamics of matrices which is a natural generalisation of classical dynamics with classical dynamics as its limit, and yields rules for calculating the terms of any relevant matrix just like the classical rules for calculating any term of a Fourier series? Something, of course, must be given besides the laws of dynamics—that something is classically the potential energy function of the system, giving the field of force in which the particles of the system move, and we may demand that the same data shall suffice in the new form. This is equivalent to asking that everything shall be derived by direct unambiguous calculation from the Hamiltonian equation of the system, using generalisations of the classical laws. The quantum conditions of the older theory disappear and the essential h now enters the equations via the new non-commutative multiplication of conjugate canonical variables p and q, in the form

$$pq - qp = \frac{h}{2\pi i} \quad (i = \sqrt{-1}).$$

The answer to the opening question of the paragraph is, yes! Everything seems to work out as it should, as the work of Heisenberg, Born, Jordan, Dirac, and Pauli has abundantly shown.

The need for the matrix mechanics can nowadays perhaps be put forward as convincingly as possible in the manner adopted above, which shows that its constructs have direct physical counterparts. Every term in a matrix represents something ideally observable. Heisenberg was originally led to formulate the matrix mechanics by a deliberate development of a demand for ideal observability of the counterpart of every construct, a demand which we have just seen to be satisfied by the matrix mechanics. He pointed out that the selected mechanical orbits of the older theory cannot satisfy this demand, because they cannot even ideally be directly presented to us for measurement. On the other hand, the frequencies and intensities of the light emitted, scattered, or absorbed by an atom, are observable in just this way. The older theory tried with partial success to derive the observed frequencies and amplitudes from the abstract theoretical ones. Heisenberg's new method was to do away entirely with every theoretical construct which could not be directly related to an observable property of the atom. Perhaps the distinction set up cannot always be rigidly maintained. It served at least to suggest to Heisenberg that we should stop trying to *interpret the results* of classical calculations and instead should *re-formulate the equations* of the motion, and re-formulate in such a way that every symbol has a physical meaning, just as in an astronomical problem in the classical mechanics. Physical meaning is no longer to be confined to interpretations of the final result. Since the matrix is the mathematical construct with the properties of any natural atomic co-ordinate, Heisenberg's idea led at once to the formulation of the matrix mechanics.

An entirely different point of view has been developed by Schrödinger. Following up the speculations of L. de Broglie, in which he drew an illuminating analogy between the free motion of particles such as electrons and groups of plane waves of a special type, Schrödinger came to examine more closely than before the analogy between mechanics and optics which formed in fact the basis of Hamilton's whole treatment of mechanics. The analogy due to Hamilton is that between the dynamics of particles and geometrical optics, let us say between the paths of particles and of light *rays*. We all know, however, that the propagation of light can only be adequately discussed by the optics of rays so long as the wave length of the light is very small compared with the dimensions of every obstacle encountered. Once this condition is broken diffraction effects occur, and we need the *wave* theory of physical optics with which to describe the phenomena. To this breakdown of the *ray* theory of light there has been hitherto no Hamiltonian analogy. In setting out to find such an analogy Schrödinger has formulated what we now call the wave mechanics. We shall not attempt here to describe his arguments but only the results. Instead of thinking of an atom as a set of particles, we retain from the particle picture only the potential energy V, and the masses of the particles, m. The atomic motion can be derived from a wave equation of the usual type

$$\text{Div. grad. } \psi + \frac{4\pi^2\nu^2}{u^2}\psi = 0.$$

In this equation u is the phase-velocity of waves of frequency ν, and ψ and its operators must probably be taken to refer to the configuration-space of the whole system, of dimensions equal to the number of freedoms. The Hamiltonian analogy demands, moreover, that u, E, the energy, and ν shall be connected by the relations

$$\nu = \frac{E}{h}, \quad \frac{1}{u^2} = \frac{2(E-V)}{E^2}.$$

A universal constant of action h enters naturally into the analogy; that it has exactly Planck's value is of course only fixed at a later stage. The resulting partial differential equation,

$$\text{Div. grad. } \psi + \frac{8\pi^2}{h^2}(E-V)\psi = 0, \quad . \quad . \quad (1)$$

must be conformed to by all wave forms which correspond to states of the atomic system with energy E. The wave function ψ must naturally be subjected to continuity and boundary conditions. To represent a possible stable state of the atom it is natural to suppose that ψ must satisfy (1) and besides be one-valued, bounded, twice differentiable over the whole configuration-space, and vanish at infinity. So far there has been no mention of discrete states. Any value of E would be admissible for which a suitable ψ exists. But we come now to the most beautiful point of Schrödinger's theory, for it appears in general that suitable ψ's only exist for a set of discrete values E_n of E, perhaps together with continuous ranges of values as well. The E_n are the energies of the various stationary states and the corresponding ψ_n the wave functions of these stationary states which specify what the atom is then doing.

For the simplest example let us take the linear harmonic oscillator. The wave equation then becomes

$$\frac{d^2\psi}{dx^2} + \frac{8\pi^2 m}{h^2}(E - 2\pi^2\nu_0^2x^2)\psi = 0,$$

where ν_0 would be the classical frequency of the oscillator. The smallest value of E for which a satisfactory ψ exists is $E_0 = \frac{1}{2}h\nu_0$, and then

$$\psi_0 = e^{-2\pi^2 m\nu_0 x^2/h}.$$

We observe that ψ_0 never vanishes, so that the corresponding wave is of infinite length and has no finite nodes. The next solution is $E_1 = \frac{3}{2}h\nu_0$, and then

$$\psi_1 = 4\pi\left(\frac{m\nu_0}{h}\right)^{\frac{1}{2}} x e^{-2\pi^2 m\nu_0 x^2/h}.$$

The wave has now one finite node at $x = 0$. The following values of E are $E_n = (n + \frac{1}{2})h\nu_0$, and the corresponding ψ_n have each one more finite node, so that the wave-length of the atomic oscillation gets shorter as n increases, and tends to zero as n tends to infinity.

For the earlier values of the set E_n it is impossible to speak of orbits and point electrons. For the later values the behaviour of the simple example above is general. The wave mechanics then degenerates, so that from a group of waves of various frequencies and directions we can build up a small bundle of waves, in phase only in the immediate neighbourhood of one point. This point of coincidence in phase will move with the group-velocity of the group of waves, and actually in the limit propagates itself along an orbit obeying the laws of classical mechanics. In this limit orbits and point electrons again have a meaning.

Two constructs more different in conception than the matrix mechanics and the wave mechanics can scarcely be imagined, except that they are both generalisations of classical mechanics, retaining classical mechanics as a common limit. Schrödinger has suggested a physical analogy which perhaps shows their connexion. Suppose we have a stretched string of variable density. Then the wave mechanics finds the various ways in which the string can vibrate, and determines, *inter alia*, the nodes of the possible vibrations. These nodes are what we want, and the matrix mechanics is a calculus which determines them directly. It is perhaps not surprising that the ignoration of the rest of the string should lead to an unfamiliar procedure. Both schemes appear to make just those changes in the energy values of the stationary states which the facts were known to require. But the connexion between them is very deep and amounts almost, if not quite, to complete equivalence. To illustrate the connexion we must temporarily become technical. The change made in the wave mechanics is equivalent to deriving from the ordinary Hamiltonian equation of the system

$$H(q, p) - E = 0,$$

where (p, q) are canonical variables, the wave equation

$$\left[H\left(q, \frac{h}{2\pi i}\frac{\partial}{\partial q}\right) - E\right]\psi = 0 \quad . \; . \; . \; . \quad (2)$$

for the wave function ψ, instead of deriving the Hamilton-Jacobi equation

$$H\left(q, \frac{\partial S}{\partial q}\right) - E = 0$$

for the 'principal function' S. Equations (1) and (2) are different versions of the same equation. The p thus become differential operators. The close connexion between the operator algebra required in the wave mechanics and the matrix algebra of the matrix mechanics can be seen by a simple example. The commutative rule of the matrix mechanics already given becomes in the operator calculus, with $\frac{h}{2\pi i}\frac{\partial}{\partial q}$ for p,

$$\frac{\partial}{\partial q}(q\psi) - q\frac{\partial \psi}{\partial q} = \psi,$$

which is obviously satisfied. This example may perhaps remove the element of surprise at finding that Schrödinger has shown how to derive from the complete set of wave functions ψ_n for any atom a definite corresponding set of matrices which solve the problem of the same atom in the matrix mechanics. Whether the converse is true and the equivalence complete is less certain. At the moment it seems that matrix solutions may be possible which are not represented in the wave mechanics. The case in doubt is the rigid symmetrical top, for which in the matrix mechanics solutions appear to be possible both with whole and half quantum numbers, while only the former are allowable in the wave mechanics.[1]

It is probably futile at this stage to attempt to decide which of the new forms is the more fundamental. It will of course be found by the majority of workers that the wave mechanics, owing to the greater familiarity and convenience of its algebra, is the more powerful tool for solving any particular problem.

Let us now take a last glance at what the new mechanics in either form has done for us. In every case yet worked out completely, it has given us just exactly those changes of quantum numbers from the older theory, which had been forced on us already by the facts. Thus with the spinning electron the general theory of spectra is now an orderly whole. Weights, magnetic displacements, structure rules and intensity rules for multiplets and the complete form of the spectrum of the hydrogen atom are now at last correctly predicted by the theory. (It must be recorded that this requires us to assume that the spinning electron can be likened to a top with half quantum numbers. This assumption may require a trivial alteration of the wave mechanics in view of the wave-theory of the top.) But the wave mechanics has done more than this. It has already led us successfully to the attack of problems in which the results of the older theory could not be described as qualitatively correct. Such problems are, for example, the calculation of the exact values of the higher terms of the spectrum of neutral helium and the calculation of the terms of the positive molecular ion of hydrogen. Of the latter it is too early to speak with certainty. The successful calculation of the higher terms of ortho- and par-helium by Heisenberg marks outstanding progress. In the course of this work he has been led to study with success the phenomena of resonance between similar atoms or between the necessarily similar electrons in one atom. These phenomena promise to be of outstanding importance in the further development of the theory, and have already thrown much light on Pauli's important empiral principle that no two electrons in an atom can have the same quantum numbers, and on the problems of statistical mechanics. Nor is this all. A successful attack has at last been opened on the quantum theory of collisions and on non-periodic orbits, largely by Born and Oppenheimer.

However abstract the new mechanics may yet seem to us, however incomplete our grasp of its fundamental principles, it is impossible to overestimate its value to theoretical physics. We have, at least in the simpler problems, ceased to grope, and fudge our results until they are useable. We have at last a general dynamical method to apply to any atom, which is capable of yielding us by direct calculation any result for which we may ask. We cannot yet expect all such results to be right, but we are confident that only minor modifications and generalisations will be required.

---

An interesting survey of wave mechanics is given by L. de Broglie, *J. de Phys. et le Radium*, 7, 321 (1926). I have not attempted to enumerate the primary references, which will be familiar to students of the quantum theory.

The Principles of Biological Control in Economic Entomology.[1]

By Dr. R. J. Tillyard, F.R.S., Chief of the Biological Department, Cawthron Institute, Nelson, N.Z.

II.

The Control of Injurious Weeds.

We turn now to the second problem, in which the introduced plant, not the insect, is the enemy of man. We have to decide the question whether it is advisable to undertake researches on the lines of introducing insects which will feed upon and tend to check the growth of those plants which, in new lands like Australia and New Zealand, have got beyond the control of man and threaten to swallow up large areas of valuable land.

I think the first point, undoubtedly, must be to insist that the method should only be used where a solution cannot be attained in any other direction. All are agreed that the unrestricted importation of plant-feeding insects into a new country is highly undesirable. The problem awaiting solution must be sufficiently grave in its nature to warrant the attempt being made with adequate safeguards, and under the guidance of the most competent experts obtainable.

We can turn again to the Hawaiian Islands for the pioneer experiments in this direction and learn very valuable lessons from them. The first attempt at biological control of a weed was that made in Hawaii on Lantana. This weed was attacked by the introduction of a considerable number of its natural insect enemies from Mexico. The result has been that it is prevented from seeding and has been successfully restrained from spreading all over the islands. Most fortunately for the experiment, none of the introduced insects has proved detrimental to crops or other cultivated plants, with the single exception of one species which occasionally does slight damage to the egg-plant or Aubergine. Considering the absence of the safeguards which I have elsewhere laid down as indispensable in these experiments, the result must be considered a lucky one rather than a strict precedent to follow.

Further experiments are now being carried out in Hawaii on the control of nut-grass by introduction of certain insect enemies from the Philippines, and also on the control of the Mexican weed 'Pamakani.' These are being carried out with good safeguards, and the results will be awaited with much interest.

I now come to the most remarkable attempt so far made in the direction of control of a noxious weed by insects, namely, the prickly pear campaign in Queensland and New South Wales. The prickly pear, *Opuntia inermis*, was introduced into eastern Australia long ago as a botanical curiosity, and was even propagated and distributed in pots to visiting squatter's wives. When these ladies tired of it as a pot plant it was thrown out. But instead of dying, as an ordinary plant would do, it proceeded to take root and multiply exceedingly. The luscious fruit were fed on by many species of birds, and the ripe seeds were carried far and wide in their droppings. This went on until about thirty million acres of land had been put out of cultivation by the pest, and the rate of increase was about one million acres per annum.

Then at last the long-suffering Australian populace raised its voice and demanded that something should be done. A Prickly Pear Board was set up, and the first attempts to control the pest were carried out along chemical lines, resulting in the discovery of certain poisonous gases which could be liberated over the infected areas, destroying the weed. This method, however, failed, as the cost of manufacture and application of the remedy proved far too high. Failure also resulted from all attempts to utilise the pest commercially; the water content was found to be exceptionally high, the quality of the fibre very poor, and the fodder value very low. Thus the vision arose of eastern Australia becoming in about a hundred years time a vast desert of prickly pear, with a few walled cities alone holding out against it. Then the demand for a remedy became so insistent that the natural prejudice against the introduction of insect enemies was at last overcome, and an organised attempt was made to deal with the pest in this manner. Prof. T. Harvey Johnston took charge of the work, which was later on further advanced under the charge of his original assistant, Mr. W. B. Alexander. These men travelled far and wide in the warmer parts of America to find insect enemies of the pest, and large consignments were shipped to Australia. They were then placed in special insectaries and tested out on all varieties of prickly pear and also on a large number of important economic plants.

It is interesting to note, as showing the high degree of specialisation attained by cactus-feeding insects, that not one of the many species introduced could be induced to feed on any other kind of plant; indeed, a number of the species would only eat a single variety of Opuntia and would not even change to a closely allied and botanically scarcely distinguishable species. A few larvæ, faced by the 'starvation test,' made slight attempts to eat unaccustomed plants, but the result in each case was severe indigestion followed by death.

The first Opuntia-feeding insect experimented with was the cochineal insect, *Dactylopius indicus*. It entirely destroyed some thousands of acres of one species of prickly pear, *Opuntia monacantha*, but was quite unable to feed upon the allied pest pear, *Opuntia inermis*. A search was therefore made for other species of Dactylopius, and finally *Dactylopius tomentosus* was found capable of attacking *O. inermis*. This little insect is now being distributed in enormous quantities through the infested districts, and is doing wonderful work in helping to destroy the pest. Though it does not do equally well in all districts and under all the varying conditions, yet it is now generally admitted that this species will prove one of the chief factors in the control of the pest.

---

[1] Continued from p. 205.

Of many other species studied, the most promising appear to be the large coreid bug *Chelinidea tabulata*, the moth *Cactoblastis cactorum*, and perhaps the large longicorn beetles of the genus Moneilema. Large supplies of these insects are being reared in the insectaries, and it will be interesting to watch the progress of events when they are liberated.

It is of special importance to note that, in spite of the immensity of the insect fauna of eastern Australia, only one enemy has so far made its appearance in the field, namely, our old friend *Cryptolæmus montrouzieri*, the well-known enemy of mealy-bug. This lady-bird beetle has begun to attack *Dactylopius tomentosus*, but, so far, it has been found that the latter can more than hold its own, as it starts earlier and increases more quickly than its rival.

To sum up, it appears to be the general opinion in Australia that this formidable problem is in process of solution by means of the biological control gained by insect enemies over the pest.

This brings me logically to the consideration of the problems of weed-control which brought me to Europe. The most pressing of these for New Zealand, and to a considerable extent for Australia also, is the control of blackberry, *Rubus fruticosus*. The extent of the infestation in New Zealand may be judged by the saying current on the west coast of the South Island that they have only one blackberry bush, and that is 200 miles long. Certain areas in the North Island are almost as badly infested also. Not only does this terrible weed, originally introduced for its luscious fruit, spread vegetatively underground, so that each little plant soon grows into a great thicket, but the introduced European birds, especially the blackbird, feed ravenously on the fruit and so carry the seeds far and wide in their droppings. Nobody who has not seen this pest under the conditions prevailing in New Zealand to-day can really understand the menace that it offers to our civilisation. It seems simple to advocate 'closer settlement' and 'more careful cultivation' as the best methods of control; but when the extent and inaccessibility of the vast mountain fastnesses captured by the blackberry, from which with ever-increasing vigour it is spread far and wide over the richer lands, are realised, it will be understood that the hard-working men who are being driven off their farms after years of toil against this weed demand something more than this kind of advice.

The general insistence on something being done has led the Cawthron Institute to consider the taking up of this admittedly difficult problem on the lines of biological control. The chief difficulty is the central position occupied by the genus Rubus in the great natural order Rosaceæ, to which most of our finest economic plants belong. Thus the risk of damage to other valuable plants is appreciably higher than in the case of prickly pear or Lantana, and the safeguards imposed against the chance of such injury must be made correspondingly more severe. We will not even consider the introduction of any insect which is known to feed on plants other than Rubus, and we require very severe testing of these on a long series of native and introduced plants before we can consider their liberation.

Another bad weed which has taken possession of a very large area of ground in New Zealand and parts of Australia is gorse or furze, *Ulex europæus*. It is, however, a useful hedge plant, and, when young, provides good fodder for sheep; also, being leguminous, it improves the soil by the formation of nitrogen nodules. The problem of controlling gorse is therefore one of preventing it seeding, as it is the bursting of the seed-pods which is the main method of spread of this weed. This problem, I am glad to say, appears to have a fairly simple solution, for there are in England two or three insects which live wholly within the seed-pods of gorse and broom, and thus prevent them seeding without doing further injury to the plant.

Ragwort, *Senecio jacobæa*, is a poisonous plant which is becoming exceedingly abundant in New Zealand. When this plant is eaten by horses or cattle, cirrhosis of the liver results, ending in death, and no remedy is known for it. The control of ragwort by its insect enemies appears to be a feasible proposition, and is being undertaken by the Cawthron Institute at the present time.

St. John's wort, *Hypericum perforatum*, would scarcely appear likely to people in England to become a weed of importance. Yet it has so increased in size and vigour in parts of Victoria as to become a very serious menace, and the careful study of the possibility of controlling it by insects is one of the tasks which I have undertaken during my visit to England.

In conclusion, I would like to emphasise again the Imperial point of view in these researches. There are a large number of weeds introduced into various parts of the British Empire which we tolerate without having much idea of how far they rob us of the products of our labour. It has been calculated on a conservative basis that 10 per cent. of the world's crops are lost annually through the depredations of insects. I would like to ask whether anybody has attempted to make an estimate of what percentage of the Empire's crops are lost annually through the encroachments of noxious weeds? Think of the thirty million acres in Australia put entirely out of action by prickly pear, and the huge areas of cultivable land in New Zealand now 'going under' to blackberry and bracken-fern. Moreover, can we say that any weed, tolerated to-day as of no importance, may not in a few years time become a menace as great as the apparently harmless St. John's wort?

I declare emphatically that the menace is a most serious one in many parts of the Empire, and that we run the serious risk of being judged a race unfit to occupy these great areas, to the exclusion of other races, if we are going to allow them to 'go under' in the grip of introduced noxious weeds. The position demands the most careful consideration from those in responsible positions. Nothing less than an Empire-wide campaign will, in my opinion, suffice.

The Telephone.

In June last, Sir Oliver Lodge read a paper on the history and development of the telephone to the Institution of Electrical Engineers.[1] The occasion was the jubilee of the invention of the telephone by Graham Bell. The lecturer remembered Graham Bell speaking to the Physical Society of London in 1877. He was impressed by his clear and precise articulation. Graham Bell had devoted himself to the accurate production of human speech not only by his own lips and larynx but also by instrumental means. It is reported that he once said that it was fortunate that he was not a scientifically trained physicist; for if he had been, he would probably have thought that an articulating machine of a simple character was an impossibility. Talking machines had been invented before, but they were very complicated arrangements for producing vowel sounds. In this respect they were unlike the apparatus devised so successfully in our own day by Sir Richard Paget.

Graham Bell's machine took the sounds emanating from the human voice and sought to reproduce them at a distance by electrical methods. The way in which he found that this could be accomplished was surprisingly simple, and on Mar. 10, 1876, the first telephone worked successfully. Sir Oliver recalls how Kelvin showed two of Bell's early instruments at the British Association meeting in Glasgow, and how enthusiastic he was over the marvellous discovery. In these early days the same instrument could be used as a transmitter or a receiver. All the energy put into the circuit, therefore, came from the voice. Very soon, however, the Edison carbon and the Hughes microphone transmitter were invented, batteries were introduced, and the transmission was greatly improved.

When Clerk Maxwell first heard of the telephone, he pictured it in his mind as some instrument of marvellous ingenuity and constructive skill, as much excelling the siphon recorder as the recorder excelled an electric bell. When it first came over he has described his disappointment at its humble appearance, a disappointment only partly relieved by finding that it was able to talk. In this connexion Sir Richard Paget relates how, when Kelvin was staying with Lord Winchelsea, notice arrived that a talking machine, sent by Graham Bell, was coming. Lord Winchelsea dispatched a farm wagon to the station to collect it.

In 1888, Heaviside emphasised the similarity between Lodge's observations on electric waves in wires and Hertz's discovery of waves in free space. They both measured wave-lengths by reflecting them and converting them into stationary waves. Sparks were first used as detectors, but they were given up in 1890 in favour of the coherer principle, which was independently rediscovered and improved by Branly, who used iron filings and smeared metallic filings. This method was used in the earliest radio experiments. The discovery of the rectifying power of crystals and thermionic valves in the early years of the present century enormously improved the power to transmit speech and music, and improvements are still continually being made.

Wired and wireless telephony are constantly tending to approximate to one another. It is well known that by the use of accurate tuning and syntonised circuits it is possible to select from the multitude of disturbances in the ether only those of a given frequency. In practice, each sending station sends out carrier waves of definite wave-lengths, the voice modifying slightly the shape of these waves. This principle, so extensively used in broadcasting work, can be used for transmitting many telephone messages simultaneously by the same wire. Graham Bell also attempted to use this system in his harmonic telegraph.

In the transmitter and receiver we make use of Faraday's discovery—now nearly a century old—of the induction of currents by moving magnets. The transmitter may be regarded as a kind of dynamo and the receiver as a kind of motor. The transmission takes place by alternating currents flowing round the circuit. Owing to resistance, much of the electric energy is converted into heat. This leads to attenuation of the signals. The circuit also possesses capacity, and this Kelvin took theoretically into account. Heaviside next completed the practical theory by taking the inductance into account, and this led to the discovery of the distortionless circuit. Finally, Pupin persuaded American business men to construct 'loaded cables' and long-distance telephony was born.

Fleming's invention of the valve detector, further improved by Lee de Forest, has put into our hands an automatic relay of surpassing docility. Long-line transmission can be attained by a succession of short lengths of land line connected together by valve relays. The currents from the sending stations can now be sent great distances before they are relayed on with fresh energy. The American Telephone and Telegraph Company has in this way effected admirable speech transmission across the American continent.

In radio communication there is little attenuation and distortion. In free space there would be none. The theory of wave transmission in free space is extremely simple. It is only when matter is present that complications are introduced. It is true that there are many things which still seem mysterious to us, but there seems to be nothing that will ultimately be wholly unintelligible. We have bridged the Atlantic with radio telephony and can look forward to the time when sounds will veritably go out unto all lands and be heard by all who care to listen to them. "The progress of science is based upon faith in the ultimate intelligibility of everything: and so far wisdom has been justified of her children."

Obituary.

SIR ALFRED SEALE HASLAM.

BY the sudden death of Sir Alfred Haslam on Jan. 13 at the age of eighty-three years, Great Britain loses one of its principal pioneers in the development of the practice of refrigeration. More than any country, Great Britain depends on its overseas food supply, and the maintenance of that supply is only possible to-day through the application of artificial cold. Sir Alfred Haslam was one of the first British engineers to manufacture refrigerating machines, and the success of his work was recognised so long ago as 1888, when he received the freedom of the City of London for "services rendered to commerce."

The production of cold by artificial means can be traced back to Cullen and Leslie, and an important step was taken by Dr. Gorrie of New Orleans, who about 1845 caused compressed and cooled air to expand, working a piston in a cylinder. Other experimenters about that time used either ether or sulphur dioxide; but little progress was made until the mechanical theory of heat had been developed. The earliest attempt to preserve a cargo of meat by ice was made in 1860, but proved a failure. In 1876 the French worker Charles Tellier directed the fitting-out of the *Le Frigorique* with refrigerating apparatus for running between France and Buenos Ayres. Other workers in the field were Linde, John and Henry Bell, and James Coleman, who in 1877 produced a cold-air machine and with this brought home a cargo of meat from Australia.

It was about this time Sir Alfred Haslam took up the matter, and his great improvement was the invention of a dryer through which the air passed after compression and cooling, but prior to expansion. This successfully solved the problem of the prevention of the formation of snow. He bought up the Bell-Coleman patents, and one of the first Haslam machines was fitted in the R.M.S. *Orient* in 1881. By 1889 some 350 Haslam machines were at work ashore or afloat. In the development of the carbon dioxide and ammonia machines he also took a leading part. There are many types of refrigerators now in use, but the growth of the cold-storage industry has been remarkable, while in 1925 no fewer than 340 ships with a total insulated space of 70,000,000 cubic feet possessed Lloyds' refrigerating machinery certificate. Refrigerating machinery is also used largely in warships for maintaining explosives at a moderate temperature.

Sir Alfred Haslam came of a family long connected with the iron trade of Derby, and the Haslam Engineering Works there grew out of a small iron works belonging to his father. His knighthood was bestowed upon him in 1891 when Queen Victoria visited Derby.

DR. L. P. MANOUVRIER.

IN the *Times* of Jan. 20 appeared a brief announcement of the death of Dr. Leonce Pierre Manouvrier, of Paris, at the age of seventy-seven years. This is a loss to French anthropology which, notwithstanding his advanced age, will be deeply deplored. Manouvrier was Director of the laboratory at the Collège de France of the School of Advanced Studies (Anthropology) and professor of the School of Anthropology. He was secretary-general of the Society of Anthropology of Paris, which he joined in 1889, following Ch. Letourneau as secretary on the death of the latter in 1902. Latterly, Prof. Anthony has been associated with him as *Secrétaire adjoint*. Although Manouvrier never attained the commanding position of his great predecessors in office at the Society—Broca and Topinard—he had long been regarded as one of the foremost of French anthropologists. As a teacher of the School he was pre-eminent. His published work was characterised by its accurate and minute attention to detail, as was shown particularly in his many contributions to the *Bulletin* of the Society of Anthropology. He rarely failed to take part in the meetings of the Society, and his contributions to the discussions were marked by clarity and precision. He was an honorary fellow of the Royal Anthropological Institute of Great Britain, and an honorary or corresponding member of most of the important anthropological societies on the Continent.

BY the death of Frederick Gordon Pearcey at Newport, Mon., on Jan. 26, at the age of seventy years, there passed away the last survivor of the scientific staff of the *Challenger* Expedition. Mr. Pearcey was attached to the biological laboratory of the *Challenger* in 1872 as taxidermist and general assistant, and on the completion of the voyage he assisted Sir Wyville Thomson and Sir John Murray in the *Challenger* Office at Edinburgh, acquiring great skill in identifying species, especially of Foraminifera, on which he wrote several papers. He devised methods for cutting microscopical sections of marine deposits, and became proficient in all branches of practical oceanography and museum arrangement. His alert intelligence and obliging disposition made him a favourite with all contributors to the *Challenger* memoirs. When the last of the *Reports* was published he worked for a time at the Marine Biological Station at Granton and at Millport on the Clyde. In 1889 he went to the Owens College Museum in Manchester. Nine years later he joined the staff of the Scottish Fishery Board, but in 1905 he returned to museum work, going to the Bristol Museum as assistant curator of zoology; there he remained until his retirement after the breakdown of his health last year.

WE regret to announce the following deaths:

Mr. J. J. Lister, F.R.S., distinguished for his work on the Foraminifera and author of the article on Mycetozoa in the eleventh edition of the "Encyclopædia Britannica," on Feb. 5, aged sixty-nine years.

Prof. Thorkild Rovsing, professor of clinical surgery and sometime Rector Magnificus of the University of Copenhagen, on Jan. 13, aged sixty-two years.

News and Views.

The retirement on Mar. 9, under the age clause, of Sir Sidney Harmer from the directorship of the Natural History Museum, South Kensington, will remove from active professional life one who has been for forty years conspicuous for his researches in zoology and influence upon this branch of science. Fellow of University College, London (1884), and later fellow, lecturer, and tutor of King's College, Cambridge, he made the latter his home until in 1908 he came to London as keeper in zoology at the Natural History Museum, afterwards becoming director in 1919. Trained under F. M. Balfour, his first researches were directed to the elucidation of the anatomy, embryology, and position of the Polyzoa; later, his interest shifted to the natural history, evolution, and classification of the group. With Sir Arthur Shipley he edited the "Cambridge Natural History," 1896–1909, which owing to his painstaking care is recognised as giving a complete epitome of the facts of zoology at the dates of publication. He was president of Section D of the British Association in 1908, choosing the Polyzoa as his subject—suggesting that there may be segregation in the formation of a bud analogous to the segregation of characters in the formation of gametes. In recent years his interest turned to the whales, and this was the underlying force in sending out the *Discovery* expedition to South Georgia to investigate these forms. It says much for his enthusiasm and determination that he induced the British Government, in a time of great financial stress, to send out this the greatest British expedition since the *Challenger*, the results of which will be the monument to him as director of the Natural History Museum.

Sir Sidney Harmer's directorship has not been marked by any great changes in the main fabric of the exhibition building or in the arrangements of the exhibits of the Natural History Museum. A new wing to the Museum was projected and actually agreed to before the War, but this has never been proceeded with. It is true that a new spirit building has been erected, and most of the staff dealing with water-living animals has removed there. The space thus vacated in the basement was assigned to entomology; space intended solely for store purposes, but used also as research rooms by the staff. It is not too much to say that the congestion here is appalling, especially as housing has had to be found for the Imperial Bureau of Entomology. The best results, too, are not to be obtained by setting sedentary workers in relatively dark basements. Of new material, the large collection of deposits of the late Sir John Murray is housed in a temporary building in the grounds, and the exhibition of the Cetacea cannot be deemed satisfactory. The present condition of the Natural History Museum reflects the highest credit on the members of the whole staff, but there is no possibility of overlooking the fact that progress on all sides is being seriously impeded by the lack of storage and working space. If storage space is provided. it will be possible so to rearrange and reduce the exhibits as the better to expose their beauty and scientific importance, thus adding to the attractiveness of the Museum to the public.

The Commonwealth Council for Scientific and Industrial Research held its second session last November and made a number of important decisions regarding future policy. Prof. A. C. D. Rivett, a member of the executive committee, will devote his full time to the work of the Council during 1927, as its chief executive officer, having been granted leave of absence for this purpose by the University of Melbourne. Mr. Gerald Lightfoot is to be secretary to the Council. In connexion with work on fruit storage and transport, Dr. Kidd, of the Cambridge Low Temperature Research Station, will visit Australia during the first half of this year in order to survey the position and suggest a comprehensive scheme of work. Dr. W. J. Young, associate professor of biochemistry at Melbourne, will meet Dr. Kidd at Cape Town and with him study existing practice there before proceeding with the investigation of Australian conditions. It is hoped that Dr. Young will take charge permanently of later developments in Australia. Prof. T. Brailsford Robertson, of the University of Adelaide, has been invited to take the position of officer in charge of investigations into problems of the nutrition of stock. He will probably continue his present fundamental researches at Adelaide while organising and developing national investigations prompted by the needs of the wool, meat, and dairying industries.

Inquiries are being made throughout the British Empire by the Commonwealth Council for an entomologist and a mycologist to initiate and steadily develop organisations for research work upon the numerous insect and fungus pests that annually levy great toll on primary industry. A considerable scheme for attacking the diverse problems of the irrigation settlements in the Murray and Murrumbidgee river areas is being put into operation with the hearty co-operation of the departments of the State Governments concerned. Prof. Prescott, of the Waite Agricultural Research Institute, is to be asked to supervise and co-ordinate all soil survey work. The solution of certain problems in these irrigation areas is of importance in relation to possible increased settlement by migration from Britain. Forestry matters are also receiving attention, and it is expected that a prominent officer from the Indian Forestry Service will visit Australia early this year to report upon the establishment of a forest products research laboratory.

In these and other actions the Commonwealth Council is following the definite plan of seeking competent full-time officers to take charge of a number of departments of investigation. Committees will no doubt be formed to assist so far as possible in the work, but the system of relying on such committees to supervise extensive researches, the details of which are carried out by officers acting under their instructions, has been abandoned. It is hoped that the Council will very soon possess a highly trained senior staff and be able to proceed with intensive study of the seemingly innumerable problems which beset Australian industries. For the time being, attention will be directed mainly to primary industries, though decisions to proceed with radio research work and with the provision and maintenance of ultimate physical standards, in close co-operation with the physics departments of the universities and the Defence Department, indicate that advance in other directions will not be long delayed. Throughout its programme the Council aims at the closest possible association with the Department of Scientific and Industrial Research in London, from the officers of which it is receiving very valuable assistance and advice.

The Friday evening discourse on Feb. 4 at the Royal Institution was delivered by Sir Arthur Keith, on "Human Races, Old and New." Five well-marked types or stocks are recognised among the living representatives of mankind: the white or Caucasian type, the Mongolian peoples—between them making up fully seven-tenths of the total population of the world—the black or Negro type, the brown or Dravidian race south of the Himalayas, and the Australoid. However numerous or extensive human migrations may have been in long-past times, they have left the great breeding grounds of the primary races of mankind untouched. How are we to account for the fact that each part of the world is populated by a distinctive breed of mankind? There is only one theory which offers an explanation, and that is the one put forward by Darwin. He held that the most favourable sites for the evolution of new forms were the centres of wide continental spaces. All that we know of the past and present distribution of human races favours this theory. If we accept such an explanation we must regard the Negro, the Chinaman, and the European as the most recent expression of their respective types. Each we may regard as the type of being best adapted for the country and culture in which it has been evolved. On each side of the racial frontiers of the world we find intermediate types.

There has been, beyond any doubt, much intermarriage and intermingling across racial frontiers, but such an explanation, although accepted by the majority of anthropologists, does not, in Sir Arthur Keith's opinion, account for the gradual transition which we usually find in passing from the centre of one racial area to the centre of another. Those who seek to explain the existence of intermediate types by interbreeding of primary forms forget that the first duty of an anthropologist is to account for the primary forms—the Nord, the Negro, the Mongol, or the Caucasian. If evolution is true, and Negro and Caucasian are the descendants of a common ancestor, then we ought to find, just as we do find, a series of intermediate types joining the centres where the new types have been cradled; the extreme and most fully differentiated types represent the older and less-changed forms. Politicians and anthropologists differ altogether in their conceptions as to what constitutes a separate race. The politician concentrates his attention on tradition, language, and spirit; a race, to claim the title in an anthropological sense, must have characteristics which mark it off from all other peoples. In this sense the races of western Europe are very imperfectly separable—not because of the interminglings which have occurred, but because they are branches of the same stock, and time and space have been insufficient to permit more than a partial differentiation.

On Tuesday, Feb. 1, the second lecture of the series being given at Bedford College for Women, London, was delivered by Sir Thomas Heath, who dealt with "Conceptions of the Cosmos in the Classical Period." Sir Thomas reviewed in detail the speculations of the early Greek philosophers. Thales showed little advance upon the popular cosmology derived from Egypt and Babylon; but original thought began with Anaximander (early sixth century B.C.), who held that the earth was a cylinder suspended in equilibrium in the centre of the universe, and explained the light of the heavenly bodies by hollow rings or hoops encircling it, containing fire visible only at one point. He said there were other worlds than ours, and also propounded a primitive theory of evolution. Anaxagoras strikingly anticipated Laplace when he traced the origin of the cosmos to a rotatory movement imposed by mind upon primal chaos and postulated centrifugal as well as centripetal force. While the geocentric conception tended to prevail, and was adopted both by Plato and by Aristotle (who worked out, under the influence of Eudoxus, an elaborate system of concentric spheres to explain the movements of the heavenly bodies), the Copernican theory was anticipated partly by the later Pythagoreans and by Heraclides of Pontus, and wholly by Aristarchus of Samos, who said that the earth revolves round the sun, while the sun and the fixed stars (whose sphere is of immense size) are unmoved. The method of Tycho Brahe was anticipated by Appolonius of Samos in his attempts to explain the movements of the planets. On the physical side, the atomic theory propounded by Leucippus and Democritus and adopted by the Epicureans was remarkably in accord with modern thought. Sir Thomas gave a masterly exposition of much of the detailed astronomical and mathematical work of these early thinkers, whose conclusions, often sounder than their methods, illustrate the saying of Aristotle that "not once nor twice, but times without number, the same thoughts occur to men."

On Feb. 1 the University of Oxford was presented with the most valuable property that it has ever received. The Radcliffe Library, the great dome of which figures so prominently in the best-known of Oxford views; the freehold of the adjacent land on which it stands; the books in the Science Library at the University Museum, and an income of £1500 a year for the upkeep of that Library, were all conveyed by the Radcliffe Trustees as a gift and were gratefully accepted. The Radcliffe Library is a scientific institution of international importance, and so its future government, on which so much depends, is a matter for grave deliberation. Its success hitherto has been due to the strict observance of the Radcliffe Trust as defined by Dr. Radcliffe in his will, namely, the appointment of a librarian. For some unpublished reason neither the Trustees nor the Radcliffe electors have done anything to carry out their duty in this respect during the past three years that have elapsed since the death of the last eminent holder of the office, Dr. Jackson. During these three years the Library has lost many books by theft, the scientific world has been deprived of one of its most useful officials, and the Radcliffe Trust has not been carried out.

The reason sometimes suggested for the inactivity of the Radcliffe Trustees is that this unique and admirably arranged scientific Library is to be reduced to the condition of an appanage of the Bodleian, a library that is primarily managed in the interests of literary and classical scholars, and the lack of accessibility of its books makes it unsuited to the every-day needs of the student of science. Moreover, scientific literature in the Bodleian is rarely quite up to date; a recent visit disclosed the fact that the 'current' number of Nature was nearly two months old. Many have found it impossible to do scientific work in so lethargic an atmosphere, and all who are well acquainted with the condition obtaining in the two libraries fear that the substitution of Bodleian control for control by an independent scientific Radcliffe librarian will be a disaster rather than a gain to the cause both of academic and of international learning.

The University of Oxford has every reason to be grateful to the generosity of the Evans family. During and after his keepership of the Ashmolean Museum (1884–1908) Sir A. J. Evans presented his Cretan collections as well as the magnificent series of Anglo-Saxon and Teutonic ornaments collected by his father, Sir John Evans, that have gone so far to elucidate the early history of Ægean and North European culture. His brother, Dr. Lewis Evans, has given those splendid examples of early scientific instruments which are now one of the established sights of Oxford in the Old Ashmolean Building, where they form the nucleus of a museum for illustrating the history of science. Now Sir Arthur has presented yet another of his father's collections, in illustration of the palæolithic, neolithic, bronze, and early iron ages not only in Britain but also in many parts of central, southern, and northern Europe, including a fine series of ancient British gold ornaments and of objects from the well-known cemetery of Hallstadt. A large number of the specimens have been figured in the classical works of Sir John Evans on the stone age, and with these are coming a number of Romano-British relics and some Egyptian antiquities of great variety. It is not easy to draw the line between civilisation and barbarism, but the united gifts of the Evans family now cover both sides of the line, and in a manner which can never be accomplished again.

The Italian Government has voted the sum of two million lire for the purpose of resuming the excavation of Herculaneum according to the plan drawn up by Prof. Majuri of Naples and approved by Signor Mussolini and the Minister of Public Instruction. This sum will cover the initial expenses of beginning excavation in the coming spring, and further sums, it is said, will be forthcoming year by year as the work proceeds. The greatest obstacle in pursuing the excavation hitherto has been the fear that the villages of Resina and Portici, which overlie the site, would have to be expropriated and the inhabitants evicted. According to a well-informed writer in the *Italian Mail* of Jan. 29, this step is not now considered necessary. Excavations will be carried on at the south-east of the ruins at a point midway between Resina and Torre del Greco, use being made of the shafts left by former excavators to penetrate the city. As much as possible will be laid open, but those parts which cannot be opened up will be lit by electric light. Both what is known of the status of the inhabitants of Herculaneum at the time of its destruction, and previous finds of objects of art and manuscripts, make it difficult to overestimate the additions to our knowledge of Italian life and culture at the beginning of our era, and of classical literature which may follow, should the Italian Government carry out the excavations on the scale projected.

Preparations are now being made for an expedition of anthropological investigation among the tribes of the south Abyssinian frontier. The expedition is to be conducted by Mr. J. H. P. Driberg, the author of a valuable book on the Lango, and formerly an official in East Africa, who will go out under the auspices of the Royal Anthropological Institute. If the arrangements are sufficiently far advanced and the funds received towards the expenses justify, the expedition will leave England some time during the month of April. The object of the expedition will be to investigate the physical anthropology and social organisation of the Pagan Galla of southern Abyssinia, and of various nomad tribes in Abyssinia and Kenya. Tribes on the north-eastern frontier of Uganda and the south-eastern Sudan will be on the way to Abyssinia, and it is hoped that it may be possible to get into touch with the Turkana of Kenya, a very important group of people which is but little known. In addition to the ethnological investigations, zoological observations will be made and economic plants, as well as plants and drugs used by the natives for magical purposes, will be collected. Mr. Driberg will be accompanied by Dr. J. O. Beaven, who will be responsible for physical anthropology, pathology, and zoology as well as the bulk of the photographic work. If funds allow, the expedition will last for three years, about eighteen months of which will be spent in a preliminary investigation of the smaller tribes before going on to the main objective, the Galla.

The expedition has the support of the Royal Society and the British Association for the Advancement of Science, both of which bodies have made grants towards the expenses.

Mr. Gordon Hume, in *Discovery* for February, directs attention to an anomalous conclusion, drawn from the results of an inspection of strata and their contents on an excavated site in King Street, Cheapside, which would appear to suggest caution in the chronological interpretation of archæological evidence in the City of London area. In a section measuring 4ft. 3 in. in depth were revealed eight archæological levels—seven well-marked, the eighth confused—between virgin soil (18 ft. below street level) and an upper stratum consisting of a series of deposits superimposed closely one upon another. Samian ware was found in varying frequency in levels 1, 2, 6, 7, and 8—in the last named merely a tiny fragment. The eight layers, on the usual reckoning for the city of London of one foot per century, would represent at least four hundred years; yet, as stated, throughout the series there occurs Samian ware which is usually attributed to the period A.D. 1 to 110, and no specimen of post-Trajanic pottery was found. It would therefore seem either that material accumulated on this site at a rate unheard of in the rest of London—it shows no signs of exceptional circumstances such as the existence of a rubbish heap—or else that, if the four feet of deposit does really represent four centuries, Samian pottery of the first-century type was used and manufactured in London so late as the fifth century. As all the London Samian ware belongs to the type of that of the King Street site, Mr. Hume finds himself left with the dilemma that either the accepted scheme of dating of Dragendorff and Déchelette requires reconsideration or that the rate of accumulation of soil in London represents problems yet to be solved.

The subject of Prof. Eddington's third Gifford Lecture in the University of Edinburgh on Friday, Feb. 4, was "The Running-down of the World." It began with a consideration of the random element in the world, the study of which rests on the law of chance, a law on which the physicist, perhaps, places greater trust than on any other accepted law of Nature. The scientific measure of that random element in the world is called entropy. From the point of view of the philosophy of science, Prof. Eddington thinks that entropy must be ranked as the great contribution of the nineteenth century to scientific thought. It made a reaction from the view that all that is essential can be found by applying a microscope to the world. While Einstein's theory of spherical space has removed all difficulty as to the infinity of space, we are still confronted with the dilemma of an infinity of time, especially the difficulty of an infinite past. But between us and the infinite past lies a more pressing difficulty, namely, the winding-up of the universe. The organisation of the energy of the world is being continually reduced by the continual increase of the random element; in the past we must attribute a greater and greater degree of organisation, and it is impossible to follow such an increase back indefinitely.

While deprecating any hasty inference that this involves the interference of a creator of organisation at a not infinitely-remote time in the past, Prof. Eddington thinks we must recognise that current physics rests on the view that there is in the world not only chance but also the antithesis of chance. We may not be justified in relating this 'antichance' at all closely to that which appears to our consciousness in the guise of purpose and design. Chance requires its complement 'antichance' as much as positive electricity requires its complement negative electricity, and physics should not be regarded as wedded to one rather than to the other. The 'fortuitous concourse of atoms' which has been so much of a bugbear is now definitely limited in physics to a well-recognised type of system, namely, a system in thermodynamical equilibrium; physicists, however, would be the first to protest against the idea that that condition is typical of the world in general.

Further details of the information acquired by the Dutch-American Expedition to New Guinea during its stay among the pygmies of the Nassau Mountains have been issued by the Smithsonian Institution of Washington. Dr. Stirling, the leader of the expedition, states that the pygmies are mild-mannered, quiet, and unobtrusive, and not in the least nervous. They are energetic agriculturists and entirely vegetarian, cultivating sweet potato, sugar-cane, taro, raspberries, tobacco, and a number of other plants not recognised. They raise pigs in considerable numbers and have dogs. Various implements of stone are in use—axes, knives, hoes, wedges, and so on. They have no knowledge of iron. Their principal weapon is the bow and arrow. In an interview with a representative of the *Times* at Port Said which appeared in the issue of that paper of Feb. 2, Dr. Stirling gave a further account of the culture of the negritos, in the course of which he referred to their use of tobacco in pipes and in cigarettes, and their trade by means of barter or with cowries as their medium of exchange. Each village is administered by a headman and elders, but there are no chiefs. Before marriage the bridegroom has to undergo an ordeal in which arrows are shot at him, and when a wife is divorced the top joint of the index finger is cut off; the same mutilation is performed on the other fingers for succeeding divorces. Polygamy is practised. Their religion is animistic, and they have a great faith in the virtue of amulets The average height of the pygmies is said to be 4 ft. 2 in. and their colour quite black.

On Dec. 27 last, Prof. M. Pupin, the retiring president of the American Association for the Advancement of Science, gave an address on "Fifty Years' Progress in Electrical Communications." He lays stress on the important part played by Maxwell's electromagnetic theory in the development of telegraphic and telephonic science. He also points out how invaluable thermionic tubes are in everyday work. Perhaps undue importance is attached to those who gave the first experimental demonstrations of the new methods. For example, in 1853 William Thomson proved theoretically that in certain cases the discharge of a Leyden jar is oscillatory, and Feddersen deserves great credit for verifying this experimentally six years later. But Thomson's formulæ are still quoted in every treatise on radio communication. Heaviside describes clearly how the variables of his distortionless circuit are connected, and if the adjustment is not perfect we can easily see how it can be improved by varying any one of the four variables. A knowledge of what Maxwell has done does not help us to do this. One interesting point Pupin mentions is that, since Faraday, every great advancement in the art of electrical communication has originated in the research laboratories of the universities, and not in the test-rooms or research laboratories of manufacturing companies. He points out that the natural electrical disturbances which take place in electrical circuits, such as static disturbances, fading, earth currents in cables, etc., deserve close study, as they may enable us to find the secrets of the natural processes going on in the sun, the central power-station which supplies the moving power to all our organic and human activities.

An account issued to the Press by the New York Electrical Society of an address on fused quartz given by Dr. Berry, of the American General Electric Co., would be singularly misleading to any one not familiar with the subject. We read that fused quartz is a "new and remarkable material" which by its property of inexpansibility "opens new scientific advances in fields as distinct from each other as astronomy and fire prevention." From this one might be led to conclude that fused quartz is an American discovery of recent date; and so with each application of the material to science and industry—the material being newly discovered, its applications must also be new. The application of fused quartz to fire-sprinkler bulbs, and again the suggestion of its use to replace glass in astronomical instruments and the like, scarcely merit the designation of "new scientific advances." Sprinkler bulbs of fused quartz were made commercially in England so long ago as 1912—and there seems little novelty in the suggested application of quartz to the second purpose mentioned, although the successful manufacture of blocks 8 ft. to 10 ft. diameter would certainly be an advance.

One of the activating motives of the work on fused quartz done in England in the last twenty odd years, has been the commercial production of really large pieces of transparent fused quartz (such as discs 2 ft. and upwards in diameter)—as yet such pieces are not available. The paper mentioned above suggests that sizeable 'blocks' of transparent quartz are available in America for astronomical purposes. This reference, occurring as it does in a paragraph immediately following reference to glass "blocks 8-10 ft. diameter," would make clearer reading if the actual size of the fused quartz 'blocks' were specified. No novelty attaches to the suggestion to use fused quartz for astronomical purposes. An actual installation will, however, be a matter worthy of adulatory comment. Reading further, we find that Dr. Berry 'discloses' the use of fused quartz in experimental biological studies of the effects of ultra-violet radiation; what recent obscurity there has been about such a use must have been purely local. It is not to be doubted that the American scientific worker is as an individual anxious to acknowledge prior discovery and development in a field of activity which he may enter. It is unfortunate, therefore, that a statement issued by a well-known American society should be so misleading, and we are forced to the conclusion that there must have been in this case a singular lack of knowledge of the facts.

The botanical library of Capt. John Donnell Smith of Baltimore, consisting of some 1600 carefully selected and beautifully bound volumes, with his plant collection of more than 100,000 specimens, which was presented to the Smithsonian Institution of Washington twenty-two years ago, has only now been deposited there, and constitutes the most valuable botanical gift ever made to the Institution. The library includes some valuable and very rare volumes, and is particularly rich in works descriptive of tropical American plants, especially those of Central America. At the time of presentation to the Smithsonian, Capt. Smith's herbarium was the finest in existence for Central America, and is of great scientific interest because it includes so many type forms. Besides American species, the collection includes sets of plants from all over the face of the globe, China, Tibet, Central Asia, India, Australia, Africa, and has already been the basis of much important work by the Smithsonian botanists. The results of the labours of one of America's most enthusiastic and indefatigable botanists thus become available for general reference.

The January number of the *Empire Cotton Growing Review* (vol. 4, No. 1) is the first to be issued by the new publishers, Messrs. P. S. King and Son, Ltd., 14 Great Smith Street, London, S.W.1. The journal is the organ of the Empire Cotton Growing Corporation, and the work and aims of that organisation should be more widely known than they are at present. Any attempt to further the economic independence of the Empire is worthy of support; and it is the endeavour of the Corporation to extend the cultivation of cotton within the British Empire, for "an increase in the number of sources of raw cotton is a matter of the most urgent importance." With this end in view, the services of skilled plant physiologists, pathologists, geneticists, economists, and others have been concentrated on improving and extending the cotton yield, and the results of the researches of those specialists are published in the Corporation's journal. The present issue contains some interesting and useful articles, and preserves an even balance between the scientific and economic aspects of the problem. For those engaged in any branch of the cotton industry the "Notes on Current Literature" at the end will be found invaluable.

The Rockefeller Foundation has issued a fifth series of "Methods and Problems of Medical Education." Descriptions are given of the Departments of Anatomy, Pathology, Bacteriology and Public Health, and Physiology of the Washington University School of Medicine, St. Louis, Mo.; of the Departments of Physiology, Botany, Anatomy, Zoology, Biochemistry, and Pharmacology of McGill University, Montreal; of the Institute of Pathology of the University of Utrecht, and others. The descriptions are by the heads of the Departments, are copiously illustrated and show plans of the buildings, while details of finance and research are also given. "Le Service de Prophylaxie Mentale du Département de la Seine, Paris," and the "Centre Régional de Toulouse pour la lutte contre le Cancer" are also described. Dr. Bela Schick gives the method of charting clinical records of children's diseases adopted at Mt. Sinai Hospital, New York, and Profs. Estor and Pech, of Montpellier, describe an apparatus for viewing an operation at a distance from the surgeon, or even in an adjoining room. It consists of two large mirrors, one above the other; the upper mirror receives the image of the operation and reflects it down into the lower mirror in which it is viewed, a special illuminating lamp being employed.

The first congress of the International Association of Soil Science will convene on June 13 in Washington, D.C. The congress will be followed by a field excursion to visit the various important soil belts in the United States. Opportunity will also be given to the delegates to acquaint themselves with various agricultural industries, some of the leading agricultural experiment stations and, in general, with the agricultural resources of the country. The association is made up of six international commissions, each acting under an independent chairman, and the programmes of the commissions are now in course of preparation. Each will consist of papers presented by invitation by outstanding investigators in the respective fields, and of papers presented by various workers in the different branches of soil science, by members or non-members of the association. Titles of the papers to be presented and brief abstracts in English, French, and German should be sent to Dr. J. G. Lipman, New Brunswick, New Jersey, U.S.A. The congress will bring together workers interested in the different problems of soil classification, soil analysis, fertilisation and treatment, as well as the relation of the soil to plant growth. Extensive exhibits of various soil types, of apparatus used in soil analysis, and of the soil microflora and microfauna will be held during the congress.

Sir Ernest Rutherford will deliver the twelfth Guthrie lecture to the Physical Society of London on Friday, Feb. 25, taking as his subject "Atomic Nuclei and their Transformations."

With the view of encouraging original research in sanitary science, scholarships of the yearly value of £300, plus an allowance for apparatus, etc., are being offered by the Grocers' Company. The scholarships will be tenable for one year, but renewable for a second or third year. Applications must be made before the end of April to the Clerk of the Grocers' Company, Grocers' Hall, E.C.2, upon a form obtainable upon request.

The Edison Medal of the American Institute of Electrical Engineers for 1926 has been awarded to Dr. William David Coolidge, the assistant director of the research laboratory of the General Electric Company, for the production of ductile tungsten and the fundamental improvement of the X-ray tube. Dr. Coolidge, who is an honorary member of the Röntgen Society, was born in Hudson, Massachusetts, on Oct. 23, 1873, and is a graduate of the Massachusetts Institute of Technology and a Ph.D. of Leipzig. After some years as a teacher of physical chemistry at Massachusetts he became associated with the General Electric Company in 1905, and was made assistant-director of research three years later.

Prof. J. Brontë Gatenby, Zoological Department, Trinity College, Dublin, informs us that, in conjunction with Dr. E. V. Cowdry, of the Rockefeller Institute, N.Y., he is editing a new edition—the ninth—of Lee's "Microtomist's Vademecum." He invites research workers and others to forward to him, as soon as possible, any new information suitable for incorporation in the forthcoming edition. It is not proposed to include bacteriological technique.

The seventieth birthday of Prof. D. A. Low, of East London College, was celebrated on Feb. 9 by a dinner arranged by his old students. Prof. Low came from Dundee, and after serving his apprenticeship as an engineer, studied at Owen's College, Manchester, and at the University of Glasgow. In 1887 he was appointed headmaster of the Day Technical School for boys at the People's Palace, London, and on the formation of East London College he was made professor of engineering, a post which he held for twenty-six years. During this time he served on the Faculty of Engineering of the University of London, later becoming secretary, and on his retirement he was made emeritus professor. Prof. Low is the author of many textbooks on machine drawing and allied subjects.

At the general committee which closed the fourteenth annual meeting of the Indian Science Congress held at Lahore during the week Jan. 3-8, the president, Sir J. C. Bose, announced that since meeting in Bombay the past presidents had associated themselves in a presentation to Dr. J. L. Simonsen on his retirement from the office of honorary general secretary. In taking this action the past presidents were confident of thus giving tangible form to the feeling among members of the Congress, that the development of scientific thought and practice in India will remain heavily indebted to Dr. Simonsen, who has not only served as honorary general secretary during thirteen years, but to whose activity and enthusiasm in its early stages the foundation and survival of the Congress are substantially due. The general committee approved this action of the past presidents, and unanimously elected Dr. Simonsen president of the fifteenth annual meeting of the Indian Science Congress to be held in Calcutta during the week Jan. 2-7, 1928.

A new and cheaper impression of Prof. A. N. Whitehead's "Science and the Modern World" is to be published almost at once by the Cambridge University Press, and at a later date a new impression of the same author's "Religion in the Making." The same house also promises a new book by Dr. C. Davison entitled "Founders of Seismology," being in effect a history of the study of earthquakes ranged round the founders of the science from John Bevis and Elie Bertrand down to Prof. John Milne and Prof. Fusakichi Omori.

Applications are invited for the following appointments, on or before the dates mentioned:—A full-time assistant lecturer in pharmaceutics at the Cardiff Technical College—The Principal, The Technical College, Cardiff (Feb. 19). A keeper of the laboratories of the Royal Horticultural Society at Wisley—The Secretary, Royal Horticultural Society, Vincent Square, S.W.1 (Feb. 22). An assistant entomologist at the Rothamsted Experimental Station—The Secretary, Rothamsted Experimental Station, Harpenden (Feb. 26). A lecturer in the department of botany (special subject—plant physiology). King's College, London—The Secretary, King's College, Strand, W.C.2 (March 2). A professor of physiology in the University of Birmingham—The Secretary, The University, Birmingham (April 23). A head of the agricultural department and farm director of the Harper Adams Agricultural College, Newport, Salop—The Principal, Harper Adams Agricultural College, Newport, Salop. An assistant bacteriologist at the Wellcome Tropical Research Laboratories, Khartoum—The Director of the Laboratories. A head of the department of bakery and confectionery of the Borough Polytechnic Institute—The Principal, Borough Polytechnic Institute, Borough Road, S.E.1. A technical officer, grade II., at the Royal Aircraft Establishment, South Farnborough, for duties in the technical supervision of the application of all equipment used in aeroplanes built under contract for the Air Ministry—The Chief Superintendent, Royal Aircraft Establishment, South Farnborough, Hants (quoting A 127).

Our Astronomical Column.

Comets.—An orbit of comet 1927 *b* (Reid) has been telegraphed from South Africa, from which it appears to have passed perihelion in 1926, so it will presumably be numbered as 1926 VII. The orbit indicates that the motion in R.A. in the former telegram was erroneous; it was sent as +44 sec., but it should be about +11 min. The comet has begun to travel northward, and should be visible in Europe about the middle of March.

$$\begin{aligned} T &= 1926 \text{ Dec. } 30{\cdot}54 \text{ U.T.} \\ \omega &= 224^\circ\ 45' \\ \Omega &= 108\ \ 42 \\ i &= \ \ 83\ \ 40 \\ \log q &= 9{\cdot}87708 \end{aligned}$$

Annals of Moscow Observatory, Vol. 8, No. 1, contain definitive elements of comet 1904 I. (Brooks) by M. S. Kasakov.

$$\begin{aligned} T &= 1904 \text{ Mar. } 7{\cdot}138756 \text{ G.M.T.} \\ & \left.\begin{aligned} \omega &= \ \ 53^\circ\ 32'\ 34''{\cdot}0 \\ \Omega &= 275\ \ 47\ 25{\cdot}4 \\ i &= 125\ \ \ \ 7\ 42{\cdot}5 \end{aligned}\right\} 1904{\cdot}0 \\ e &= 1{\cdot}0013646 \\ \log q &= 0{\cdot}432643 \end{aligned}$$

As the comet was observed from April 16, 1904, until June 5, 1905 (besides a photograph on May 14, 1903, not used in the above orbit), the hyperbolic character is well established.

Mercury as an Evening Star.—Mercury will be well placed as an evening star in the second half of February, reaching elongation on Feb. 25, when it is 18° from the sun and 8½° north of it. The latter point is of importance for increasing its height above the horizon at sunset. Herr Carl Schoch, who is well known for his researches in ancient astronomy, contributes an article to the *Stegliter Anzeiger* of Jan. 20 in which he points out the assiduity with which Mercury was observed in Babylon, and the importance of the *arcus visionis*, or length of time of visibility of the planet. On Feb. 22 it will set $1^h\ 40^m$ after the sun, and should be visible to the naked eye for nearly half an hour. This is the best evening elongation of the present year. The presence of Venus some 5° further east will add to the interest.

Herr Schoch asks naked-eye observers to send him notes of the duration of visibility of Mercury, that he may compare them with the Babylonian records.

Photographs of Mars in 1926.—An extensive series of photographs of Mars during September and October of last year was made by Mr. F. E. Ross at the Mount Wilson and Lick observatories. A preliminary account of the results obtained are given by him in the *Astrophysical Journal*, vol. 64, p. 243. A special enlarging camera was used, attached to the 60-inch telescope at Mount Wilson, and photographs were taken in light of five different colours (ultra-violet, blue, yellow, red, and infra-red) with the aid of suitable filters. At the Lick Observatory the camera was attached to the 36-inch refractor, the photographs being taken only in yellow and infra-red light. The photographs discussed in this preliminary paper are extremely interesting in showing that surface markings appear only in light of long wave-lengths (yellow to infra-red), whereas clouds and atmospheric effects require short-wave light to render them visible in the photographs. This is the reverse of what might be expected, especially as the prominent rim light in the ultra-violet photographs seems to point to the existence of a strongly scattering atmosphere. The decrease of diameter in the infra-red photographs, discovered by Wright in 1924, is confirmed. The method appears to be a very valuable one for studying atmospheric conditions in Mars, and a further discussion of the photographs will be awaited with interest.

Research Items.

The Peopling of the Earth.—Dr. Aleš Hrdlička in No. 3, vol. 65, of the *Proceedings of the American Philosophical Society*, reviews conclusions on the place of origin and distribution of man put forward in 1921 in the light of the evidence collected by him in his recent journey through parts of Europe and Asia, Australia, and South Africa. On the question of the origin and cradle of mankind, he holds to the view that this must be sought in western and south-western Europe, with probably an early extension of the species, on one hand towards central Europe, and on the other, over the watershed of the Mediterranean. It is probable that by the time the last or Würmian glaciation was approaching, man existed in only one general form—the Neanderthal, which persisted for a very long time into post-glacial times. The view that Neanderthal is a separate species which completely died out is erroneous. It is a necessary stage of man's evolution, and if *Homo sapiens* is given another place of origin, say Asia, a Neanderthal phase must be postulated there. Probably he became much reduced in numbers in western Europe and his place was taken by transitional Aurignacian man who was nearing the modern type, having developed from an extension of the Neanderthal eastwards beyond central Europe, which afterwards returned westwards as Aurignacian man to the place of his Neanderthal forefathers. After the last glacial period there is a rapid extension of culture, and man for the first time in his history becomes capable of furnishing a surplus of numbers needing an extension of his domain. It was during this time that the foundation was laid for man's differentiation into the older human stocks and races. Apart from the corroboration of the above views, three, or rather four, conclusions emerge as a result of Dr. Hrdlička's journey. A link between the Negritos of Africa and of south-eastern Asia has been found in India; it is clear that the Australian (and Tasmanian) is one of the more fundamental races of the world with close connexion with our own ancestral stock; there are in Asia remnants of the old yellow-brown stock from which is derived the American Indian, *e.g.* the Tibetans; and lastly, in Australia and South Africa new types of white man are developing.

Northern Tungus Migrations.—An examination of the ethnological affinities of the Goldi of the Amur and Ussuri rivers by Prof. S. M. Shirokogoroff in Vol. 57 of the *Journal of the North China Branch of the Royal Asiatic Society* has afforded the author an opportunity to offer suggestions towards the elucidation of the obscure question of the date and course of the various Tungus migrations. The Goldi, sometimes known by the Chinese name of *Yu-pi-ta-tse*, *i.e.* Fish-skin Barbarians, on account of the use of this material for articles of dress, belong to the southern branch of the Tungus linguistic family; their language may perhaps be regarded as a branch of spoken Manchu, but it shows elements characteristic of northern Tungus dialects. Their culture shows traces of the northern Tungus complex, as well as of Palæasiatic influence. Recently, Chinese influence has been brought to bear upon them by colonisers. From neolithic times to the present day their territory, it is known, has been the scene of struggles between various groups, Palæasiatics, Koreans, Mongols, Tungus, and, later, Chinese. Archæological evidence—walled cities, cemeteries, etc.—shows that at times it has been thickly populated. A comparative study of the cultural and linguistic elements of the Goldi complex shows that this people is of mixed character and origin, which may be explained as an absorption of the northern Tungus, who went from north and west to the south and east, by the southern Tungus and perhaps Palæasiatic groups. Four different waves of Tungus migration can be distinguished. The first wave occurred before the tenth century, and brought various groups of northern Tungus, probably reindeer breeders and including the Goldi, to the lower Amur, Ussuri, and Sunjari basins. The second wave, about the twelfth century, occupied the territory left by the reindeer breeders. A third wave in the seventeenth century, after the Manchus depopulated the Amur valley, led to certain tribal redistributions in and about eastern Transbaikalia. The fourth wave, which began in the nineteenth century and still continues, is one in which the last of the northern Tungus stock living south of Yakuts are moving eastward into the Amur Government and on to the Manchurian plateau.

Ancient Ships.—The ships of early explorers were described by Mr. G. S. Laird-Clowes in a recent lecture to the Royal Geographical Society, in which he pointed out how imperfect is the record of early shipping, not merely in actual specimens but also in pictorial representation. Among early forms of vessels the only ones that have been preserved are one or two small Egyptian processional boats; two Roman vessels, not yet raised from the bottom of Lake Nemi; a portion of a lighter of about A.D. 270 found in the Thames; a Frisian ship; and two Viking ships. In the British Isles, beyond the Thames lighter and some dug-outs of doubtful age, there is nothing earlier than a barge of the time of William and Mary, another nearly a century later, and then Nelson's *Victory* and the *Implacable*; or as Mr. Laird-Clowes puts it, there is a blank in the preservation of actual ships from Roman times until the seventeenth century. The pictorial record is less inadequate, but it consists largely of ships broadside on and so gives comparatively little detail of the build and method of construction. Moreover, it is concerned mainly with large ships; the small vessels, which were of chief importance in exploration, were seldom drawn in any detail.

Grafting in Planaria.—Prof. H. W. Rand and Amy Browne describe (*Proc. U.S. Nat. Acad. Sci.*, vol. 12, Sept.) the technique they have employed in their grafting experiments on *Planaria maculata* undertaken with the view of ascertaining whether regeneration of a head at an exposed anterior cut surface may be inhibited by the presence of a head grafted relatively near this cut surface. The difficulties of the grafting operation arise from the extreme softness and delicacy of the tissues, the mobility of the pieces and the contamination of the cut surface with mucus. A 3·5 per cent. solution of pure acid-free gelatin in distilled water was made and allowed to cool until it began to stiffen, and was then poured on to cold glass slides where it set, forming a layer about 1 mm. thick. Two Planaria, preferably narcotised by chloretone, were taken, and from the side of the body of one was excised a piece of tissue, leaving a wound appropriate in size for the reception of the graft. The wound was made deep enough to interrupt the lateral nerve cord. This animal having been placed on the prepared gelatin surface, the head was immediately excised from the second Planaria and placed with its cut surface against the wound surface of the first one, and strips and fragments of moist gelatin were packed tightly around to prevent separation of the grafted head from the body. The slide was placed in a moist chamber for 18 to 24 hours, after which the gelatin was carefully picked away and the graft compound transferred to a small dish of pond water. Eight successful grafts of a head on to the side of a body were obtained. After the graft had become well healed in place, the animal's original head was removed. The question was: Will the presence of the foreign head in close proximity to the wound affect the regeneration of a head which would take place in an ordinary beheaded Planaria? In one case the stock head was removed and regenerated five successive times, but in other cases it would appear that retardation and inhibition of regeneration was due to the presence of the grafted head.

New Mollusca from Mexico, Central and South America.—Three short papers are before us dealing with new mollusca from these regions. Mr. W. B. Marshall describes eleven new species of "Land and Fresh-water Mollusks from Central and South America" (*Proc. U.S. Nat. Mus.*, vol. 69, art. 12) belonging to the genera Cyclodina, Succinea, Ampullaria, and various Unionidæ. Dr. Paul Bartsch, in continuation of a paper published in 1924, treats of "Additional new Mollusks from Santa Elena Bay, Ecuador" (*Proc. U.S. Nat. Mus.*, vol. 69, art. 20). As in the original note, they are marine genera, mostly Turbonilla, Pyramidella, and Odostomia. The same author also writes on some "New Urocoptid Land Shells from Mexico" obtained by Mr. C. R. Orcutt during his recent botanical explorations (*Proc. U.S. Nat. Mus.*, vol. 70, art. 4). Sixteen species of Holospira supposed to be new are described and illustrated.

Botany and Hydrology.—Oscar Edward Meinzer has investigated the uses of plants as indicators of ground water (*Jour. Wash. Acad. Sciences*, vol. 16, No. 21, 1926). He groups desert plants into two general classes according to the adjustments they make for the scarcity of water. On one hand are the true xerophytes, depending for their scanty supply of water on the rains that occur at long intervals, and during periods of drought maintaining themselves in a nearly dormant condition; on the other hand are those plants, termed by the author "phreatophytes" or "well plants," which grow where they can send their roots down to the water table. These plants group themselves in zones and communities according as the topography of the surface varies the depth of the water table. Thus salt grass (*Distichlis spicata*) indicates water 8 ft. to 12 ft. from surface, while mesquite (*Prosopis juliflora*) can reach water so far as 50 ft. below ground. After twenty years of hydrological work, and contrary to popular belief, the author is unable to establish any definite relation between the occurrence of phreatophytes and the quality of the ground water, or to suggest that any species that can grow in even moderately alkaline soil will invariably indicate potable water. Even in desert country, a substantial supply of water is thus available, and the loss of water per acre due to transpiration is probably less than the quantity required to irrigate useful crops. Pumping, however, is an expensive operation, and it is suggested that those hundreds of thousands of acres of desert land should be made productive rather by the cultivation of such promising phreatophytes of economic value as alfalfa (for seed mostly), Bermuda grass, and pecan.

Recent Lowering of Sea-level.—It is well known that Daly has presented evidence supporting the view that a world-wide lowering of sea-level, amounting on an average to about six metres, has taken place during post-glacial time. This has been recently extended by the observations of Wentworth and Palmer on the islands of the North Pacific. They find a lowering of the ocean level of 12 to 15 feet. W. A. Johnston, however (*Am. Jour. Sci.*, 1926, p. 253), has failed to find evidence of such a relative movement along the Pacific Coast of Canada. A further contribution to the subject of recent movements of the strand line is now made by A. F. Buddington in the *Am. Jour. Sci.*, 1927, p. 45. He has examined more than four thousand miles of coast in south-eastern Alaska, and he states that wherever the conditions have been favourable, remnants of relatively uplifted sea-cut rock benches are found near the present level of high tide. The estimated lowering of sea-level is between 12 and 16 feet. This, however, is but the last of a series of post-glacial uplifts. Near Juneau, old beach deposits have been found at elevations of 600 feet or more, and well-marked platforms produced by marine planation occur at various levels up to 200 feet.

Land Movements during the Japanese Earthquake of Sept. 1, 1923.—The remarkable elevations and depressions measured in the bed of Sagami Bay have already been referred to in Nature (Mar. 29, 1924, vol. 113, pp. 473-474). The corresponding movements on land form the subject of a valuable paper by Major-General H. Omura, of the Land Survey Department (*Bulletin of the Earthquake Research Institute*, vol. 1, 1926, pp. 65-68). Immediately after the earthquake this Department began the revision of precise levelling, and during the following years, from 1924 onwards, it has been engaged in carrying out a revision of the triangulations over the central region. The admirable map which accompanies the paper shows the changes of level in the land surrounding Sagami Bay, zones of uplift and depression for every fifth of a metre being represented, from +2 metres and upwards to −1·2 metres and below. The more important elevations occur along the coast of Sagami Bay and in the Boso peninsula. The main area of depression lies inland to the north-west of the bay, and it is noteworthy that one of the principal zones of depression is about 30 miles north-north-west of the centre of the first disturbance, that is, it is close to the centre of the second movement (see Nature, Jan. 22, 1927, vol. 119, p. 139).

Igneous Rocks of Mount Girnar.—More than twenty years ago Dr. J. W. Evans made a representative collection of rocks from the Girnar and Osham Hills in Kathiawar. A systematic examination of the types represented has now been made by M. S. Krishnan, and his results are published in the *Records of the Geol. Surv. India*, 58, 1926, p. 380. Almost simultaneously a field and structural study of the Girnar rocks appeared in the *Journal of Geology*, 34, 1926, p. 289, by K. K. Mathur, V. S. Dubey, and N. L. Sharma. These two papers taken together have greatly extended our hitherto scanty knowledge of the phases of igneous activity which followed the great outpourings of the Deccan plateau-basalts. At Girnar the basalts were domed up by a laccolith in which olivine gabbro, diorite, and monzonite crystallised. A circular system of fractures around the dome was intruded by granophyre; and, in the gabbro, dykes of nepheline-syenite and lamprophyres are found in close association. The differentiation of the parent magma is attributed to fractional crystallisation, and support is given to Bowen's hypothesis of the origin of nepheline-syenite, involving the removal of orthosilicate molecules by volatile fluxes. A series of analyses is presented by Dr. Krishnan, and it is noteworthy that the variation diagram constructed from the results is of the broken and jerky type which seems to correspond with the suggested process of fractional crystallisation.

Gabb's Californian Fossil Gastropods.—The well-known American palæontologist, W. M. Gabb, described in two volumes, published in 1864–69 by the Geological Survey of California, the fossils collected by the members of that Survey. He did not, however, designate type specimens or indicate type localities, items required in present-day palæontological research, while in some cases his figures were restored and embodied parts of more than one specimen. Mr. R. B. Stewart now seeks to rectify all this so far as the Gastropoda are concerned (*Proc. Acad. Nat. Sci. Philad.*, vol. 78), and after careful study of the original specimens deposited by Gabb with the Academy of Natural Sciences of Philadelphia, and those which had drifted into other collections, has carefully described and illustrated the now selected types. More than 150 species have been dealt with, but 20 are still missing. It has been considered necessary to create 14 new genera. The 13 plates of figures from retouched photographs by Miss H. Winchester are good and should amply meet the requirements of students.

Radio in the Whaling Industry.—The use of radio telephony by fleets of whaling ships has made the whaling industry a much less strenuous one. When one of the vessels, equipped with a ½-kilowatt Marconi telephone set, sights a number of whales, possibly after several weeks' searching, the other ships of the same fleet are immediately informed by telephone, and all can then make for the best spot for hunting. The 'factory ship' that also accompanies the fleet is simultaneously directed to the most suitable position for taking charge of the catches. A simple code is employed, so only the ships concerned can interpret the messages. The apparatus used is highly efficient, as messages have been heard up to distances of two thousand miles. Until a few years ago, whales were caught by harpooning from rowing boats. Now fast steam launches equipped with 1000 horse-power engines are used for the pursuit. Harpoons are projected from guns instead of being thrown by hand. Practically all the carcase is converted into oil, cattle cake, and other marketable commodities. On several ships this season, Marconi direction finders have also been fitted. As the magnetic compass is of little use in the Antarctic regions, these finders, which are independent of the earth's magnetism, have proved of great value. Like the telephone sets, the direction finders are worked by the harpoon-gunner and require no special operator. The Ross Sea, which is enclosed by an ice barrier with only one seasonal outlet, can now be safely invaded and large catches have been made in it.

Detection of Internal Flaws in Rails.—For some years it has been known that it is possible to detect internal flaws in steel samples of uniform section by magnetic means. The method has not hitherto received much attention, since it is necessary to thread on to the end of the sample the magnetising and test coils. A recent improvement which eliminates this difficulty is described in a paper by Masuhiro Suzuki in *Science Reports*, Tohoku Imp. Univ., vol. 15, No. 4, p. 479. The method has been applied to rails actually in service with important results. The magnetisation of the steel is effected by a large horseshoe electro-magnet which rests a very short distance above the surface of the rail on small rollers. Between the poles is one test coil which need only be placed on the surface. Any irregularity in the rail is then detected by a deflexion of a galvanometer connected to this coil as the whole apparatus is traversed along the rail. Flaws, segregated areas, and overstrained regions are then readily detected. The latter is an important point, since portions of the steel which, although not yet actually flawed are potential flaws, are clearly picked out. As an example of this may be mentioned periodic irregularities found in a new rail free from marked segregation or flaws. The author ascribes these to the effects produced in the rail-straightening process after it had been rolled. Although the present work is confined to rails, the modified method is applicable to a large number of similar examinations such as tyres and ropes.

Thermal Decomposition of Ozone in the Presence of Hydrogen.—R. O. Griffith and K. McKeown have extended their experiments on the catalytic effect of gases on the thermal decomposition of ozone to include the effect of hydrogen on the same reaction at 78° and 100°. Details of the work have been published in the *Journal of the Chemical Society* for Dec. In addition to the deozonisation process, water is formed by the reaction, $H_2 + O_3 = H_2O + O_2$, and the interpretation of the results is more difficult. The velocity coefficients of the two reactions show that the catalytic effect of the hydrogen is positive, and a possible explanation of the results, involving a series of intermediate reactions, is given.

Effect of Sunlight on Cotton.—The effect of sunlight on cotton fabric is the subject of No. 1016 of the Aeronautical Research Committee's Reports and Memoranda (London: H.M. Stationery Office, 1926. 1*s.* net), by G. Barr and Isabel Hadfield. It has been found that the determination of the viscosity of a solution of cotton in cuprammonium hydroxide forms a much more sensitive method of following the deterioration in sunlight than that used in the past, namely, the change in tensile strength. After exposure, the cotton shows increased reducing properties, and it is evident that chemical and not merely physical change has taken place, although further work on fabric exposed in the absence of oxygen is necessary before it will be possible to decide to what extent the change in the fabric is an oxidation process.

A New Transformation of Cobalt.—Measurements have been made by Hakar Masumoto (*Science Reports*, Tohoku Imp. Univ., vol. 15, No. 4, Oct. 1926) of the electrical conductivity, thermal expansion, heat changes, and magnetic properties of cobalt at high temperatures. For the purest sample, all of these show a discontinuity around 477° C. on heating and 403° C. on cooling. From X-ray analysis it is shown to be probable that below this temperature cobalt crystallises as close-packed hexagonal material, while above it is face-centred. Both forms are ferromagnetic. The effects of iron and nickel on this change have been investigated, and in each case the added metal lowers the temperature of the change rapidly. Especially is this the case with iron, about 4 per cent. of which element lowers the change point to 0° C. Some observations are made on the changes in the iron-cobalt and nickel-cobalt systems respectively which occur below the solidus. So far as the latter alloys are concerned, they appear to form one series of solid solutions throughout. The system iron-cobalt is more complex, and as the iron content is raised the structure at room temperatures passes from close-packed hexagonal to face-centred cubic, and then finally to body-centred cubic at about 21 per cent. of iron. In each case there is a small zone in which the mixed phases are found.

Meteorology and Air Routes.

THERE are few forms of transport which are not influenced to some extent by meteorological conditions, but there is none which makes greater demands on meteorological science and practice than the aeroplane and the airship. The importance which is attached by the Air Ministry to the provision of the necessary meteorological advice and organisation in connexion with the development of Empire air routes is rendered evident by a document recently issued under the title of "The Approach towards a System of Imperial Air Communications" (H.M. Stationery Office, price 5s.). This document consists of the memorandum by the Secretary of State for Air laid before the Imperial Conference, 1926, together with the report of the Imperial Air Communications Special Sub-Committee. The memorandum contains appendices giving a clear statement of the principles governing the application of meteorology to air navigation, both as regards investigational work and as regards the provision of a ground organisation along the routes. At the same time, the main portion of the memorandum sets out, in the section on airships, some general remarks on the bearing of meteorological conditions on airship navigation, supported by very interesting examples of the results to date of an intensive meteorological investigation of the projected England-Egypt-India airship routes, illustrated by charts well reproduced in colours. Meteorological work for airships is in the hands of a specially created division of the Meteorological Office, and it is hinted that the aim of the work on the England-India routes is to provide for the airship pilot, information in atlas and handbook form analogous to that which has long been available to seamen.

Examples of average thunderstorm and upper wind conditions show that the 'normal' routes may differ outward and homeward, and also from month to month. Further, the pilot will find that in particular cases departures from the 'normal' route for the month will be advantageous. The memorandum reminds us that "the air and its currents are to the aircraft what the oceans and their currents are to the ships, . . ." and proceeds: "A high wind, even of gale force, should cause no more danger or discomfort to an aircraft in flight in free air than an increase of speed in an ocean current to a surface vessel in mid-ocean; but there are, however, certain atmospheric disturbances, such as tornados or waterspouts, and violent vertical currents associated with thunderstorms and line-squalls, which do constitute a potential source of danger to airships." It is then pointed out that these must be avoided by suitable choice of route, the report continuing: "It is particularly on long-distance airship flights that such alteration of route will be made in order to avoid adverse and utilise favouring weather conditions. It will, in fact, be the rule rather than the exception, for the commander of an airship to choose his route between any two points for each separate flight, having regard to the meteorological conditions prevailing at the time." An example is reproduced from a special series of daily weather charts for a whole year covering Europe, N. Africa, and a large part of Asia, being prepared from past data to study such problems. This shows how the pilot, given the weather chart and forecasts, could have made a quicker passage in better weather from London to the Mediterranean via the west coast of France than by the more direct route viâ the Rhone valley.

It is not alone the navigation of airships which has made demands on meteorology. Airship mooring is requiring, for its ultimate perfection, a knowledge of the finer wind and thermal structure of the lower layers of the atmosphere and the changes with time, beyond that existing at present. The former is being investigated at Cardington (Beds.) by a special network of electrically synchronised anemometers with very open time-scale, while it is proposed to instal instruments on a mast at Ismailia (Egypt) to give a continuous record of the lapse-rate of temperature in the first 200 feet or so above the desert surface. It is thus evident that airship development is calling for information which is of very special interest to meteorologists, so that the science of meteorology should itself benefit considerably in meeting these demands.

Attention has not been confined to the England-India airship route. An appendix contains the results of a preliminary survey of meteorological conditions with the view of delimiting areas within which main Imperial airship routes may be expected to develop, and these are shown in a chart. The flying areas are in the form of strips, some hundreds of miles wide, extending from base to base. They lie mostly over the sea. In addition to the routes to Canada across the North Atlantic, there are alternative routes to South Africa, namely, via the west coast and via the Red Sea and east coast. Australia and New Zealand are reached both from South Africa and also as an extension of the England-India route. The passage from South Africa is outward by the northern boundary of the 'Roaring Forties' and back in the south-east trade belt. That from India to Australia is wholly across the ocean to south-western Australia, avoiding the well-known Java thunderstorm area.

The recommendations of the Imperial Air Communications Sub-Committee, afterwards adopted by the Conference, take cognisance of the importance of active co-operation of the Dominions in providing meteorological facilities if Imperial Air Routes are to be developed successfully.

Mycology in Great Britain.

THE British Mycological Society is one of the most vigorous scientific bodies in Great Britain, and this is reflected in its Transactions, of which vol. 11, Parts 1 and 2, edited by Carleton Rea and J. Ramsbottom, has recently been published (London: Cambridge University Press, 15s. net). Amongst its most useful activities are the spring and autumn forays, when members visit some specially chosen locality and spend several days studying lichens, mycetozoa, and fungi in the field. These forays are almost unique training grounds for students of systematic mycology, and at the same time give opportunity for the very valuable work of recording local floras and thus adding permanently to mycological science. The published lists, as for example those of the Tintern and Dublin Forays of 1925 which appear in this issue, nearly always show a number of additions to the British flora and not infrequently species new to science.

The present issue contains the president's address, which is of interest as giving the views of a herbarium systematist on certain controversial problems. That such a one can write "one of the great hopes of the systematist is the phytopathologist" shows a very commendable broadening of a point of view more usual in herbaria. Mr. Ramsbottom discusses the 'species concept' at some length but in what cannot be regarded as a very helpful manner, and his suggestion that Prof. Lotsy is a writer of undergraduate essays on this subject is wide of the mark. The more important portions of the address are those in which attention is directed to the widespread occurrence of heterothallism and hybridisation in fungi and to the increasing acceptance of behaviouristic criteria in specific delimitation.

The question of heterothallism has been studied by Dr. Derx, who records its occurrence in the genus Penicillium. Problems of strain and species in the genus Colletotrichum are discussed in relation to diseases of certain tropical crop plants by Dr. Small and Mr. M'Donald in two very interesting papers.
